The Goulstonian Lectures

ON

A CONTRIBUTION TO THE LOCALISATION OF CEREBRAL FUNCTION, BASED ON THE CLINICO-PATHOLOGICAL STUDY OF MENTAL DISEASE.

Delivered before the Royal College of Physicians of London on March 1st, 3rd, and 8th, 1910,

BY JOSEPH SHAW BOLTON, M.D. LOND., F.R.C.P. LOND.,

FELLOW OF UNIVERSITY COLLEGE, LONDON; SENIOR ASSISTANT MEDICAL OFFICER, LANCASTER COUNTY ASYLUM, RAINHILL, ETC.

LECTURE I.

Delivered on March 1st.

MR. PRESIDENT AND GENTLEMEN,—In thanking you for the honour you have done me by your invitation to deliver the Goulstonian Lectures for the present year, I would at the same time apologise for my presumption in choosing as my subject such a vexed and intricate question as the localisation of cerebral function. I have but one excuse to offer—namely, that in my researches I have attacked this subject by a somewhat different method from th se hitherto adopted, and have thereby obtained results which appear to me partly to confirm and partly to elaborate the conclusions arrived at by certain other and more experienced workers. As my present investigations have already occupied a considerable period of time, it being now 14 years since their commencement and 10 years since my first paper on cortical localisation was published, I think I may fairly claim that the conclusions at which I have arrived are neither hasty nor ill-considered, and I therefore trust that you will regard these, and also the evidence which I am about to lay before you, as not entirely unworthy of your attention.

HISTORICAL REMARKS.

I do not propose to enter into a historical retrospect of the investigations of the past 40 years, as for my purpose it is sufficient to refer briefly to those of the past decade. With regard to the earlier researches, I would remark that the experimental method of investigation, which was introduced by Fritsch and Hitzig and by Ferrier, and continued by numerous workers from whose names it would be invidious to make a selection, may be considered to have served its purpose with the publication of the researches of Sherrington and Grünbaum. These, by linking together the conclusions arrived at by the experimental and the histological methods, resulted in the belated recognition of the neglected histological investigation of Bevan-Lewis and Henry Clarke on the cortical localisation of the motor area, and gave an impetus to the latter method which has already been followed by a considerable amplification of our knowledge of the structure and functions of the cerebrum.

The last, but not the least important, of the researches to which I must refer before dealing with the published work of the past few years are those of Flechsig on the development of the human brain by a study of the process of myelination. The division of the cortex cerebri by this investigator into the two great classes of "sensory centres" and "centres of association" raised a storm of discussion and dissent which is almost unprecedented in the history of research, and which, but for Flechsig, would have overtaken the workers of the past decade. Though many of the results obtained by Flechsig have failed to obtain credence, largely perhaps through the frequency with which he modified them in successive publications, his broad generalisation has successfully withstood the fire of criticism, and forms the origin, if not entirely the basis, of our present knowledge of cortical localisation by histological methods. In my personal opinion, which is based on my experience of the great differences which exist in the degree of development of fœtal and infantile brains of approximately the same age, Flechsig was injudicious in applying directly to the adult cerebrum the results he obtained from the investigation of such brains; but, of course, it is easy to be wise after the event, and it is probable that the researches of Flechsig would have attracted less attention had they excited less dissent.

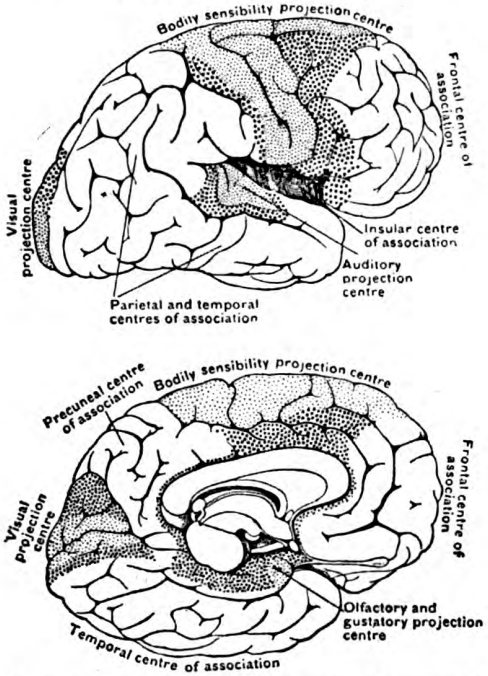
During the past decade numerous publications have appeared on the subject of cortical localisation by histological methods. In these several publications the whole cortex cerebri of man, and in many orders of mammals, has been mapped out into various histologically different regions, and in some instances proof of the functional significance of these has also been adduced. Further, the mode of evolution and functional significance of the different cell laminæ of the cortex cerebri have been discussed from both the ontogenetic and the phylogenetic aspects.

As I purpose in these lectures to deal solely with the human cerebrum, it is unnecessary for me to refer, except as occasion serves, to such investigations as concern the cortex of the lower mammals. Amongst the publications which bear on cortical localisation in man, those of two authors stand out prominently—namely, the "Histological Studies" of Campbell and the series of monographs published since the year 1902 by Brodmann. These authors have independently and elaborately mapped out into histologically different areas the whole human cortex cerebri, as well as the cortex cerebri of certain orders of mammals. The human maps of these authors, whilst differing considerably in detail, agree with one another much more than either of them resembles the maps of Flechsig. I have already indicated one reason why the map of Flechsig cannot be applied directly to the adult cerebrum. It will also be evident to you that, owing to the low development in the fœtus of the later evolved spheres of association, the projection areas must of necessity differ considerably in their relative size and distribution in the fœtus and the adult. Further, without going so far as Elliot Smith, who from the point of view of causation closely correlates fissuration and histological differentiation, although these differ very considerably in the adult cerebrum, I certainly regard histological differentiation as one of the causes of fissuration, others being arterial supply, and probably also certain mechanical conditions of growth. It is hence not surprising that the projection areas of Flechsig, taking for granted their correctness in the fœtus, do not bear the same relationship to the main cerebral fissures as do these areas in the adult cerebrum.

HISTOLOGICAL DIFFERENTIATION OF THE CORTEX.

I shall now show on the screen the maps of Flechsig, for comparison with the maps of Campbell and of Brodmann. (Fig. 1.) It will be noticed that the visuo-sensory area is much larger than in the adult, as is also the bodily sensibility projection centre, which in the adult lies entirely behind the fissure of Rolando. Flechsig, however, I may remark, expressly states that the majority of the sensory projection fibres pass behind the central fissure. At the period when the experimentally obtained Rolandic area was considered to be both pre- and post-Rolandic, and to be sensori-motor in function, its supposed distribution closely resembled the fœtal bodily sensibility area of Flechsig, and the two were regarded as identical. Now, however, the "motor" and "sensory" areas are regarded as separate and as lying on either side of the furrow of Rolando. It is, by the way, necessary to remark in this connexion, lest I should appear to disregard a recent article by Sir Victor Horsley, that I intend to refer to this when dealing later with the structure and functions of the psychomotor area.

[On the plate which was then exhibited were arranged for comparison two sets of maps by Campbell, published in the years 1904 and 1905, and the maps of Brodmann.]



In view of the great difficulties involved in the cutting up, blocking, sectioning, orientating, and reproducing in diagram form of the cortex of entire human hemispheres, considerable differences might well be expected in maps prepared by two totally independent investigators. It is, however, difficult to understand the well-marked differences which exist in the case of the two pairs of diagrams of Campbell, one of which is contained in a preliminary communication and the other very shortly afterwards in his monograph, since the fissuration of the two is identical. In the case of the prefrontal, the frontal, the parietal, and the visuo-psychic regions, the differences in distribution are very considerable, in view of the fact that, in the case of a particular brain, either the lines of demarcation should be very exact or they should be left indefinite.

On the face of it, the maps of Campbell appear to be

217154

the more diagrammatic and the less accurate of the two sets, and this impression has been confirmed from my personal acquaintance with many regions of the cortex, particularly the frontal lobe and the visual areas. I would also refer to a recent paper by Gordon Holmes on the histology of the post-central gyrus, in which the findings of Brodmann are confirmed. I am nevertheless of the opinion, without disputing in any way the entire accuracy of these particular maps of Brodmann, that the exact differentiation of the greater portion of the grey mantle into such relatively precise areas as are the Betz-cell area and the visuo-sensory area, will be attended with great difficulty owing to the probability that considerable differences exist in the case of different individuals, and especially so in the case of the poorly developed brains which are often met with in asylum practice. As an illustration of my meaning I will show a diagram of six occipital regions in which many years ago I precisely mapped out and obtained proof of the functional significance of the visuo-sensory area. It will be noticed that both the shape and the apparent extent of this area differ considerably in the several cases, even when difference of age or the existence in some of long-standing blindness is allowed for. Case 1 is a normal male, aged 55 years; Case 2, a female, aged 17 years, is an example of chronic insanity with epilepsy; Case 3, a female, aged 27 years, is an example of chronic insanity with blindness from infancy; Case 4, a male, aged 30 years, is an example of chronic insanity with long-standing blindness; Case 5 is a normal infant, a male, aged three months; and Case 6 is an example of anophthalmos, aged one month. If such individual differences exist in a projection area of early evolution and stable organisation, it is, to say the least, likely that still greater individual differences exist in the later evolved and later specialised regions of association.

FIG. 1 (AFTER FLECHSIG).

The "centres of projection" and "centres of association" of Flechsig. The small dots are placed in the chief focus of each centre of projection. Around these chief foci are the regions to which a smaller number of fibres of projection pass; these are indicated by larger dots. The areas, which represent the different cortical spheres indicated by Flechsig as the result of his embryological studies, are not directly comparable in either extent or distribution with the corresponding areas in the adult cerebrum.

As another illustration, this time of probable individual variation only, I will refer in a few words to the recent researches of Marie concerning aphasia and the functions of the area of Broca. It may be accepted, as I have elsewhere remarked, that the thesis of this author with regard to the intellectual impairment exhibited by all aphasics is true, at any rate, if such cases be studied by methods familiar to the alienist. It is not, however, probable that motor aphasia is invariably the result of anarthria + sensory aphasia, although, on the other hand, it is doubtless true that anarthria + sensory aphasia necessarily give rise to the symptomatology of classical motor aphasia. It is certain that in the case of many persons Broca's speech centre is rightly disrated by Marie, whereas it is extremely probable that in others Broca's area is part of the educated psychomotor area, in which case its permanent loss would result in temporary "motor aphasia" with temporary interference with voluntary thought. Such variability with regard to the individual distribution of the special part of the psychomotor area which subserves the evolution of speech is, in my opinion, the only possible explanation of the widely divergent views which are held by equally competent observers.

Before concluding my reference to the histological differentiation of the cortex I wish to mention quite briefly another question of importance. I have indicated the probability, if not certainty, that individual variations occur in the actual extent occupied by the several histologically differentiated areas which have been described. Whilst histological differentiation probably indicates the limits of possible educability, it does not, however, necessitate the existence of functional activity, as Bianchi appears to believe.

A very obvious illustration of this truth may be seen in the motor exhibitions evolved by the psychomotor area, which as you are aware constitute the sole objective indications of cerebral activity. Whether we consider the infinite variety of skilled movements, the numerous highly complex written and spoken languages, or the wonderful gamut of expression and gesture, of which the intelligent human subject is capable, we see in each case gross individual differences in educability. Histological differentiation probably supplies the key with regard to individual potentialities, but it is doubtful whether any single individual of the race has ever even approached the limits of possible educability.

I will trouble you with but one further illustration—namely, the remarkable manner in which such serious disabilities as congenital or early deprivation of the senses of hearing or sight may be compensated for by education. A person suffering from congenital or early loss of hearing is necessarily dumb, and, unless he live in association with other individuals suffering from the same disability or be educated by special means, his mental functions differ little from those of the anthropoid primates. In such persons under either of these conditions the auditory disability is compensated for by shrewdness of vision, and the speech disability by the evolution of descriptive mimicry to a high standard. The deaf and dumb think by mimicry, just as voluntary thought in normal persons occurs by the preliminary activity of the articulatory part of the psychomotor area, which is important evidence, if such be needed, in favour of the truth of the latter thesis. A normal individual may "think to himself" by means of invisible laryngeal and respiratory movements. A deaf and dumb person does not possess the same involuntary ability to hide the results of psychomotor activity during voluntary thought. Further, if such be taught lip-language they readily learn to communicate with normal persons inexperienced in the special mimicry of the deaf and dumb. On the other hand, the congenitally or early blind acquire language just as do ordinary non-reading and non-writing individuals, and in the absence of special education exhibit little or no defect of the mental functions. In such persons, however, loss of sight is usually compensated for by marked hyperactivity of the sense of touch, and by means of special type the blind are able to acquire education which is often little, if at all, inferior to that of many normal individuals.

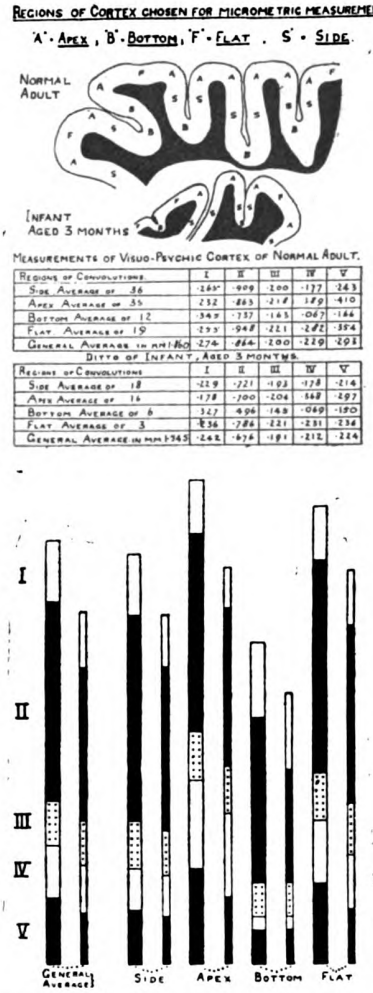
After these general remarks I pass to the subject I propose laying before you—namely, the evidence which I have obtained from the clinico-pathological study of mental disease, with regard to the functional significance of certain special cortical areas.

I have hitherto confined my attention to four of the numerous regions into which the cerebral cortex is divisible: the visuo-sensory area, which is the best example of the sensory projection spheres; the visuo-psychic zone, which is one of the regions of special cerebral association; and the

prefrontal and precentral regions. As necessary preliminaries, I shall now describe in detail the method which I have employed, and also the manner in which the cortex cerebri undergoes evolution during fœtal life and infancy.

METHOD OF INVESTIGATION.

The method which I am about to describe, and which I have employed for many years, is that of micrometric measurement of the primary cell and fibre laminæ of the cortex. Neither in detail nor in results is it in any way comparable with the macro- and micro-metric mensuration of grey matter which has been performed by several workers for many years, and it is therefore not necessary for me to refer further to this.



For reasons which I shall indicate later I am accustomed to subdivide the cortex, for the purposes of measurement, into the five primary laminæ from which it has been evolved —namely, (1) the outer fibre lamina or superficial layer; (2) the outer cell lamina or pyramidal layer; (3) the middle cell lamina or granule layer; (4) the inner fibre lamina or inner line of Baillarger, which in certain regions contains such bodies as the Betz cells and the solitary cells of Meynert; and (5) the inner cell lamina or polymorphic layer. These five laminæ may more or less readily be identified in all parts of the neopallium, though they differ in their degree of development in different cortical areas. For example, in the psychomotor area the third lamina is of minimal depth and can only be detected by careful examination. On the other hand, in the visuo-sensory area the third lamina is of great depth, the granule layer being duplicated by the interposition in its midst of the fibre layer of Gennari, in which terminate the fibres of the optic radiations.

For the micrometric examination of the cortex it is, however, not sufficient merely to determine the laminæ which it is proposed to measure. Granted that accurately vertical sections are obtained, it is further necessary to define the exact regions of the convolutions which are capable of measurement. In theory the flat external surface of the convolutions is the ideal region, and in certain fœtal brains it is the only one which is available. In practice, however, its sole employment is impossible, if only for the sufficient reasons that a trustworthy number of situations is rarely available and that its degree of development varies greatly, being very different over broad and narrow convolutions. I consequently employ four regions of the convolutions, and from these prepare a general average measurement. These regions are the *flat surfaces* or external parts between fissure lips, the *apices* or fissure lips, the *bottoms* of fissures, and the *sides* of fissures at some point between the apices or fissure lips and the bottoms of the fissures. These regions are shown in the diagram (Fig. 2). It is, perhaps, hardly necessary to remark that in any given section, though it be cut ever so truly, many obliquities exist and only a certain number of regions can be selected. In fact, it is by no means easy to obtain the necessary number of regions for measurement, and it sometimes happens that cases of promise have to be rejected, even after all the sections have been cut and stained. The four well-defined regions to which I have referred are alone capable of accurate micrometric measurement, and for reasons which I shall now give it is possible, after a sufficient number of measurements from these have been averaged, to obtain a trustworthy general average measurement from the four which can be employed for the comparison of case with case.

[Reasons were then given for the choice of these special regions and for their conjoined employment for the preparation of a general average measurement. The methods employed for the preparation of material were referred to, and certain details were given with regard to the method of micrometric measurement.]

The special regions of the human cortex cerebri which I have hitherto dealt with by this method are the visuo-sensory, the visuo-psychic, and the prefrontal, as the most satisfactory examples available of projection, special associational, and higher associational cortex. The reasons for this selection will appear later. I have in all measured 54 regions in 38 hemispheres, which were obtained from 37 cases of various types, including 3 fœtuses, 2 still-borns, 3 infants, 4 normal cases, and 25 examples of various types of mental disease, grading from the idiot with very deficient cerebral evolution, through imbeciles, recent chronic and recurrent non-demented lunatics, and partially demented lunatics, to the gross dement with marked cerebral dissolution. Of the 54 regions measured, 15 are visuo-sensory, 15 are visuo-psychic, and 24 are prefrontal. The visuo-sensory and visuo-psychic results are from the same cases, and in theory it would appear desirable that all the regions should have been examined in every case. In practice, however, this has been impossible owing to the laborious nature of the work and the length of time it has been in progress. It has also been found to be unnecessary, on the one hand, because the differences in measurement are well marked and definite, and on the other because the results of prefrontal measurement are of a different type from those obtained from the visuo-sensory and visuo-psychic regions. I may add that it has in consequence been possible up to the present to measure a much larger series of cases than would otherwise have been available. I have, however, specially selected a suitable well-marked case, and measured all the three regions, in order to obviate such a possible

FIG. 2.

This figure illustrates the method of micrometric measurement. In the upper portion of the figure are shown the four regions of the convolutions, which alone are capable of satisfactory measurement. In the middle part the results of the micrometric measurement of the visuo-psychic cortex of the normal adult and of an infant aged three months are given. In the lower portion the different cortical laminæ are shown graphically. These from above downwards are (1) the outer fibre or superficial lamina; (2) the outer cell or pyramidal lamina; (3) the middle cell or granule lamina; (4) the inner fibre lamina or inner line of Baillarger; and (5) the inner cell or polymorphic lamina. On the left hand side are shown the general average measurements obtained from a normal adult and an infant aged three months respectively; and on the right hand side the average "side," "apex," "bottom," and "flat" measurements from which these general average measurements are produced.

criticism and to prove the points to which I have just referred.

I purpose demonstrating in the second lecture that the essential physical basis of mental disease consists on the one hand in an imperfect development of the cell laminæ of the cortex, which is of the nature of a true sub-evolution, and on the other in degrees of decrease of the cell laminæ which are of the nature of a true involution or dissolution, since such decrease in depth takes place in the converse order to that in which the cell laminæ are developed during the process of normal growth. As one of the necessary preliminaries to this demonstration it is therefore desirable to describe in some detail the normal mode of evolution of the lamination of the cortex. For this purpose I shall employ the prefrontal region, since this is the portion of the cerebrum which is the last to be normally evolved, and also the area in which are present in maximum intensity those indications of sub-evolution and involution which occur in cases of mental disease.

EVOLUTION OF LAMINATION OF THE CORTEX.

The plates which I am now about to exhibit are intended to show from the general point of view the manner in which the lamination of the cortex becomes evolved. All the micro-photographs of this series are of exactly the same magnification.

[A photograph representing the right hemisphere of a human fœtus of about four months was then exhibited. The fissure of Sylvius and a depression which occupies the site of the future fissure of Rolando are present, as also are numerous vascular grooves.]

In the micro-photograph (Fig. 3) is shown a section of the prefrontal cortex of this hemisphere. This will be seen to consist of a layer of undifferentiated neuroblasts covered by a superficial layer of neuroglia, into which irregular masses of neuroblasts project. The neuroblasts are most closely packed towards the surface and, at about the level of the lower trisection, indications exist of commencing differentiation of the nerve cells. The cortex has not begun to laminate, and its total depth is less than half of that of the normal adult.

[A photograph was then shown of the left hemisphere of a fœtus of about six months. The brain is somewhat larger and firmer, and the main fissures are defined or appearing. The numerous vascular grooves seen in the previous hemisphere have largely or entirely disappeared, and the prefrontal region of the cortex consists simply of a flat external surface.]

The prefrontal cortex of this case, as is seen in the micro-photograph (Fig. 4), shows little increase in depth but definite signs of the commencement of the process of lamination. The inner cell lamina or polymorphic layer is being separated from the rest by the development of the inner fibre lamina or inner line of Baillarger. The middle cell lamina or granule layer is visible, owing to the shape and mode of aggregation of its constituent cells, and the outer cell lamina or pyramidal layer can also be made out, and exhibits a partially columnar arrangement of its constituent cells in its lower two-thirds and a massing together of the cells in its upper third. It will be at once evident to anyone familiar with the appearance of the adult cortex that development is taking place from within outwards and that the superficial laminæ, especially the outer cell or pyramidal, are as yet of very deficient depth, the last being only about one-fourth of the adult normal.

It will be noted, on comparing the fourth and sixth months fœtuses, that the development of lamination is coincident with greater firmness of the brain and disappearance of the numerous vascular grooves, rather than with any notable increase in the complexity or size of the hemispheres. Microscopically, however, an important advance has occurred —namely, the commencement of the process of lamination and a cleavage of the neuroblasts into an upper and a lower portion. In view of the evidence I shall produce with regard to the functions of the inner cell lamina I would remark that this early cleavage of the partially differentiated neuroblasts of the cortex into an upper and a lower portion is an occurrence of the greatest significance.

[A photograph was then shown of the right hemisphere of a fœtus of seven to eight months. The magnification is somewhat less than that of the preceding and following brains. The fissuration is completed with the exception of the less important subsulci, and the brain has a general resemblance to that of the adult.]

As is shown in the micro-photograph (Fig. 5) marked progress has taken place with regard to the development of the cortex and the differentiation of the nerve cells. The inner cell lamina is clearly marked off by the inner fibre lamina from the middle cell lamina, and the outer cell lamina or pyramidal layer shows a notable increase both in the depth of its lower part and in the degree of differentiation of the constituent cells of this. The upper portion of this lamina is still in a poorly differentiated condition, and the aggregation of its embryonic constituent cells is by contrast more visible than is the case in the fœtus of six months.

[In the next photograph was shown the unstripped right hemisphere of a stillborn male infant. The resemblance to the adult appearance of the brain is now well marked.]

In the micro-photograph (Fig. 6) it will be seen that the cortex now exhibits a general resemblance to that of the adult. The nerve cells have largely taken their permanent form, and, being less embryonic and smaller, appear less crowded. A further important factor in causing less aggregation of cells is the increased superficial area of cortex and the consequent smaller number of cells in a section of the same thickness. The outer cell lamina or pyramidal layer is, however, still little more than one-half of the adult normal depth, and exhibits a very obvious aggregation of embryonic cells in its upper part.

In contrast to the preceding illustrations, the following micro-photograph (Fig. 7) shows the depth and general appearance of the adult normal cortex. The magnification is four-fifths of that of the preceding micro-photographs. The great increase in the depth of the outer cell lamina or pyramidal layer which has occurred is very evident.

It was originally my intention to follow the further development of the cortex in children of different ages, but I found that such notable individual differences in the degree of the development of the cortex occurred as precluded the possibility of obtaining definite results. This truth is the anatomical counterpart of the known great individual differences in degree of mental development which exist in infants and young children.

In the next diagram (Fig. 8) are shown, in percentages of the normal, the general average measurements which I have obtained from the prefontal cortex of a number of cases. They very clearly indicate the point to which I have just referred. The second case, though it falls well into series with the remainder, exhibits certain differences in the depth of the fourth and fifth laminæ which are due probably to the fact that all the measurements are from the flat external surface owing to the absence of fissures. The fourth and fifth cases exhibit the individual differences in degree of development which I found to occur in two stillborns; and the case in the sixth column, that of a marasmatic infant of retarded general development, is also interesting in that the outer cell lamina is of less depth than that of the second stillborn, whilst all the other laminæ are of almost exactly the same depth as are those in the latter. Further, the diagram shows quite definitely that the laminæ are evolved from within outwards, and that the inner cell lamina approaches the adult normal depth at birth, at which date the middle cell lamina is about three-fourths and the outer cell lamina still little more than one-half of the adult normal depth.

With regard to the date at which evolution of the cortical laminæ occurs, I have at present merely sufficient evidence to show that it takes place earlier in the visuo-sensory area (projection sphere) than in the visuo-psychic (zone of special association), and earlier in the latter than in the prefrontal region (zone of higher association). This evidence is shown in the following diagram (Fig. 9), in which are collected a series of observations on the cortex of certain fœtuses, infants, and adults. The following are the chief points illustrated in the figure. In the visuo-sensory area of the infants of 1 and 3 months the whole of the cell layers have attained to almost the normal adult depth, and the outer cell layer is rather better evolved in the former than in the latter, in spite of the existence of congenital blindness in that case. On the other hand, in the visuo-psychic zone none of the layers are so far evolved, and the outer cell layer of the infant of one month is much shallower than that of the infant of three months. The visuo-sensory cortex is thus obviously evolved earlier than is the visuo-psychic. A

FIG. 3.

FIG. 4.

FIG. 5.

FIG. 6.

FIG. 7.

FIG. 3.—The prefrontal cortex of a fœtus of four months. × 94 diameters. The cortex has not begun to laminate, and consists solely of a superficial layer and a layer of undifferentiated neuroblasts.

FIG. 4.—The prefrontal cortex of a fœtus of six months. × 94 diameters. The process of lamination has commenced. L.I. = outer fibre lamina; L.II. = outer cell or pyramidal lamina; L.III. = middle cell on granule lamina; L.IV. = inner fibre lamina; and L.V. = inner cell or polymorphic lamina.

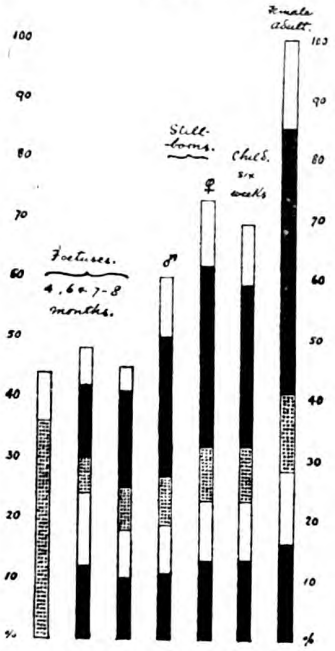


FIG. 5.—The prefrontal cortex of a fœtus of seven to eight months. × 94 diameters. L.I. to L.V. as in Fig. 4. It will be noted that L.II., the outer cell or pyramidal lamina, though the latest to develop, has already become the deepest layer of the cortex.

FIG. 6.—The prefrontal cortex of a stillborn male infant. × 94 diameters. The cortex has begun to lose its embryonic characters. The outer cell or pyramidal lamina (L.II.) is still less than one-half of the adult normal depth. L.I.-L.V. as in the preceding figures.

FIG. 7.—The prefrontal cortex of a normal adult. × 72 diameters. The magnification is four-fifths of that of the preceding micro-photographs. L.I.-L.V. as in the preceding figures.

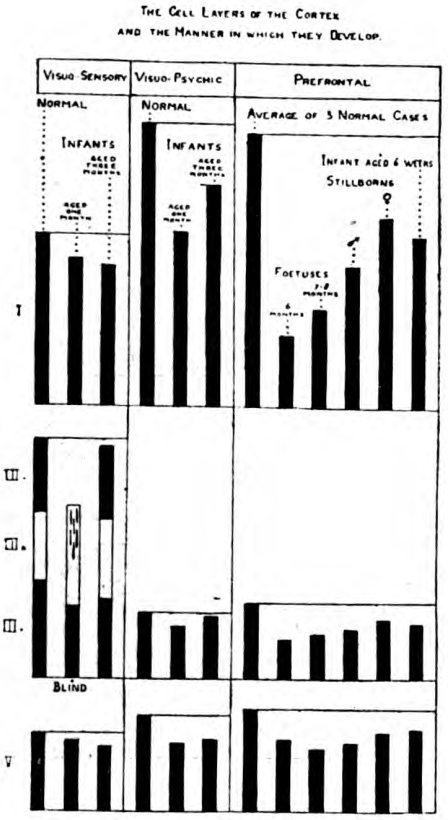
further interesting point shown in the diagram is the low evolution of the middle cell lamina or receptive layer of the cortex of the congenitally blind infant of one month, and the almost adult development of this in the infant of three months. The same detail is visible in the case of the visuo-psychic region, and this is alone sufficient to hall-mark the visuo-psychic region as a zone of special visual association, especially when it is noted that this lamina is in the infant of three months of practically the adult depth, whereas the inner cell lamina of this case is by no means so well developed. In other words, the granule or receptive layer of the visuo-psychic zone follows the order of its evolution in the visuo-sensory area in being ahead of the inner cell lamina in its degree of development.

FIG. 8.

The figure shows, in percentages of the normal, the general average measurements of the prefrontal cortex of a series of fœtuses and infants. The laminæ from above down are as in the preceding figures. The illustration indicates that the cortex evolves from within outwards, the inner cell lamina being the first to appear and rapidly attaining almost to the adult depth, and the outer cell lamina the last, this lamina at birth being still only about one-half of the adult normal depth.

In the case of the prefrontal region, though the results are not comparative, they are sufficient (especially when combined with other data, to which I shall refer later) to indicate that evolution is individually variable and occurs at a later date than is the case in either of the other two regions.

LAMINATION OF DIFFERENT REGIONS OF THE CORTEX.



I now propose to illustrate the lamination of the regions of the cortex which are under consideration, and in the case of the prefrontal area it is my intention, for reasons which I shall presently detail, to describe at some length its general structure. I would add that the micro-photographs I am about to exhibit are of different magnifications, as it is necessary that the whole depth of the cortex should be present.

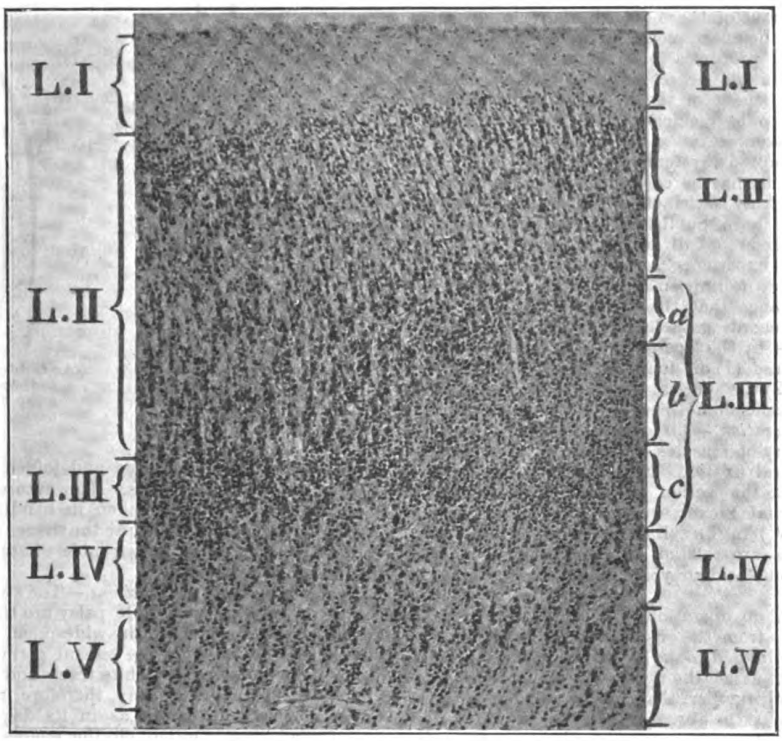
[The lamination of the visuo-sensory and visuo-psychic regions was then described and illustrated.] One of these illustrations, taken from a fœtus of 7 to 8 months, is shown in Fig. 10. On the right hand side is seen the periphery of the visuo-sensory region, in the middle the abrupt passage of this type of cortex into the surrounding visuo-psychic, and on the left hand side the cortex of the visuo-psychic zone. It will be seen that the line of Gennari suddenly ceases and the two layers of granules run into one, which occupies the site of the inner, the outer cell or pyramidal lamina at the same time increasing to almost double the depth. A comparison of this illustration with Fig. 5, which shows the prefrontal cortex of the same case, indicates that the last is in degree of development far behind the cortex of the visuo-sensory and visuo-psychic regions, which, particularly the former, much more closely resemble the adult type.

[The general fibre architecture of the cortex was then referred to, with the object of indicating that the horizontal fibre bands of the cortex bear no necessary relationship to the original laminæ from which the cortex has been evolved. Finally, the prefrontal cortex was referred to in greater detail in consequence of the fact that the great delicacy and high complexity of the structure of this region have been denied.]

It has been definitely stated by Campbell in his recent

FIG. 9.

The figure shows the mode of evolution of the cell laminæ of the cortex of the visuo-sensory, visuo-psychic, and prefrontal regions. The bottom series represents the inner cell or polymorphic lamina, the middle series the middle cell or granule lamina, and the upper series the outer cell or pyramidal lamina. A description is given in the text, but in general the figure suggests that the visuo-sensory cortex develops before the visuo-psychic, and this before the prefrontal; that the inner cell lamina develops before the middle and the middle before the outer; and, finally, that in the visuo-sensory and visuo-psychic regions the middle cell or granule lamina is the receptive lamina of the cortex and develops more rapidly than does the inner cell lamina of these regions.



monograph, which has attracted great attention, that the prefrontal cortex is of slight structural and functional significance. He remarks: "The structural development of the 'prefrontal' cortex is exceedingly low. It presents an extreme of fibre poverty. All the fibre elements are of delicate calibre, and its association system is particularly deficient. Its cell representation is on a similar scale. The cortex is also shallow." There is no mistake, as has been suggested, with regard to the region under consideration, as a comparison of the diagrams of Campbell and of Brodmann at once indicates; and I purpose showing that the cause of the great discrepancy in the descriptions lies in the difference of method adopted. Campbell used throughout his investigations the Wolters-Kulschitzky method, which

as ordinarily employed I regard as quite unreliable for this especial purpose. The method, on the other hand, which I adopt for the staining of the fibres of the cortex is based on the results of a research which I conducted many years ago into the chemistry of the Weigert-Pal method. I found that this process is not a specific method for the staining of medullated nerve fibres with hæmatoxylin, but is a method of dyeing fibrils which comprises three distinct operations—the mordanting of the fibrils, the formation of a lake in them by the employment of a basic dye, and, finally, the removal of the stain by oxidation from nearly every other part of the complex tissue under treatment. I compared the method with what would occur were a fabric composed of different fibres interspersed with fine glass threads, stained by a commercial process. The glass threads would refuse the mordant and consequently the lake, whereas the fibres would retain the stain. In the case of human tissue, the more highly metabolic elements represent the fibres, and the more fixed and lowly metabolic elements the glass threads. Further, the process is applicable to any, and not solely to nervous tissue—e.g., kidney, involuntary muscle, &c., form beautiful low-power specimens. The mordanting of the tissue is the most important process, and osmic acid, iron alum and ammonium molybdate, used separately or in succession, are the strongest mordants. My results were independently and almost simultaneously confirmed by Herrick, and the method has for years been successfully applied to the staining of cortical fibrils by G. A. Watson, who in 1903 published details of the special mode of employment necessary to display them, and of the difficulties which attend the obtaining of positive results. The usual Weigert-Pal methods, however, are still in general use, and by means of these it is practically impossible to stain even imperfectly the delicate fibrils of the prefrontal cortex.

[Photographs were then shown illustrating the special method referred to. The first series indicated the results of staining different types of fibre architecture of the nervous systems of the frog, dog, and cat. The second illustrated the minute structures of the prefrontal region. The specimens indicated the high complexity of the fibrillar meshwork throughout the grey matter, since, by means of high-power micro-photographs, the whole depth of the cortex was illustrated.]

In view of these photographs it is impossible to deny the great complexity of the fibre architecture of the prefrontal region, and I may add that John Turner in 1907, the year following the appearance of my paper on this subject, also combated the statements of Campbell and remarked that the prefrontal region, treated by a special method of his own, shows a wealth of intercellular fibres probably greater than in any other region of the cortex.

FIG. 10.

The cortex of a seven to eight months' fœtus. 94 diameters. The microphotograph is prepared at the periphery of the visuo-sensory area, and shows the passage of the visuo-sensory cortex into the visuo-psychic. L.I. to L.V. are as in the preceding illustrations; L.III.A and L.III.C are the two layers of granules; and L.III.B is the intermediate fibre layer or line of Gennari, of which three layers the middle cell lamina consists in the visuo-sensory area. In the centre of the illustration it will be noted that the line of Gennari, L.III.B, ceases, and that the layers of granules, L.III.A and L.III.C, run into one to form the granule lamina, L.III., of the visuo-psychic cortex. A comparison of this figure with Fig. 5, which illustrates the prefrontal cortex of the same case, very clearly demonstrates that the visual cortex of this case is much more advanced than that of the prefrontal region in its degree of development. These figures thus afford a partial graphic illustration of the truth that the visuo-sensory cortex develops before the visuo-psychic and the latter before the prefrontal.

THE INVALID CHILDREN'S AID ASSOCIATION.—The annual meeting of this association will be held, by kind permission of the Duchess of Marlborough, at Sunderland House, Curzon-street, London, W., on April 27th, at 3 o'clock. The Duchess of Marlborough will preside and the Bishop of Bath and Wells, Dr. Robert Hutchison, and Mr. D'Arcy Power will be among the speakers. Applications for tickets of admission may be made to the secretary, 69, Denison House, Vauxhall Bridge-road, Westminster, S.W.

ON THE FAILURE OF NERVE ANASTOMOSIS IN INFANTILE PALSY.

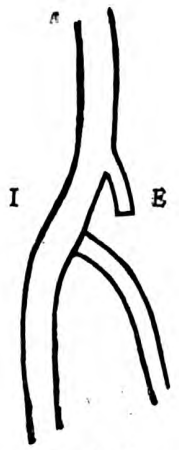
BY W. B. WARRINGTON, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN TO THE DAVID LEWIS NORTHERN HOSPITAL, LIVERPOOL;
AND
R. W. MURRAY, F.R.C.S. ENG.,
SURGEON TO THE HOSPITAL.

FOR the last three years or so we have been watching with much interest the progress of several patients for whom, in consequence of the crippling from anterior poliomyelitis, a nerve anastomosis was performed. The observations are on five patients, four of whom suffered from infantile palsy; in two the upper limb was affected, in two the lower. The fifth case was a traumatic lesion of the great sciatic nerve, due to a dislocation of the hip. We may say at once that in none of these cases has any improvement, the direct result of the anastomosis, resulted. Improvement due to the natural processes of repair in the cord was observed to a considerable degree, quite sufficient to satisfy the parents of the benefit of the operation, but, as will be obvious, in no wise to be connected with the actual surgical interference undertaken.

We have not attempted a systematic review of the literature on this subject, but it may be confidently asserted that very few instances of a truly satisfactory nerve anastomosis for infantile palsy have been published. The failure of this method, which looked so full of promise, is particularly disappointing. Our experience suggests that as successful cases are certainly few failures may be more numerous, and it is of some importance that those also should be recorded. We consider such records gain in value when recorded by a physician as well as by the operator. The cause of failure may be either because (1) an inappropriate time is chosen for the operation; (2) the surgical technique is at fault; or (3) physiological reasons do not permit of recovery.

1. *The time for operation.*—No one has insisted more upon the power of recovery of muscles under proper treatment—rest, massage, postural fixation—than Mr. Robert Jones, and we venture to refer to the section on Treatment in a paper on Palsies of the Brachial Plexus, written by that surgeon and one of us (W. B. W.) in THE LANCET of Dec. 15th, 1906, where several cases are related of great improvement in infantile palsy as long as two years after the onset of the disease.

We consider that no operation should be contemplated unless for six months from the onset of the disease assiduous treatment has been directed to the palsied muscles to improve their nutrition and to assist the return of power by adequate postural support, and, further, that at the end of this time faradic irritability must be absent, although a strong current is used whilst the patient is anæsthetised. The following case well illustrates this rule:—



A woman, aged 27 years, seen in private practice and so circumstanced that the best of nursing, medical attention, with constant intelligent coöperation of herself and husband was obtained, was seized in the early part of August, 1906, with poliomyelitis anterior acuta, causing widespread palsy of both limbs. It was not until the lapse of six months that the patient recovered power enough to walk, and at the end of that time the flexors of the forearms feebly responded to voluntary effort and to the faradic current. The deltoids were powerless and gave no trace of faradic excitability. A year later all the muscles except the deltoid, which remained completely powerless, had practically fully recovered.

Experience, we think, shows that it is the deltoid which, in all acute peripheral palsies of the upper arm, shows the least response to the methods of nature or art, and some means of restoring the power of abduction of the arm is urgently required—possibly the circumflex nerve may be anastomosed to another nerve. When a patient has not been under the most favoured circumstances adequate treatment should be adopted at least for three months before surgical interference is attempted. At the end of these periods of time we think that in cases of infantile palsy some degree of certainty as to the impossibility of future natural recovery may be obtained.

In passing, it may be remarked that in obstetrical palsy and in spontaneous neuritis the natural tendency to complete recovery is greater than in infantile palsy, and we think that amongst recorded cases of surgical treatment in the former group of cases are to be found instances in which the operation was superfluous. In the paper just mentioned by Mr. Robert Jones and one of us, of 6 cases of obstetrical palsy, 2 completely, 3 partially recovered, and of 4 cases of spontaneous neuritis, 3 completely recovered.

2. *The surgical technique.*—In every case the paralysed nerve was completely divided. In three cases the peripheral end of the nerve was engrafted into a longitudinal slit made in the sound nerve (Fig. 1). In two cases an end-to-end anastomosis was made. In one of these the divided external popliteal was joined to a flap raised from the sound internal popliteal nerve (Fig. 2); in the other case the spinal accessory

FIG. 1.

The external popliteal nerve E has been divided and grafted into a slit made in the internal popliteal nerve I.

FIG. 2.

An end-to-end anastomosis has been made by raising a flap from the healthy nerve.

nerve was completely severed and joined to the divided fifth cord of the brachial plexus. The suture material used was very fine silk. Care was taken in handling the nerves and in passing the sutures to bruise the tissues as little as possible. In no case was there any trouble whatever as regards the healing of the wound.

3. *Physiological considerations.*—The studies of Wichmann on the pathology of infantile palsy are the most valuable we have; they plainly show the widespread distribution of the lesion, that not only are the ventral cornual cells the site of disease, but also that the white tracts and pia mater are often affected. The final scar may, therefore, be most destructive, not so much in its extent as in its degree. Nevertheless, experimental work either on the effects of poisons on the nerve cells or on the results of various sections of peripheral fibres having origins in cells shows that the latter present a high degree of capacity for repair and that the *restitutio ad integram* may be complete. The clinical evidence that we are using a functioning nerve for the purpose of grafting is, of course, the presence of voluntary power and of faradic excitability in the muscles supplied by it. But the nature of the pathological lesion suggests that though these signs are present, yet even in the segment in the spinal cord, from which the functioning nerve takes origin, recovery may be incomplete. Hence one cause of the lack of success may be that the effort is too much; there may be sufficient nerve cells left to supply one group of muscles, but insufficient to supply two. If this be the explanation, it appears that the operation must often fail in its object, yet the very valuable observations of Kilvington[1] have shown that after section of a nerve trunk the axons branch, hence the peripheral supply at least may be increased.

Further, the state of the peripheral apparatus must be considered. Many are the battles which have been waged on the field of the facts and theories of nerve regeneration. We consider that the evidence of Langley and Anderson,[2] Head and Ham,[3] Mott, Halliburton, and Edmunds,[4] conclusively show that axons are alone reformed by downward

[2] Journal of Physiology, vol. xxxi., p. 418.
[3] Ibid., vol. xxxii.
[4] Ibid., vol. xxxi., p. 7.

growth from the centre, though a state of peripheral preparation occurs, as demonstrated by Ballance and Purves Stewart.[5] Until union with the central end is made the nerve remains in a resting stage, consisting of spindle-shaped fibres and elongated nuclei. For some time the isolated nerve remains susceptible, and axis cylinders growing from above find themselves in a responsive soil, but as time goes on the soil loses its virtue and the axis cylinders meet with greater and more resistance. Hence the contrast between the results of primary and secondary suture.

The intervals of time from the onset of the disease, in our cases, which had elapsed before anastomosis was performed were respectively 14, 8, 9, 6, and 8 months (see accompanying table). After such intervals secondary suture may, however, be, and often is, perfectly successful. It is difficult to believe that there can be any difference at given times in a stretch of nerves which has been kept completely separated from its central piece and a nerve whose cells of origin have been destroyed. Hence we must return to the state of the ventral cornual cells as an important factor in explaining the failure of nerve anastomosis in infantile palsy.

Although after section of a ventral root, or of a mixed nerve, the cells of origin suffer the well-known *reaction à distance*, yet Warrington[6] showed that after long periods of time all the cells had practically returned to the normal state. Far otherwise must it be in a segment of the cord which has passed through the storm of the violent disturbance constituting the pathology of infantile palsy. It will be remembered that Thorburn in his work on the Surgery of the Spinal Cord, whilst accepting the teaching of physiological experiment that a muscle derives its nerve-supply from several segments of the cord, yet demonstrates that clinically a muscle takes its main supply, its working power as it were, from one segment. When damaged this segment may so far recover as to carry out its own proper work, but it is unable to extend its sphere of action beyond its allotted task; there is no reserve to draw upon.

It may be that although we have failed to find any improvement in three years, yet that this time even is not long enough. Sherren[7] mentions a case of his of secondary suture of the brachial plexus in which voluntary power did not return for 182 weeks and faradic excitability for 333 weeks. So far, however, as we have gone, both clinical experience and physiological considerations lead us to give a very conservative opinion on the value of this method of treatment. We may mention that an additional case of failure to relieve an upper arm palsy was recorded by one of us and Robert Jones in THE LANCET in December, 1906. We do not, however, desire in the least to entirely condemn the operation; only in this method does there appear in many instances any hope for the patient. Perhaps we have hitherto been too ambitious; may it be that an attempt to restore the function of one muscle may be successful and the residual capacity of the spinal cord be sufficient to meet the smaller demand? Failure in this direction renders the immediate and early treatment in infantile palsy all the more urgent. If there be any means of limiting the range of destruction of the cord it must be employed and afterwards the muscles assiduously tended and guarded during their convalescence.

We now relate the essential clinical features in our cases.

CASE 1.—A.M. The illness began on Sept. 25th, 1906, with drowsiness, malaise, and fever, and four days later the patient was admitted to hospital. There was extensive paralysis of the left upper and both lower limbs, but it was found that under an anæsthetic faradic excitability was present in all the muscles of the left lower limb except the extensors of the foot, whilst in the right lower limb the quadriceps in addition failed to respond. The palsy of the left upper limb was more severe, slight flexion of the fingers and wrist alone being possible, nor except in these could any faradic excitability be obtained. The right upper limb was unaffected. Under treatment the lower limbs rapidly improved, so that in a month's time the patient could just stand with assistance. This improvement was maintained and the lower limbs made a practically complete recovery. No change occurred in the left upper limb. Mr. Murray operated on May 7th, 1907. The fifth cord of the brachial plexus was divided and joined end to end to the spinal accessory nerve.

Note on July 16th, 1908, reads: "Absolute loss of power in all the muscles of the left upper limb except the flexors of the fingers and hand; these react to faradism. No others can be stimulated."

CASE 2.—E. J., aged 2½ years. Was first seen in March, 1906. Infantile palsy in the right upper limb of two months' duration. She had almost complete loss of power, the arm hanging helplessly by the side. Could just feebly grasp the fingers of observer. Under treatment some improvement occurred in the forearm, but the shoulder girdle group remained powerless. Mr. Murray operated on Oct. 18th, 1906. The fifth cord of the brachial plexus was completely divided and engrafted into a longitudinal slit made into the sixth cord.

The child has been seen several times. On Sept. 3rd, 1908, note reads: "Grasp strong and all the forearm muscles act well. Shoulder girdle muscles, deltoid, biceps, brachialis anticus, and spinati paralysed, wasted, and without faradic excitability. The child is capable by a manœuvre of flexing the forearm. This is first pronated and then the extensors of the wrist flex the arm to some extent." On July 8th, 1909, note reads: "Condition remains the same."

CASE 3.—E. C., aged 4 years. Admitted to hospital on Oct. 21st, 1906. In May of this year she had rapidly become palsied in both lower limbs. On examination these presented the characteristic signs of infantile paralysis; the only apparent voluntary power was that of slight flexion of the thighs and of the right hamstring muscles. Electrical testing, however, showed a wider distribution of faradic excitability, the adductors of the thigh and the sural muscles reacting. The quadriceps extensor cruris, glutei, and extensors of the ankle did not give a reaction. The patient was carefully massaged, the feet supported by sand-bags, and the galvanic current employed. A month later signs of recovery were observable in the thigh muscles and the power of the calf muscles had increased. The extensors of the feet remained, however, absolutely powerless and inexcitable to strong faradism when the patient was anæsthetised. On Nov. 27th Mr. Murray operated. The external popliteal nerve was divided and engrafted into the internal nerve. (See Fig. 1.)

On July 16th, 1908, the child was seen again for the first time since leaving the hospital. The right limb showed considerable improvement; flexion of the thigh on the pelvis and of the foot on the ankle were fairly well performed; the leg could be slightly extended and the knee-jerk was present. The left limb had not altered much; there was more power in the flexors of the thigh and calf muscles. The extensors of the ankle gave not the least evidence of improvement. Electrical testing gave corresponding results.

The child has been seen several times since. Our last note on Oct. 15th, 1909, reads: "Improvement continues in the thigh muscles on the right side; practically no alteration in the left limb. No improvement in the condition of the extensors of the foot. The child walks with calipers and the mother is much pleased."

CASE 4.—W. C., aged 12 months. First seen on March 31st, 1907. Infantile palsy dating from the age of 7 months. It was found that the extensors of the right foot alone were paralysed and gave no response to the faradic current, the patient being anæsthetised. Mr. Murray operated in April, 1907. The external popliteal nerve was joined to a flap raised from the internal nerve. (See Fig. 2.)

The child was examined on several occasions, the latest being Oct. 15th, 1909. Our notes read: "The right foot is in the position of equino-varus, the thigh and calf muscles are well nourished, all movements of the thigh and flexion of the foot well performed. Knee-jerks present. No power and no faradic excitability in the extensors of the foot."

CASE 5.—F. B., aged 25 years. In October, 1905, severe injury, attended with loss of consciousness and dislocation of right hip-joint. On May 31st, 1906, there was complete paralysis of tibialis anticus, extensores hallucis et communis digitorum, with full R.D. (F. = 0, G. sluggish, A. > K., and both more excitable than on left side). Some weakness also in tibialis posticus and peroneus longus, but faradic irritability present. The calf muscles were normal. There was a small area of loss of epicritic sensation; deep pressure and protopathic sensation intact. It was supposed that the injury had damaged the external popliteal fibres in the trunk of the great sciatic, especially those making up the anterior tibial nerve, whilst the fibres for the musculo-cutaneous had largely escaped; the loss of epicritic sensation was, however, due to lesion of these fibres. On June 26th, the popliteal space was exposed. The sciatic nerve was seen to be formed by two nerve trunks very different from each other. The external popliteal part was thin, bluish looking, and softer than the internal popliteal part. The external popliteal nerve was cut across in the upper part of the

Data from the Cases Related Above shown in Tabular Form.
(No improvement found in any instance.)

popliteal space and prepared so that it was placed in an incision made into the internal popliteal nerve. This incision was first longitudinal and then the fibres divided transversely to some depth in the substance of the nerve. The note on Oct. 4th, 1906, says that no recovery in the anterior tibial nerves had taken place. The tibial posticus had fully recovered.

When last seen on April 15th, 1908, no change had occurred.

Note.—Since the above was written a case lost for some years has been found. H. J., aged 13 years. Both lower limbs paralysed since infancy. The muscles supplied by the anterior crural nerve are those chiefly affected. She was first seen in 1905, and was then 8 years old. She was wearing a Thomas's knee-splint in which she could stand, but was unable to walk. The right limb was the weaker of the two. On Jan. 17th, 1905, Mr. Murray joined the anterior branch of the right obturator nerve to the nerve supplying the rectus muscle, end to end. It is five years since the operation, *and though there is no improvement as a direct result of the anastomosis*, still, strange to say, the child can now walk, with the assistance of a splint, a distance of 3 miles.

AN ANATOMICAL INQUIRY INTO THE PATHWAY OF TUBERCULAR INFECTION.

BY FREDERIC WOOD JONES, M.B. LOND.,
LECTURER IN ANATOMY IN THE UNIVERSITY OF MANCHESTER.

THE fact that tuberculosis is prone to attack certain definite places in the body has often tempted anatomists to discuss the possibility that some structural peculiarity may favour the commoner forms of infection, and to speculate upon the route by which the infection reached its sites of election. Since the distribution of the disease has such a well-defined anatomical localisation, it is, perhaps, not unnatural that explanations should have been attempted, based upon the purely anatomical considerations, as to how these sites became invaded and why they are selected by the bacteria for their primary foci in the invasion of the body.

Such hypotheses as have been put forward by anatomists hitherto have not carried conviction, for they have been the outcome of attempts to devise a route for the bacillus upon the supposition that it entered the body with the inhaled air or by means of the blood stream. This is my primary reason for rejecting the explanations previously suggested by anatomists, but it is not the only one. Even supposing it were known for certain that the tubercle bacilli most commonly invade the body by the inhaled air or by the blood stream, the suggestions usually advanced to explain why it is that certain spots are peculiarly exposed to attack, while the rest of the body remains comparatively immune, are wholly unconvincing. Why tubercle attacks the apex of the lung does not seem to be explained by the inquiries into the relative degree of expansion of different parts of the lung, or by the investigation of the action of the bronchial cilia. Why tubercle not uncommonly attacks the base of the lung and the abdominal cavity in children, and why it has a selective action in its attack upon the various regions of the vertebral column in cases of caries of the spine, are other problems not solved by any inquiry into the relative expansibility of different parts of the lungs or the movements of the thoracic walls.

So far as I am aware, no anatomical explanation of the incidence of tubercular disease has yet been attempted in the light of the new knowledge which recent research has afforded of the mode of invasion effected by the tubercle bacilli. The work of Calmette and Guerin, of Vansteenberghe, Grysez, and Ravenal, and of Symmers and Whitla has shown, beyond all dispute, that there is a route for invasion provided for the bacillus by way of the alimentary canal. The experiments that have been performed upon animals to demonstrate this have proved, beyond all manner of doubt, that tubercle bacilli may reach the lungs from the lumen of the alimentary canal without leaving any trace of their passage through its walls. How far this route may be regarded as the normal one for the invasion of the human body is a question for the investigations of pathologists and clinicians to solve; but the certain knowledge that the tubercle bacillus can reach the lungs *viâ* the alimentary canal opens up a new field for the anatomist, and prompts an attempt to map out a pathway of infection. The common belief that nothing remains to be discovered in the gross anatomy of the human body is being refuted every day in the dissecting-room; nor is this field of investigation likely to become exhausted so long as pathology, medicine, and surgery are constantly adding new facts and new problems, the explanation or solution of which depends in any way upon the anatomical disposition of the parts of the body. The reinvestigation of the anatomy of the chest is not likely to yield barren results when a fact so fundamental as the possibility of the alimentary route of tubercle bacilli to the lungs is established beyond all doubt. Regarding these facts from a purely anatomical aspect, I have attempted to determine (*a*) a possible pathway for tubercular infection; (*b*) to show it to be a probable one; and (*c*) to demonstrate that, even though this investigation is in its initial stages, this route has been found to have been actually used for conveying infection to the apex of the lung in a case of pulmonary tuberculosis. I publish the facts that I have determined merely as a suggestion of the possibility of this route and as an appeal to those who have opportunities for a fuller investigation of the problems raised than is possible within the walls of the dissecting-room, to provide the data for the study of the anatomical distribution of tuberculous lesions.

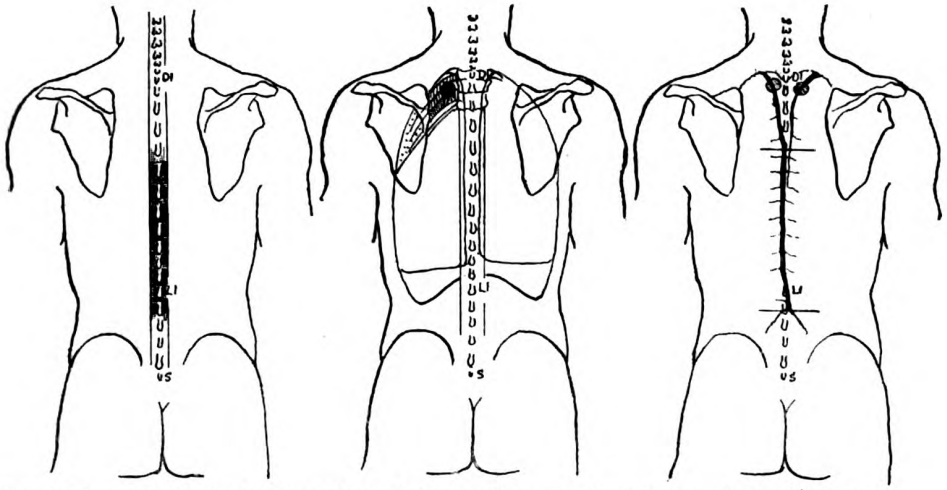
The problems which forced themselves upon me in the course of my demonstrations on the anatomy of the chest were these: Why does spinal caries so commonly manifest itself in the lower and mid-dorsal regions; and why does phthisis, in the adult, so constantly show itself first above this level, and so very frequently in one definite spot? As to which is the actual vertebral body most commonly found to show the first signs of spinal caries there is not complete agreement, but that the region from the sixth dorsal vertebra to the second lumbar is the part of the spine within the limits of which the process starts appears to be generally accepted (Billroth, Hueter, Holmes, and others). (See Fig. 1.) Tubby gives the site of election as "the lower dorsal region or the junction of the dorsal and lumbar regions," and Adami says that "in tuberculosis of the vertebræ those from the seventh dorsal to the second lumbar are the ones usually involved."

With regard to apical phthisis, the site of election is universally agreed upon, and a spot "from one to two inches below the extreme apices" (Percy Kidd) seems to be the site where the disease is most usually detected. (See Fig. 2). Other problems also present themselves: Why, in children, does tubercular disease so commonly manifest itself as abdominal, or generalised tuberculosis; and why, when it attacks the lungs in children, is it not at all uncommon for it to start as a basal phthisis?

The consideration of these problems, and the facts determined by Whitla, Symmers, and others, demands a search for some structure, or system of structures, which might carry the infection from the alimentary canal to these parts, and which has, at the same time, an intimate anatomical relation to them; moreover, it must be a system which, at varying periods of life, shows such changes as would be likely to alter the route of infection.

The absorbent system, so far at least as we understand its plan, fulfils all these conditions. The relations of the lymphatics of the posterior mediastinum—the thoracic duct and right lymphatic duct—when compared with the common sites of tubercular disease, assume a new and startling significance; for, unless it is merely a striking coincidence, the facts point clearly to these lymphatics as the pathway of infection in pulmonary and spinal tuberculosis. The thoracic duct is most intimately related to the spinal column from the sixth dorsal vertebra to the second lumbar vertebra—i.e., *precisely those vertebræ, the bodies of which are most subject to tubercular infection.* (See Fig. 3.) The position of the first appearances of caries upon the bodies of the vertebræ is highly suggestive of an infection from some structure lying upon the front of the centra; and in addition is the fact that caries at times "commences from many centres, often situated on different vertebræ, and unconnected with each other" (Erichsen). The structure most intimately related to the lungs at the site of election of phthisis is the lymphatic channel passing upwards and forwards over the pleura to join the subclavian veins. In this situation the thoracic duct (or the right lymphatic duct) lies directly upon the pleura, and in more intimate anatomical relation to it than

FIG. 1. FIG 2. FIG. 3.



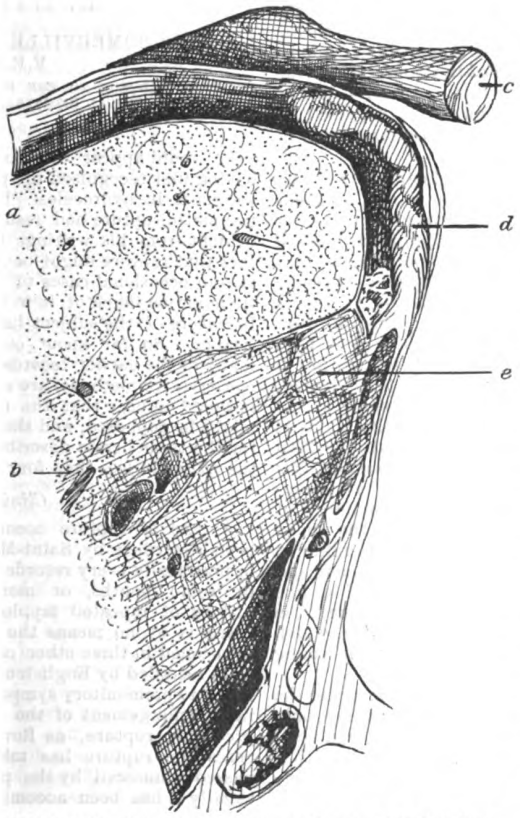


FIG. 1.—The posterior aspect of the trunk to show the site of election of tubercular disease in cases of caries of the spine.

FIG. 2.—The posterior aspect of the trunk to show the site of election of tubercular disease in cases of pulmonary phthisis. (After Percy Kidd. Allbutt's and Rolleston's "System of Medicine.") The area is indicated on the left side only, but it must be remembered that the corresponding region on the right side (see Fig. 3) is attacked at least as often, and according to many authors even more frequently—possibly because the smaller right duct is more liable to occlusion than the left.

FIG. 3.—The posterior aspect of the trunk to show the position of the thoracic and right lymphatic ducts, and the coincidence of their situation with that of the sites of election of tubercular disease shown in Fig. 1 and Fig. 2.

any other structure in the thorax or neck. So intimate is this relation that the easiest way to find the ducts is to remove the lung from the pleural cavity, and then to look for them through the pleura at the site of election of phthisis. The right lymphatic duct is a larger channel than is at times supposed, and it carries all the lymph from the right side of the diaphragm (and probably the liver) and from the right side of the thorax. More than this, it is reinforced by channels crossing the vertebral column from the left duct. The existence of these channels was clearly shown by the mercurial injections made by anatomists of a former generation, and by studying the effects of a stoppage of the lymph flow in the (left) thoracic duct: (*a*) experimentally, by ligature; (*b*) pathologically; or (*c*) experimentally, by tying all the veins into which its contents might be poured. When a surgeon cuts the thoracic duct and ligatures it the patient may exhibit no ill effects; but this is not necessarily due to the fact that the openings of the left duct are multiple, for the far older experiments of the Hunterian epoch showed that the left duct and all its openings could be ligatured, and yet the lymph-return persist unimpaired. Another constituent of the lymph channels which run forwards over the pleura is the series of vessels from the œsophagus itself, and their relation to the apex of the lung is also intimate. So much for the anatomical possibility that tubercle bacilli could find a ready path to their sites of election by the thoracic ducts. It remains to inquire if there is any evidence that tuberculosis of the thoracic duct occurs, and if possibly it might be the primary seat of disease in the body.

FIG. 4.

Sketch of the dome of the pleura and apex of the left lung from a case of phthisis. The specimen is seen from behind and the lung is shown in section. The tubercular disease is seen to have its apparent origin at the point of adhesion of the diseased thoracic duct, where the pulmonary affection is most intense and from which the disease has obviously spread. *a*, Area of lung at extreme apex, practically normal. *b*, Area of lung showing disease, but less advanced than in pleural area. *c*, First rib. *d*, Diseased thoracic duct seen through pleura but cut obliquely at the pointing-line *c*. *e*, Maximum intensity of disease of lung at the point of adhesion of diseased duct.

In 1790 Cruickshank ("Anatomy of the Absorbing Vessels") mentions that "Mr. Cheston of Gloucester, some years ago" showed him a thoracic duct that was blocked by a solid substance. In 1789 Astley Cooper went fully into the question. In 1827 Gendrin turned his attention to disease of the duct, and in 1882 Stilling carried on the investigations begun by Ponfick and described tuberculosis of the thoracic duct minutely. He described tubercles and tuberculous ulcers of the lumen of the duct "especially on the valves"; and he met with this condition in 5 among 18 subjects dead of "acute tuberculosis," and he adds that it is mostly found in "elderly people." In an editorial comment on this work in THE LANCET of June 10th, 1882, it is said that "old handbooks of medicine often allude to the occlusion of the duct by caseous material, and to its inflammation." It may therefore be said that tuberculosis of the thoracic duct is certainly a definitely established condition, and that it is associated with tuberculosis in other parts of the body; but I do not know of any evidence to show that it has been considered as primary, or as anything other than a pathological curiosity.

It is a condition that would be very easily overlooked in the ordinary routine of post-mortem examination, for the tearing away of the apex of the lung from the dome of the pleura, and merely noting the adhesions broken down in the process, would certainly prevent its recognition, even if the disease were well established. As the result of the examination of a case of apical phthisis, which I have dissected in the anatomical department here, it is possible to go a stage further, and to state that the tubercular disease in the lung appeared to have its seat of origin precisely at the point of contact of a diseased thoracic duct. In this case the limitation of the disease, the firm adhesion of diseased lung, diseased pleura, and diseased duct were most suggestive of an invasion of the lung from a primarily infected duct. (See Fig. 4.) From such an isolated case it is unsafe to assume more than that apical phthisis *may* be associated with tuberculosis of the thoracic duct, and have its seat of maximum intensity at the point where the diseased duct is adherent. If such a mode of infection of the lung is in any way common it would bear out the oft-repeated observation that an attack of pleurisy is often the first premonitory symptom of phthisis. That the pleurisy is not primary in such cases is the general opinion, yet Adami states that, "exceptionally, tuberculosis of the pleura is met with as a primary lesion, without discoverable disease elsewhere" ("Principles of Pathology," p. 330). The association needs to be sought for more widely, and early cases require careful investigation. If the suggestion of the causal relationship of tubercular disease of the thoracic (or right lymphatic) duct and phthisis, as put forward here, should prove to be unfounded, it must be considered an extraordinary coincidence that in the only case of early phthisis that I have had an opportunity of examining since the possibility of this mode of infection was suggested to me by purely anatomical considerations a tubercular thoracic duct should have been found secondarily adhering to the pleura and lung, and so infecting them. (Fig. 4.) In the cases of caries of the spine which come to post-mortem examination it would be of the greatest interest to know the condition of the thoracic duct. An early case of Pott's disease, if carefully dissected, might be expected to furnish some evidence of disease in the structures lying in contact with the diseased bone.

The question of the different sites of election for tubercular disease at different periods of life is one of great interest and one which would probably receive a readier explanation were our knowledge of the lymphatic system more complete. The older anatomists knew well that with advancing age the lymphatic system became increasingly difficult to inject, and that there was a closing down of the system in adult life; Ruysch went so far as to assert that the lymphatic glands, and with them the lymphatics, disappeared from the mesentery in old people. Cruickshank declared that "it cannot be denied, the glands of the mesentery are exceedingly small in old people"; but he cites Haller as having seen the thoracic duct full of chyle "in those who had passed the 70th year of their age." In the case of other mammals our knowledge is more complete. The experiments of Vansteenberghe and Grysez demonstrated that while particles of China ink, absorbed from the stomach, reached the lungs of adult guinea-pigs, they were filtered off by, and retained in, the mesenteric glands of young animals. Symmers and Whitla repeated these experiments and obtained a like result, but they add, "the carbon had also reached the thorax through the lymph channels of the diaphragm, which was rendered jet black throughout its substance" in young guinea-pigs.

In the absence of more definite knowledge concerning the age changes of the human lymphatic system these facts are only to be regarded as suggestive; but so far as they are capable of being interpreted they would appear to point to the fact that with increasing age the abdominal lymphatics become more constricted, and the lymph circulation becomes more centred on the thoracic ducts. If some such process did in fact take place, it would offer a ready explanation for the different sites of tuberculous infection in childhood and in adult life. If the mesenteric lymphatics most readily carry China ink (and tubercle bacilli) in children, the advent of tuberculous peritonitis is not difficult of explanation; and if the lymphatics of the diaphragm readily carry infection to the thorax in children, then basal phthisis is easily explained.

Evidence of some such change would appear to be seen in the waning of lymphoid structures when the processes of growth have been carried out; for in the adult an atrophy of lymphoid tissues, and probably of lymph channels, takes place. At the period of life when bodily growth is complete it is not impossible that, with the atrophy of lymphatic structures, the lymph stream becomes more dependent upon the thoracic ducts; and this is the time of life when apical phthisis is most prone to occur. If the route of the thoracic duct should chance to be that by which the tubercle bacilli reach the lung in phthisis, and the spine in Pott's disease, it becomes a matter of importance to see if there is any symptom that might seem to point to an involvement of the duct. Of primary disease of the duct nothing appears to be known. "It is, as a rule, quite impossible to determine during life that the thoracic duct is diseased. This might be suspected if, along with some other known cause which might lead to obstruction of the tube, the patient became extremely emaciated, anæmic, and weak, without other obvious reason to account for the symptoms" (Roberts). These symptoms are well marked in phthisis, even in early cases, and adequate causes to account for them are not usually apparent. "The explanation of the wasting is not always obvious. There is often loss of appetite, and especially distaste for fat in every form" (Fagge and Pye-Smith). Such symptoms—and especially the peculiar distaste for fat—are suggestive of the possibility that the duct is involved as the primary seat of the disease.

ON RUPTURE OF THE TUNICA VAGINALIS IN HYDROCELES.[1]

BY SOMERVILLE HASTINGS, M.S. LOND., F.R.C.S. ENG.,

ASSISTANT SURGEON TO THE EAST LONDON HOSPITAL FOR CHILDREN LATE SURGICAL REGISTRAR TO THE MIDDLESEX HOSPITAL.

IT would appear that to Bertrandi is due the honour of having first recognised the possibility of rupture of the tunica vaginalis in hydroceles. Pott also described a case where traumatic rupture had resulted in spontaneous cure, and it is evident from his writings that Hunter fully recognised the fact that rupture might occur. But except for the publication of occasional cases of this accident there has been but little notice taken of it in England or Germany, most of the literature of the subject being derived from Switzerland and France. So far about 50 cases have been recorded, but many of the earlier records, particularly of those treated by conservative methods, are exceedingly scanty. Nevertheless, it would appear that the condition can hardly be as rare as might be supposed, and that not a few cases pass unnoticed, for the three herein described have come under the notice of the writer in less than four years at a single hospital.

Clinical History.

A case of rupture occurring in an acute hydrocele has been described by Saint-Martin; but, with this exception, in practically every recorded case the hydrocele had existed for some months, or more often for several years. The history of repeated tappings given in the first two of my cases is by no means the rule, and I have only found it mentioned in three other cases, all of which, strange to say, were recorded by English observers. As a rule, there appear to be no premonitory symptoms, nor is there at all frequently rapid enlargement of the hydrocele during the few weeks preceding rupture, as Reverdin thought. In one or two cases the rupture has taken place during sleep, or has passed unnoticed by the patient, as in my second case, but usually it has been accompanied by a feeling of something tearing or giving way. Pain is a much more variable symptom, for while usually severe and described as stabbing or cutting, it is occasionally entirely absent at first. The pain, when present, lasts a variable time and is but rarely accompanied by faintness or any general symptoms; indeed, in not a few cases the patient has gone on with his work a

[1] A paper read before the Surgical Section of the Royal Society of Medicine on March 8th, 1910.

few minutes after the occurrence of the rupture and only sought medical advice after some hours on account of continuous or increasing discomfort.

The immediate effect of the rupture noticed by the patient is usually that the swelling of his scrotum has become larger and softer, and an examination during the first 12 hours generally reveals a more or less uniform œdema, absolutely confined to the affected side of the scrotum, which appears to have been translucent in most of the cases in which this point was investigated. The position of the testicle can generally be made out by palpation at this stage. After the first few hours the œdema slowly spreads to the penis, especially the prepuce, the opposite side of the scrotum, and even at times to the lower part of the anterior abdominal wall and perineum. More or less discolouration of the scrotal tissues from effused blood is generally to be seen within 12 or 24 hours of the rupture, and where a vessel of any size has been torn a subserous or subcutaneous hæmatoma will be produced. The scrotum is usually very tender when touched, and there is sometimes a recrudescence of the pain, which lasts two or three days and may be so severe as to compel the patient to keep his bed. Bailly regards the persistence or recurrence of pain as a sure sign of the formation of a hæmatocele and the consequent necessity of operative interference.

If untreated, the œdema generally begins to subside after a few days, and has usually entirely disappeared in a fortnight or three weeks, while the hydrocele, which has either become much smaller or has disappeared altogether, in most cases slowly refills. It is probable that cases such as those described by Velpeau, in which the patient goes to bed with a well-marked hydrocele and wakes up next morning without any scrotal swelling at all, are to be explained by rupture without hæmorrhage and rapid absorption of the effused fluid. In a few cases after rupture a soft area has been noted in some part of the scrotum, in the base of which an opening admitting one or two fingers could be felt through the skin. The absorption of the fluid is usually accompanied by slight fever and general malaise, and occasionally a feeling of sickness. In a few cases polyuria and even diarrhœa have been noted. Complications are extremely rare, but cases of gangrene and even fatal septicæmia have been reported.

Pathology.

In considering the pathology of this affection one has first of all to inquire *why* the tunica vaginalis ruptures. In most of the recorded cases the traumatism producing the rupture, if present at all, has been of a quite insignificant character, while we know that the normal tunica vaginalis is a membrane of some strength and capable of resisting considerable fluid pressure. This is shown by the experiments of Saint-Martin and Delore. The former observer, by injecting fluid under pressure into the tunica vaginalis of post-mortem subjects, found that one atmosphere was the least pressure under which he ever obtained rupture, while in 7 cases out of 14 he failed to obtain rupture at all. In each of the seven cases in which rupture occurred it was situated in the upper part of the tunica vaginalis. Delore, however, found the rupture almost as frequent below as above. When a hydrocele has formed, the tunica vaginalis has still considerable strength, and Mauclaire and Vinsonneau state that they have tried to produce rupture by pressure on the hydroceles of patients under chloroform, immediately before performing radical cure, but have failed. It seems clear, therefore, that, except under the influence of relatively severe traumatism, to undergo rupture the tunica vaginalis must be in some way changed. In what exactly this change consists there is some difference of opinion, but before mentioning the two principal views on the subject it will be convenient to allude briefly to the anatomy of the part.

As is well known, the parietal portion of the tunica vaginalis is covered by several layers of tissue. Beneath the skin is the dartos, a thin, reddish membrane of unstriped muscular and elastic fibres, consisting, according to Barrois, of two separate layers, the outer surrounding both testicles, the inner and stronger forming a separate investment for each. In the middle line there exists a potential space, bounded on each side by the deep layer of dartos, and into this space pathological effusions occasionally take place. Next comes a thin layer of loose cellular tissue, called by the French the fascia of Cooper. On injecting fluid into the potential space formed by this loose tissue, it is found to be completely closed on the side of the thigh, but to communicate freely with the subcutaneous tissue of the perineum, penis, and anterior abdominal wall. Here pathological effusions collect much more frequently. Beneath this, again, is a strong fibro-muscular tunic, consisting of three layers more or less easily separable. It may be regarded as a fibro-muscular bag enclosing the testicle and cord, open only at the level of the internal abdominal ring. The lower portion enclosing the testis is by far the stronger. Separating the tunica vaginalis from this fibro-muscular coat is a layer of subperitoneal cellular tissue, in which blood-vessels, mainly branches of the funicular artery, ramify. This tissue is much better developed above than below; indeed, in its lower fourth the tunica vaginalis becomes firmly united to the fibro-muscular layer. Pathological effusions are frequent in this situation. According to Béraud, the tunica vaginalis often presents finger-like diverticula, one or two centimetres long, which end blindly sometimes after piercing the fibro-muscular tunic. While they may exist in any part of the tunica vaginalis they are said to be most common above. Although their existence is not admitted by all anatomists, they are regarded by Saint-Martin as the essential cause of rupture in hydroceles. Burdet and Delore, on the contrary, think that the cause should rather be sought in the softening and degeneration of the tunica vaginalis and its coverings. In comparing these two theories it will be well to inquire into the usual seat of rupture and the condition of the tunica vaginalis found at operation.

Saint-Martin, writing in 1883, stated that according to his observations the rupture most commonly took place in the antero-superior part of the tunica vaginalis. Reverdin, writing in the same year, regarded the anterior and central region as the most common seat. Since this time many cases have been recorded, and as a large percentage of these have been subjected to operative interference the exact locality of the rupture has been determined with much greater exactitude than formerly, and has been shown to have been situated at almost all points in the tunica vaginalis in different cases. From an examination of the records of a number of cases it would seem that the rupture is slightly more frequent on the anterior aspect than on the posterior, a fact perhaps explained by the adhesion of the tunica vaginalis posteriorly to the scrotum noted several times. Some French authors seem to regard the point of application of the traumatism in traumatic cases as important in determining the situation of the rupture, but it would appear contrary to the laws of fluid pressure to expect this. We must conclude that the tunica vaginalis ruptures at its weakest point, which may be anywhere, and by no means exclusively in the juxta-funicular portion, as Saint-Martin thought.

In the second place, what is the condition of the tunica vaginalis? In nearly every case in which the tunica vaginalis has been carefully examined it has been found diseased. The membrane itself is usually thickened and vascular, and may present on its inner aspect flattened plaques of a yellowish colour, resembling those of atheroma, and sometimes calcified or even ossified. In the substance of the membrane may be areas of fatty degeneration, and occasionally false membranes are found on its inner surface. Histological examination of sections of the thickened tunica vaginalis after rupture have shown it to be composed of fibrous connective tissue, so thick and dense as to be completely deprived of cellular elements. Reverdin, who describes two cases of comparatively short duration before rupture, notes that even in these there were lesions in the tunica vaginalis, which no one would have expected, and the conditions found at operation in my third case are entirely in accordance with this observation. No doubt where the applied traumatism is sufficiently severe, rupture may occasionally occur in tunicæ vaginales that are but little changed, and it seems probable that the cases recorded by Stitelet were mainly of this nature. Even in these cases, however, a "washed out" appearance of the tunica vaginalis is described. Thickening of the fibro-muscular covering has also been noted in a few cases, but whatever changes may take place in the tunica vaginalis and the subjacent fibrous tunic the two membranes are always easily separable from one another.

It would appear, therefore, that the tunica vaginalis gives

way because it is diseased, and that the rupture may occur at any point on its surface.

We must next inquire what it is that gives way when a rupture occurs. Is it the tunica vaginalis only, or does the fibrous layer rupture at the same time also? Reverdin was of opinion that both coats generally gave way, but Burdet considered that it was the tunica vaginalis only which usually ruptured. Delore's experiments, in which fluid under pressure was injected into the vaginal sac, seem rather to favour the latter view, for in one case only out of nine was the fibrous layer ruptured; but little reliance can be placed on the results of these experiments, since healthy tissues only were involved in them. Certainly, in some of the more recent and carefully described cases, it is the tunica vaginalis only which has given way, but there can be no doubt that both varieties occur, so that the effusion of the serous fluid and blood may take place either into the subserous tissue, or into the loose cellular tissue immediately beneath the dartos, or into both.

Poncet of Lyons thinks it is possible to distinguish clinically between these two varieties. He says that a rapidly spreading œdema, with considerable ecchymosis extending on to the abdominal wall, indicates a rupture of the fibrous tunic, while a limited swelling, accompanied by slight ecchymosis, will be in favour of a rupture of the tunica vaginalis only. This will be more certain if the effusion is prolonged along the cord and forms a tumour of some size. In ten days or a fortnight after the rupture the greater part of the effused fluid will have been absorbed, and if there has been much bleeding it is then quite easy to distinguish a vaginal from an extra-vaginal hæmatocele, for the former surrounds and obscures the testicle, while the latter forms a swelling to one or other side of it. When the scrotal skin is adherent to the tumour it is strong evidence that the hæmatocele is situated external to the fibro-muscular coat. The hæmatocele thus formed may occasionally be absorbed, but it is much more usual for the scrotal tissues to become thickened around and for the swelling to persist indefinitely. Sometimes, in cases of repeated rupture without much hæmorrhage, an intra-parietal pocket is formed, which remains connected with the cavity of the hydrocele or may be gradually separated from it.

The rupture itself is usually slit-like, with sharp-cut or jagged edges. As in the cases here described, it is often longer than one would have anticipated. The fluid found on operation in the sac of the hydrocele is usually blood-stained and contains a variable amount of blood clot. The pouches resulting from the rupture are also filled with clot. The older French observers attributed the hæmorrhage to rupture of vessels in the cellular tissue, resulting from excessive traction as this tissue became distended with effused hydrocele fluid. This may be true in part, but there can be no doubt that blood is also derived from the vessels divided by the rupture of the tunica vaginalis or fibrous coat, the latter being often very vascular. Walther describes a case in which, on the evacuation of the clots, a profuse discharge of blood poured out from an artery in the torn edge of the tunica vaginalis. When the case is left to nature the tear in the tunica vaginalis, as a rule, slowly heals by the formation of a fibrous scar and the hydrocele refills.

Causes.

The exciting causes of rupture may be traumatism, as by a knock or blow, which presses the distended tunica vaginalis against the pubes, or pressure, as when the hydrocele becomes squeezed between the thighs by the contraction of the adductor muscles. There is also considerable evidence to show that muscular effort, such as occurs during a fall, a cough, defæcation, or a fit of anger, may produce the same effect. While Kocher would deny the possibility of this, Le Dran maintains it strongly. He believes that either by direct action of the lower fibres of the internal oblique on the vessels of the cord, or by increased intra-abdominal pressure, the tension in the blood-vessels of the tunica vaginalis is raised to such an extent that they give way, and the consequent increase of fluid in the tunica vaginalis is sufficient to determine its rupture. Baseil, on the other hand, believes the contraction of the cremaster to be the chief causative factor in these cases. But, besides these, so-called spontaneous cases undoubtedly occur, where rupture takes place without any apparent cause. In Velpeau's case a rupture occurred while the patient was asleep, and in a still more curious case described by Reverdin the patient felt a sharp pain, followed by all the symptoms of rupture, while seated quietly in a chair. The existence of spontaneous cases is of great interest and points strongly to some degenerative condition of the wall of the sac as the essential cause of rupture. In a few cases of this nature a rapid increase in the size of swelling has been noticed before the rupture, but this is, however, rare. It is probable that muscular effort is the commonest exciting cause, and that spontaneous ruptures are the rarest; but it is necessary to remember that most of the recorded cases occurred in hospital patients, who, for the most part, work hard, and are, therefore, most subject to traumatism and muscular strain. If, as seems probable, the true cause of rupture is degeneration of the wall of the hydrocele, in the absence of traumatism this degeneration may advance so far that rupture occurs after very slight violence or even spontaneously.

Diagnosis.

There is usually but little difficulty in recognising this condition if a reliable history is obtainable. It seemed obvious from the first in my three cases. Elephantiasis scroti and extravasation of urine are said to be the conditions for which it has been mistaken, and its resemblance to the latter is certainly close at first sight. Where rupture of the tunica vaginalis occurs alone, and there is but little scrotal effusion, the condition may closely resemble a hæmatocele; indeed, some think that not a few cases diagnosed as vaginal or parietal hæmatoceles arise in this manner. It is also necessary to remember that a vaginal hæmatocele may itself rupture, and in the absence of a reliable history and of translucency after the accident the two conditions will be very difficult to distinguish. When the rupture comes on acutely with fever and sickness, a strangulated hernia may be closely simulated. But the freedom of the hernial rings will at once make the diagnosis clear. Erysipelas will also have to be considered in such cases, but we must recollect that erysipelas may occasionally occur as a complication of rupture.

Treatment.

The first recorded case of ruptured hydrocele was published in 1757, and for many years very little in the way of treatment was recommended. But palliative measures rarely result in a permanent cure, as is seen by the records of several cases; for example, a patient of Serre, who repeatedly ruptured his own hydrocele by pressure when it became uncomfortably large, thereby obtaining temporary relief. Only two or three cases of cure without operation have been recorded years after rupture, nor should we anticipate that a simple rupture of a diseased organ would make it healthy. Injection of coagulants is likewise uncertain. While it has sufficed to cure in some cases, it has been followed by suppuration and sloughing in others. Where antiseptic precautions can be taken, the best treatment in most cases is to cut down on the hydrocele and perform a radical cure, clearing out all the blood clot and removing the greater part of the parietal portion of the tunica vaginalis. Where, as sometimes happens, firm adhesions exist posteriorly, binding the tunica vaginalis to the scrotum, it is probably best to follow Reverdin's advice, and leave this area untouched. In old men, too, where the testicle has ceased to be a functional organ, castration may be the simpler course. The only question is as to the best time to operate. When the œdema and infiltration are considerable, as in ruptures beneath the dartos, Poncet of Lyons recommends waiting a few days or a week, till most of the fluid is absorbed. He says the danger of suppuration, which is so liable to occur with large effusions of serum and blood, is thereby lessened. But where there is great pain from distension, something must be done to relieve the patient, and Bailly suggests that aseptic puncture of the hæmatocele is desirable as a temporary measure. With limited effusions there can be no reason to postpone operation.

In conclusion, I should like to thank Mr. J. Bland-Sutton for permission to publish the following cases, upon which, as well as upon those referred to in the subsequent bibliography, the paper is based.

CASE 1.—A man, aged 52 years, a painter, had suffered from a hydrocele of the left tunica vaginalis for five years. During this time he had been accustomed to have it tapped about every six months, the last occasion being in May, 1905. As more than the usual time between the tappings had elapsed, and as the hydrocele, though painless, gave trouble through its size and weight, he had determined on the morrow to seek relief. On March 9th, 1906, at about 10.30 A.M., the man, who

was out of work at the time, was walking down Charing Cross-road, and, seeing a sixpence, bent down quickly to pick it up. In doing this he is quite sure that he did not knock his hydrocele, but he thinks that possibly he may have pressed on it as he stooped down. He immediately experienced a sensation of something tearing or giving way, and felt a sharp pain in the left side of his scrotum. He felt rather giddy for a few minutes, but as soon as he recovered he felt for his hydrocele, which before had been smooth, firm, elongated from above down, and confined to the left side of his scrotum, and noticed that it had become quite soft. He walked about for a time; but as the pain, which had never left him since the accident, increased in severity, and as he began to feel generally ill, he came to the Middlesex Hospital at about a quarter to 12.

When seen in the out-patient room about 2.30 P.M. his condition was as follows. The left side of the scrotum was swollen to the size of a large orange. There was considerable superficial œdema, so that the skin appeared irregular on the surface, like the skin of an orange, and pitted readily. The œdema was entirely confined to the left side of the scrotum, and there was no discolouration or sign of effused blood anywhere. The whole scrotum was soft, and although on account of the tenderness the outline of the left testis could not be made out, it was quite evident that the scrotum contained no tense swelling of any appreciable size. Over the left external abdominal ring was a pad of fat. The penis was quite normal.

The next day slightly increased swelling of the left side of the scrotum was noticed, as well as some œdema of the right. There was also some ecchymosis in the skin, especially on the left side, and both œdema and discolouration of the penis, most marked at the preputial fold. Mr. Bland-Sutton operated the same afternoon. An incision about 3 inches long was made over the anterior aspect of the left side of the scrotum. The skin and dartos were œdematous and contained a good deal of effused blood of a dark colour. When the tunica vaginalis was incised it was found to contain about an ounce of blood-stained fluid. On its posterior aspect, behind and outside the testes, was a vertical tear some 2 inches or 2½ inches long and almost straight. The edges of this tear appeared clean-cut and not jagged, and beyond it was a cavity in the cellular tissue of the scrotum, containing some amount of clotted blood. This was cleared away and a radical cure performed. The greater part of the parietal layer of the tunica vaginalis was removed and the testicle invaginated into the remainder, which was secured around it by two stitches. A drainage-tube was inserted, and on account of the œdema two stitches only were used to unite the skin. The œdema rapidly became less, and on the fourth day after operation had so far decreased that five extra superficial stitches were added. The wound healed slowly without suppuration, and the patient was discharged on April 4th. Unfortunately, no microscopic examination of the tunica vaginalis was made in this case.[2]

CASE 2.—The second case is that of a journeyman baker, 43 years of age. Except that he had had a left-side hydrocele for five years, there was nothing noteworthy in his previous history. The man had a sallow, unhealthy appearance, the result of his employment, and his arteries were rather thickened. He stated that he had never had syphilis, and that he was a moderate drinker, but occasionally, as he expressed it, "went on the spree." He had had his hydrocele tapped in June, 1906, when 22 ounces of fluid were removed, and again in March, 1907, when 20 ounces were drawn off. The hydrocele had again filled and extended as high as the internal abdominal ring, the swelling being most marked above. It was beginning to cause him inconvenience by its size, and was slightly tender, so that he had made up his mind to come to the hospital in a few days time to have it tapped again. He had no recollection of ever knocking the hydrocele, but on April 11th, 1908, he noticed that the swelling had become softer and more tender than usual. On April 12th this condition became more noticeable, and the chief swelling being in the lower part of the scrotum instead of above as previously. To quote the man's own words, his hydrocele "had dropped all flabby like a busted football." There was also discolouration of the skin on both sides of the scrotum.

On April 13th the pain became so severe that the man was unable to continue at his work, and he came to the Middlesex Hospital. The scrotum was then found to be œdematous, especially on the left side. The right testicle could be felt, but the left could not be made out, although testicular sensation was obtained on both sides. Neither fluctuation nor translucency was present. The skin of the scrotum was discoloured on both sides, but especially on the left. The next day (April 14th) all œdema on the right side of the scrotum had disappeared. The left testis could not be made out, but fluctuation was obtained, and the fluid could be displaced from the lower part of the scrotum to the external abdominal ring.

On April 23rd the patient was admitted to the hospital. Practically all œdema and discolouration of the skin of the scrotum had disappeared. The hydrocele felt tenser than before. On April 29th, through the kindness of Mr. Bland-Sutton, I performed a radical cure of the hydrocele. An incision 2 inches long was made over the upper part of the left side of the scrotum. A thick-walled hydrocele sac was opened. The contents of the sac were clear serous fluid, and the inner surface of the sac was smooth generally, but nodular where it covered the testis. The wall of the sac was everywhere thick, and consisted of a double membrane. To the inner side of this sac was a second nearly as large as the first. It was subcutaneous, and lined by a thin serous membrane. It contained blood-stained fluid and had ruptured posteriorly. The septum between the two sacs was thick and dense, but at one point it was much thinner and bulged toward the thin-walled sac. As much as possible of both sacs was dissected away, and a running stitch applied round the cut edge of the tunica vaginalis where it was reflected on to the testis to limit hæmorrhage. The serous surface of the testis was then wiped with raw carbolic and the wound closed.

A microscopic examination of the thickened tunica vaginalis showed it to consist of dense fibrous tissue with thick-walled arteries. The fibrous tissue was moderately cellular and contained elongated cells, with abundant protoplasm, and a small round nucleus. It is quite clear that in the above case it was the thin-walled sac and not the tunica vaginalis that had ruptured. It would seem probable that this sac was secondary and due either to a previous rupture of the tunica vaginalis and the fibro-muscular coat, or to a leakage after tapping. It may be that the thin bulging area noted in the intervening wall between the two sacs represented a previous communication between them.

[2] This case has been previously published in the Archives of the Middlesex Hospital.

CASE 3.—On April 3rd, 1909, a shop assistant, aged 24 years, was admitted to the Middlesex Hospital for ruptured hydrocele. There was nothing special in his family or previous histories. About a year before admission he noticed a swelling in the left side of his scrotum. It appeared spontaneously and steadily increased in size. In about three months, though there was no pain, it became so inconveniently large that he consulted a medical man, who pronounced it a hydrocele and tapped it. For two months all went well, but after this the hydrocele began to fill up again, and after attaining the size of an orange remained stationary. On April 3rd, while leaning over a billiard table, the young man knocked his scrotum. The blow was quite slight, but immediately he felt an acute pain, which, as he expressed it, "doubled him up." In a few minutes the pain became less acute, so that he was able to finish his game, but a dull aching followed. He examined his scrotum, and finding it swollen and discoloured came at once to the hospital and was admitted.

On admission, the scrotum was seen to be swollen to the size of a cocoanut and discoloured by extravasated blood. The discolouration was general, though most marked below, but the swelling was almost confined to the left side. The scrotum was very tender. The swelling was tense and fluctuation was obtained, but it was not translucent. The testicle could not be felt. There was some œdema of the skin of the penis and prepuce, which were slightly discoloured.

On April 5th Mr. Bland-Sutton decided to operate. A vertical incision 3 inches long was made downward from a point a little below the left external abdominal ring. Much blood clot was found in the scrotal tissues. The tunica vaginalis was opened by deepening the incision, and found to contain blood-stained fluid and clot. When this was removed a vertical tear some 2 inches long was seen extending through the parietal layer of the tunica vaginalis on the outer side. A portion of the thickened tunica vaginalis was removed and the remainder everted and sutured behind the testis. A drainage-tube was inserted, and the wound was closed. The man made an uninterrupted recovery. On April 21st he left the hospital, the wound being completely healed.

Microscopic examination of portions of the thickened tunica vaginalis removed at operation two days after the rupture showed it to consist of dense fibrous tissue. Between the fibres were a fair proportion of elongated fibroblasts and small round cells. The rather numerous blood-vessels were in no way thickened, but were immediately surrounded by a large number of small round cells. It is interesting to note that the thickening of the tunica vaginalis was by no means uniform, being much more marked in some parts of the membrane than in others.

Abstract.—Rupture of the tunica vaginalis in hydroceles is probably a more common accident than is usually supposed. It may occur as the result of traumatism or muscular action or may occasionally take place spontaneously. In practically all cases the tunica vaginalis which gives way is the seat of pathological changes, usually of the nature of an irregular fibrous thickening. The rupture may occur at any point and usually involves the serous layer only, but occasionally the fibrous tunic is torn also. The accident only occasionally results in cure, and more usually the hydrocele slowly refills or a hæmatocele is produced. The best treatment is radical cure of the hydrocele, which is most advantageously performed after the greater part of the effused fluid has been absorbed.

PRESENTATIONS TO MEDICAL MEN.—Mr. William Monckton, M.R.C.S. Eng., L.M., L.R.C.P. Edin., has been presented with a cheque for 100 guineas, an album suitably inscribed and containing sketches of Portishead, Somerset, together with an illuminated address with a list of about 400 subscribers, as a mark of respect and esteem, on the occasion of his leaving Portishead.—At a supper held at Redruth, Cornwall, on March 16th the members of the Dolcoath division of the St. John Ambulance Association presented Mr. Josiah Telfer Thomas, L.R.C.P. Lond., M.R.C.S. Eng., J.P., with a solid silver inkstand, suitably inscribed, "in grateful recognition of his services as honorary surgeon."

WASSERMANN'S REACTION FROM A PRACTICAL POINT OF VIEW.

BY J. E. R. McDONAGH, F.R.C.S. ENG.,
CHIEF ASSISTANT, SKIN DEPARTMENT, ST. BARTHOLOMEW'S HOSPITAL, ETC.

MUCH has already been written concerning the theory of Wassermann's reaction, but its practical bearing has received too little consideration. It is unnecessary for a busy medical man to burden himself with the theory of a test which can only be carried out in a well-equipped laboratory, with a menagerie attached. However the reaction may be simplified, it can never form a sport for the consulting-room—letting the patient have an answer while he waits. The more recent modifications of subsequent workers have one and all by yielding variant and uncertain results unfortunately seemed now and again to deduct from the value of this important advance in syphilology. Such discredit, however, is not justly to be ascribed to the technique originally introduced by Wassermann, but no sensible improvement upon that method has so far established itself in the favour of authoritative workers, and at the present moment, therefore, it is a fact that Wassermann's original test of the year 1906 still holds the field as the approved as well as the most reliable of all. No doubt Wassermann's original method entails more labour, since every ingredient of the reaction is used in a known quantity. It, however, gives results, both qualitative and quantitative, which cannot be attained by any of the modifications. The reaction itself is empirical, therefore every care should be taken to obviate any source of error. The rational interpretation of the scientific meaning of the reaction will not be arrived at by taking any of the "short cuts" proposed in these modifications; it will rather be reached by trying to ascertain (1) why an extract of a guinea-pig's heart (antigen) should have the power of binding the complement with a syphilitic serum, and (2) why every case of florid syphilis does not give a positive reaction. The answer to the former will no doubt be given us by the chemists, while it is more than likely that the reaction is a chemical one. Concerning the latter we shall have something to say below. Be the reaction, as carried out by Wassermann, empirical as it may, it is nevertheless one of the greatest advances of modern medicine, the name of Wassermann being to syphilis what that of Widal is to enteric fever.

FIG. 1.

Spirochæta pallida. × 500. From a photograph kindly lent by Dr. Mucha.

Take first of all the *primary stage of syphilis.* In no stage of the disease is diagnosis so important. Seen early, a sore on the penis may baffle even the elect. One or other of two courses is usually adopted. Either the patient is given mercury and so labelled as a syphilitic, with a three years' treatment to look forward to and the constant thought of suffering from a disease which is popularly regarded as incurable—the word syphilis, to the man in the street, has more foreboding than is realised by the man in the hospital; or the patient must wait until the whole system is infected and until there are rash, sore-throat, and evening headache, that is to say, until secondaries are obvious enough to be diagnosed by a layman.

The use of Wassermann's reaction is limited. Taking all periods of the primary stage a positive result is not obtained in more than 40 per cent. of cases.

A positive diagnosis can be obtained only by finding the spirochæta pallida. The secretion of a sore should be examined by means of the "dark ground illumination." No staining is required, and the spirochæta can be seen in the living state. The method is perfectly simple, and can be carried out in a few minutes while the patient waits. The secretion from a primary sore hardly ever fails to reveal the spirochæta pallida, and this organism is not found in other sores.

The "dark ground illumination" is obtained by using a condenser which allows no rays of light to reach the eye of the observer, except those reflected by certain objects, such as the spirochæta, under observation. The picture represented on the slide is one not easily to be forgotten, since the spirochæta is seen wriggling its corkscrew-like form, which is brightly illuminated, across the dark non-transparent background. The question of distinguishing the specific spirochæta from the *S. refringens* need not arise, since the latter is rare in the secretion of a chancre, and does not occur in other venereal diseases until a stage so late that a wrong clinical diagnosis is impossible. Should it be required to discriminate between the two by the above method, it is only necessary to remember that the *S. refringens* is thicker, has fewer turns to its corkscrew, is usually of a yellowish tint, and, when moving, moves along its whole length; while, on the other hand, the *S. pallida* is finer, has more turns, tapers at both ends, appears dead white, and, when moving, a part may remain stationary while the rest is in motion, giving one the idea that its corkscrew is kinked.

An even simpler and equally reliable method—one requiring no special apparatus—of demonstrating the spirochæta is by means of Chinese ink (Burri's method). A platinum loopful of secretion from a sore is placed upon a slide, surrounded by seven or eight loopfuls of distilled water and the same quantity of a solution of Chinese ink (Günther and Wagner). The whole is mixed and spread out on the slide, as a blood film is made, allowed to dry, and examined with an oil immersion lens. The ink produces a dark background and the objects under examination stand out white, as in Fig. 1.

Should the *S. pallida* be found before the patient gets a rash or general symptoms, and the chancre be so situated as to be easy of removal, it should be removed by the knife, because cases have occurred where, after excision of a true chancre in which the *S. pallida* was proved to exist, neither secondary nor tertiary symptoms have followed. Such cases are exceptional and secondaries usually do appear, but when they do their severity is certainly diminished by excision.

It is wise, then, to *place no reliance upon a negative Wassermann in the primary stage.* If positive the course is clear; the patient has undoubtedly syphilis and should be treated as a syphilitic.

Secondary syphilis.—In this stage a positive Wassermann is obtained in 85 per cent. of *all* cases—cases alike where an eruption is present, where there is no manifestation at the time, and where the patient is undergoing treatment. When there is a rash and the patient has not yet had any mercury no less than 97 per cent. give a positive result. This is sufficient indication to start treatment and is proof positive of the rash being syphilitic, for one never gets a positive reaction in a non-specific case. When no sign is present 80 per cent. of cases in the secondary stage are positive.

The positive cases should receive treatment at once. The other 20 per cent. may be negative: (1) because the syphilitic virus has disappeared or is dormant and there is no specific antibody in the serum; (2) because the patient is taking mercury; and (3) because the patient forms one of the 3 per cent. who in any case give a negative reaction. Having sufficient evidence that in the first of these categories the patient has had syphilis, and that he has not received at least two years' treatment in spite of the negative reaction, treatment should be continued till the end of the third year.

A word on *treatment in general.* Treatment can be

divided into two classes: (*a*) continuous; (*b*) intermittent. In this country the continuous treatment is the rule—i.e., mercury is given internally for a period of two or three years. On the continent the intermittent treatment is more in vogue—i.e., a patient receives so many courses in the three years. A course of inunctions and injections lasting about six weeks is given two or three times a year. The influence of the Wassermann reaction on the continuous treatment cannot be estimated, since, if a patient has been told of the necessity of taking pills for three years he will object if his doctor changes his mind and knocks him off to have his blood examined, because a sufficient interval must elapse from the last dose of mercury before the test is carried out, owing to the tendency of mercury to convert a positive into a negative result.

The influence on the intermittent treatment is different. Directly after a course the reaction is usually negative; when positive the course should be prolonged. When the mercury, hastened by the use of iodides, has been eliminated from the system the reaction may be positive or negative. The greater the number of previous courses, the more likelihood there is of a negative result; but such cases almost invariably become positive the moment symptoms reappear. There is no doubt that syphilis may run a mild or a severe course, and it is not unlikely that some cases do not require the three years' treatment. Whether this is so or not can only be proved where the treatment is intermittent; the time is not far distant when we shall be able to say whether further treatment is necessary or not. For instance, should a case give a negative reaction three, six, and nine months after the last course it can be considered cured. This would be a tremendous advance, since every patient becomes anæmic, loses weight, and becomes depressed from the prolonged use of mercury. At present the reaction is not certain enough to be relied upon to this extent; while it shows the advantage of the intermittent over the continuous treatment, it does not at present entitle us to depart from the three years' *régime*.

One other point as regards treatment. The earlier the disease is diagnosed and the more vigorous the primary treatment is, so much the sooner will a permanent negative reaction be given. The most vigorous of all forms of treatment is by inunction daily under medical control, no "rubbings" being given at home. The mercury gets into the system quickly, and the amount absorbed can always be gauged by the straight line the gums take, especially below the incisor teeth of the lower jaw. Injections are less potent and oral administration very much less. Pills are especially liable to cause a stomatitis, a stomatitis not due to an overdose of mercury, since the sore mouth and gums, &c., get well at once if injections are used. Pills no doubt predispose to chronic superficial glossitis and cancer, since syphilis is more common on the continent than in England, but tertiary lesions of the tongue and mouth are very much more common in England than on the continent. Patients with tongue lesions, even those who have taken pills regularly for years, always give a very strong positive reaction; and in most cases the condition steadily gets worse as the pills are continued but improve when injections are given. It is not uncommon to find that late syphilitic lesions with a positive reaction, however vigorous the treatment may be at the time, never give a negative reaction. Wassermann's reaction shows us the enormous benefit which arises from an early and vigorous treatment of the disease and the advantage of inunctions and injections over oral administration of mercury.

Tertiary syphilis.—There is no hard-and-fast line between secondary and tertiary syphilis, since gummata may occur as early as the eighth month after infection. For convenience sake we will consider under this heading cases which come up after a three years' treatment. Patients with obvious gummata or other syphilitic manifestation should at once receive mercurial treatment—not potassium iodide alone, as is so often given. A gumma means that the syphilitic virus is still active, and as mercury is the only specific drug the presence of a gumma is sufficient reason for its use. Combine it with iodides by all means, but it is better to give a course of mercury and follow it up with iodides, since the latter aid elimination of the excess mercury which has accumulated in the system.

Taking all patients in the tertiary stage, 70 per cent. give a positive result. Many have no symptoms and give a negative result; these may be regarded as cured. Others have no symptoms but yet give a positive result; in these suspect some visceral lesion, such as internal gummata, arteriosclerosis, aortic disease, or the nervous manifestations. When a positive result is given, treatment should be started, except in cases of tabes or general paralysis of the insane, in which mercury usually tends to aggravate and to hasten the course of the disease.

100 per cent. of cases of general paralysis of the insane and about 60 per cent. of cases of tabes give a positive reaction. This high percentage is probably due to the lack of signs of syphilis in the earlier stages of the disease, which also means a lack of treatment. Several cases are reported where a patient had a sore with no obvious secondary symptoms, but followed by tabes or general paralysis of the insane in later years.

Wassermann's reaction is extremely useful in such cases as: (1) that of a man who gives a history of a sore which appeared a few days after connexion and disappeared within ten days or a fortnight. No notice is taken at the time, but some months later a few spots appear on the body and a medical man is consulted. He cannot be quite sure about these spots. Where there is doubt the possibility of syphilis is always present. Mention of a sore on the penis some months previously confirms the diagnosis. To clear up the diagnosis mercury is given, and the spots vanish or remain. Laymen are sufficiently well educated nowadays to know what mercury means. Some are convinced that they are suffering from syphilis, and may not trouble about it until they want to get married. Or they are not satisfied and require a second opinion. In such cases the history should be carefully gone into and the blood examined not less than one month after cessation of mercury, iodides having been given for the first three weeks. If the result is negative the patient can with safety be informed that he can marry, that no further treatment is necessary, and that the probability of his ever having had syphilis is remote. (2) Differential diagnosis between varicose ulcer and gumma, which may be difficult, and since ulcers usually occur in women history throws little light upon the case; (3) diagnosis between gummata of the testes, tubercle, and new growth; (4) diagnosis between gummatous periostitis and sarcoma—limbs with syphilitic periostitis have been amputated for malignant disease; (5) diagnosis between gumma and malignant growth of the liver; (6) diagnosis between syphilitic disease, tubercle, and carcinoma of the rectum; and (7) in the case of a man who has had well-treated syphilis and is anxious to know whether it is safe for him to marry. In the last mentioned case it is wise to allow three or six months to elapse after the last treatment, before the blood is examined. If the result is positive advise against, if negative for, marriage.

A syphilitic woman, or a woman who has aborted several times and gives a positive reaction, may, if rigorously treated during her pregnancy, produce a healthy child. In such a case the child's blood should be tested as soon as possible after birth. If the reaction is positive it should receive a two years' treatment; if negative, it can be considered free of hereditary taint.

Colles's law tells us that a syphilitic child may be born to a syphilitic father without its mother being infected, she being rendered immune. Profeta's law tells us that a healthy child may be born of a mother who became infected during pregnancy, and that the passive immunity of such a child disappears before puberty. Wassermann's reaction shows that in both cases the supposed immune person gives a positive result, and therefore must be regarded as syphilitic and infectious.

Such being the case, the following suggestions must be made:—1. When a man infects his wife both should be rigorously treated, and the woman should be re-treated during each pregnancy. 2. (*a*) A syphilitic woman should be treated during the whole nine months of her pregnancy. (*b*) An apparently healthy woman whose blood gives a positive reaction should be so treated during each pregnancy. 3. (*a*) A syphilitic child should be suckled only by its mother, never by a wet nurse. (*b*) An apparently healthy child, either of whose parents has had syphilis, should only be suckled by its mother. (*c*) Should such an apparently healthy child react positively to Wassermann's test, it should receive antisyphilitic treatment. A positive reaction can be obtained in a congenital syphilitic on the day of birth.

A congenital syphilitic is peculiar, in that mercury has

little influence in converting a positive into a negative reaction. Children who have had congenital syphilis, and who have received treatment, show no signs for years, yet not infrequently react positively. Such being the case, no rule can be laid down as to how long a syphilitic infant should receive treatment. As our knowledge stands at present, it is safest to give mercury over a period of two years.

The importance of diagnosis in a congenital syphilitic, who has never shown symptoms, is great, since the reaction has shown the possibility of the next generation inheriting the disease.

Life insurance.—Wassermann's reaction is now entitled to play an important rôle in determining the knotty problems of life insurance. The statistics quoted above are decisive on this point. A proponent with a recent history or with present manifestations of syphilis is, according to present custom, rejected or deferred by most offices. This is a sound principle. But the facts and conclusions cited in this article justify a closer scrutiny of all syphilitic cases. A candidate giving a positive reaction, even though years may have elapsed since the original infection, should be regarded as ineligible, for such a result usually signifies the presence of a visceral lesion that will ultimately shorten life. The virus has obtained such a firm hold that treatment, while capable of checking its course, can never thoroughly get rid of it. Furthermore, a candidate yielding a positive reaction after shorter lapses of time—say, three years from the date of the primary lesion—should be received with caution, for this usually denotes that the early treatment of the patient has been insufficient and inadequate, with consequent liability to the later manifestations of the disease. On the other hand, a candidate may be accepted who, having completed a two years' course of treatment, shows a negative reaction on being tested at intervals of three, six, and nine months after such a course. The influence of syphilis on his chances of life may now be safely discounted. In no case is acceptance warrantable until two years have elapsed since the original infection.

After reading this article the question will naturally be asked, Why is it that 100 per cent. of cases—in other words, all cases—of florid syphilis do not give a positive reaction? The answer very probably is that, whilst inactivating the patient's serum to rid it of its complement, the first action of the rise of temperature is to cause in some cases a linking of the complement with the antibody which is present in the serum. This would produce a diminution of free antibody, therefore all the fresh complement from a guinea-pig's serum added in the test could not be used up; some would remain free, which combining with the amboceptor from the rabbit's serum, would bring about hæmolysis of the sheep's red blood corpuscles.

The complement in a human serum disappears by the third day, even when the serum is kept at a temperature of 0° C. If, then, a patient's serum is kept four or five days and not inactivated by the usual heating many of the cases which gave a negative result now give a positive result. 1500 cases have been described [2] where the serum was used, both active and inactive, with the most gratifying results in favour of the former over the latter method.

Wechselmann in Wassermann's Laboratory [3] has made the most interesting experiments to rid the serum of all its complement. He takes 0·9 cubic centimetre of active serum + 3 cubic centimetres NaCl solution + 0·5 cubic centimetre of a 7 per cent. emulsion of fresh precipitated barium sulphate. After well shaking this mixture is put into an incubator at 37° C. for an hour and then centrifugalised. 1 cubic centimetre of the solution is used for the reaction. From 41 cases which had given a negative reaction 38 of these tested in this way gave a positive one. This will make a negative reaction of enormous value, and after testing some hundreds of cases we shall very soon be able to regulate our treatment by means of the reaction.

With regard to the technique of the operation the patient's blood is best obtained from the finger pulp. The instrument as figured (Fig. 2) has a four-surfaced blade, sharp at the point and two sides; at the base is a neck which prevents the blade, which is 5 millimetres in length, from penetrating too far. One quick plunge is made, the finger "milked," and as much as 3 cubic centimetres or more of blood are quite easily obtained; 0·5 or 1 cubic centimetre is really quite enough. This instrument does not hurt the patient nearly so much as the usual needle, which is blunt at one side, and it has the further advantage of making it easy to get as much blood as is required. Taking blood from the finger is, both from the

FIG. 2.

patient's and the doctor's point of view, more satisfactory than bleeding a vein in the forearm. The pulp of the finger should be cleaned first with absolute alcohol. After enough blood has been obtained a piece of strapping, cut in the usual shape of a finger-dressing, should be applied to the finger with a piece of gauze fixed to the sticky surface of the strapping. This strapping can be removed in 12 hours.

A CASE OF TETANUS TREATED WITH SUBCUTANEOUS INJECTIONS OF MAGNESIUM SULPHATE; RECOVERY.

BY PETER PATERSON, M.B. GLASG.,
SURGEON, ROYAL INFIRMARY, GLASGOW.

SINCE Meltzer, in 1905, showed that paralysis of nervous tissue could be induced by magnesium salts, a considerable number of tetanus cases have been treated with solutions of this salt and with highly gratifying results. The majority of the recorded cases have been treated by subarachnoid injections, while in a few the salt has been introduced into the subcutaneous tissues, but in most, if not all, these injections have been regarded as supplementary to the serum treatment. Wassermann, Babes, Kowalski, and others have had encouraging results from frequently repeated subcutaneous injections of a fine emulsion of rabbit's brain in normal saline solution. This fresh nervous matter acts, in all probability, by combining with the tetanus toxin circulating in the blood, and thus its absorption by the nervous system of the patient is prevented; it can have no action on the toxin already fixed in the patient's nerve cells. Magnesium sulphate, again, has no effect on the toxin, either fixed or free; hence, so long as toxin is being formed at the seat of infection, injections of this salt do not prevent its absorption by the nervous system. It only acts by controlling the spasms, and, by conserving the patient's strength, gives him time to form his own antitoxin. If, then, both brain emulsion and magnesium sulphate were injected at the same time, it seems to me that the patient would have a better chance of recovery than when only one of these is administered, as the magnesium salt would diminish the spasms produced by the toxin already fixed, whilst the brain emulsion would prevent, or at any rate diminish, absorption.

In the case of which the following is a short summary only the magnesium salt was employed. The patient, a coal-miner, 21 years of age, was admitted to hospital three weeks after he had received a small wound on the scalp from a kick. This wound must have been a very superficial one as it healed in a few days and left no visible scar; in fact, it is doubtful if this actually was the seat of infection as his hands showed numerous small cuts and abrasions, any one of which might easily have given entrance to the bacillus. The symptoms commenced six days before admission with pain and stiffness in the abdominal

walls and muscles of the back. These pains gradually became worse, till on the morning of admission he had a "convulsion" which lasted about five minutes. When brought under observation the whole body was rigid, with the exception of the forearms and hands. Opisthotonos was well marked; the legs could not be moved, and the incisor teeth could be separated for about an eighth of an inch only. All the affected muscles were very hard. He complained of severe and continuous pain across the upper part of the abdomen and down both legs. Superadded to the tonic contractions of the muscles there were almost continuous cramp-like spasms. Every two or three hours these became very severe, and implicated, not only the muscles of the trunk and limbs but also those of respiration, so that breathing was suspended, the face became cyanosed, the pupils dilated, the pulse thready, and occasionally consciousness was lost. The temperature was 100° F., the pulse 96, and of moderate tension. A count of the white blood cells gave 12,000 per cubic millimetre, of which 84 per cent. were polymorphs. Perspiration was free but not excessive. The urine was free from albumin. During the night he was very restless and did not sleep.

The following day he received a subcutaneous injection of 10 cubic centimetres of a 10 per cent. sterilised solution of magnesium sulphate, 5 cubic centimetres being introduced into each thigh. Soon after this injection he obtained an hour's sleep, the first he had had for 48 hours. These injections, which were repeated every four hours, night and day, for two days, gave him so much relief that he frequently cried for them, even though they were very painful. After two days of this treatment the comparatively slight and more frequent spasms had almost entirely disappeared, the pain had become much less acute, and the severe spasms had become less frequent, there being one only every 5 to 12 hours instead of every 2 to 3 hours as formerly. As these were still so severe as to threaten life the dose of the magnesium sulphate solution was rapidly increased till 20 cubic centimetres were administered at one time, 10 cubic centimetres being injected into two separate parts of the body at one time. This increased dose was repeated every four hours and continued for four days. The effect of this treatment seemed to be a prolongation of the interval between the spasms, there now being only one, or at most two, in the 24 hours. The rigidity of the jaws, abdomen, and back was still present, but that of the legs was passing off, as he was able to draw them up in bed, though with difficulty. The injections were now stopped, partly because the spasms were diminishing in frequency and partly because he was strongly objecting to the pain they caused him. The day after the treatment was stopped an erythematous rash appeared over his shoulders and gradually spread, till three days later the greater part of the body was covered; it then began to fade and a week later had disappeared. This rash did not give rise to any evident constitutional symptoms. At the same time he suffered much distress from a collection of viscid saliva at the back of his throat. This mucus could not be swabbed away as he could not open his mouth sufficiently to permit this, and he was afraid to cough it up in case the exertion should produce a spasm. The last severe spasm was recorded three days after the injections had been stopped, and though he still had at long intervals slight attacks of cramps, his chief complaint was the pain resulting from the injections. The rigidity was now becoming less marked, though it varied in degree from time to time. At one visit the legs, for example, could be moved quite freely, while at the next movements could only be performed with difficulty. Evidently relaxation was not a continuous process but was interrupted by a series of long drawn out, painless, and ill-defined waves of tonic contractions, slight in degree. The abdominal muscles were the last to lose their board-like rigidity.

The patient left hospital five weeks after admission. When seen three weeks later he was about to return to his work. Throughout his illness he could swallow without difficulty, and as his thirst was great he was able to take a large quantity of nourishment. The thirst was specially marked during, and for a few days after, the administration of the injections. During this period he took on a daily average 8 to 10 pints of fluid, consisting of strained soup, milk, water, and an occasional beat egg. The quantity of urine was not increased, but he lay soaked in perspiration. The latter may have accounted for his thirst, though the introduction of so much salt into the circulation may have been partly responsible. The bowels moved two to three times daily, and the motions were inclined to be loose. The temperature never rose above 101° F., but it did not fall to normal till four weeks after admission and fully a fortnight after the spasms had ceased. The pulse varied from 100 to 120, except during a spasm, when it would mount to 130 or 140 per minute.

It would have been safer, perhaps, to have continued the injections for a day or two longer, but they were stopped for the reasons already mentioned. The great objection to this method of treatment is the pain produced by the injections, but I think this could be overcome to a considerable extent by using larger quantities of a weaker solution.

Glasgow.

TWO CASES OF HÆMORRHAGE FOLLOWING GASTRO-ENTEROSTOMY WITH CLAMPS.

BY ROBERT OLLERENSHAW, M.D. VICT., F.R.C.S. ENG.,
HOUSE SURGEON, MANCHESTER ROYAL INFIRMARY.

With a Note upon the Cases by J. E. PLATT, M.S. Lond., F.R.C.S. Eng., *Honorary Surgeon to the Manchester Royal Infirmary; Lecturer on Practical Surgery at the University of Manchester.*

Mr. Sinclair White's report in THE LANCET of Jan. 22nd of a case of hæmorrhage after the use of clamps in gastro-enterostomy, the letter of Mr. R. W. Murray in the issue of Feb. 5th reporting a further example, and several cases reported in subsequent issues, have led me to record the following two cases which have recently occurred at the Manchester Royal Infirmary.

CASE 1.—The patient, a male, aged 39 years, had suffered for 13 years from pain after food and vomiting. These symptoms had gradually increased in intensity from the first onset until his admission to the medical wards of this hospital under Dr. E. M. Brockbank on Nov. 26th, 1909. At the time of admission the patient vomited several times a day, sometimes as much as three pints at once. No blood was ever vomited, and there had never been melæna. After three weeks' careful observation Mr. J. E. Platt was asked to perform gastro-enterostomy. This operation was carried out on Dec. 17th. A dilated and toneless stomach was found with cicatrices on the anterior surface near the pylorus. Posterior gastro-jejunostomy was performed with no loop and without reversal. Two rows of sutures were used, an outer serous layer and an inner layer passing through the whole thickness of the wall of the stomach and jejunum. The sutures were placed about one-eighth of an inch apart. The clamps used were of Doyen's pattern and they were removed immediately before the anterior serous layer of sutures was inserted. The patient at the end of the operation showed no signs of shock; the pulse was of good quality and about 80 per minute. He was put to bed in the Fowler position. During the same evening he seemed very comfortable and had frequent mouth washes. He was given 6 ounces of saline solution per rectum every four hours and 12 hours after the operation he was allowed small sips of hot water. On the following morning the patient's condition was excellent; the pulse was 76, the temperature was 98·2° F., and the abdomen was moving well and was not at all distended. At 4 P.M. he awoke suddenly from sleep, complaining of an aching pain in the abdomen. He at once collapsed and presented a typical picture of hæmorrhage—great pallor with cold perspiration, quiet sighing respirations, and a pulse of 130 per minute and almost too "thin" to be felt. He was given 10 ounces of saline solution per rectum, and a hypodermic injection of 10 minims of digitalone. His breathing was extremely shallow, and he was given oxygen inhalations at intervals during the next two hours, at the end of which time he showed considerable improvement. From this time onwards until his discharge on Jan. 10th, 1910, the patient rapidly recovered without any further interruption. On the evening of the day following the collapse he passed two large semi-fluid stools, quite black in colour, and consisting almost entirely of altered blood, thus confirming our diagnosis of hæmorrhage.

CASE 2.—The patient, a man, aged 49 years, was admitted to the hospital, under Dr. Brockbank, on Jan. 12th, 1910,

having suffered for a year from epigastric pain which came on two or three hours after food and was always relieved by taking food. These symptoms had become steadily worse, with the exception of a month's interval during last summer, when he was medically treated in this institution. There had latterly been occasional vomiting after the pain has occurred, but there had never been hæmatemesis or melæna.

The patient was admitted to the surgical wards on Jan. 27th, 1910, under Mr. Platt, who operated four days later. The stomach was found to be slightly dilated, cicatrices were present in the first part of the duodenum close to the pylorus, and there were numerous adhesions between the duodenum and the gall-bladder. The operation was precisely the same as the one previously described, with the exception that instead of Doyen's clamps the pattern known as the Roosevelt-Moynihan clamp was used. There was no shock after the operation and the patient was quite comfortable and progressing well until the following afternoon, when he suddenly gave a cry and complained of pain in the umbilical area. He was quite collapsed and his pulse became "thin" and rapid (136). He was given 10 ounces of saline solution per rectum and a hypodermic injection of morphia (5 minims) was administered. After about half an hour he showed some improvement; in three hours he was considerably better and a further 10 ounces of saline solution were given. On the day following he passed a fluid stool which was quite black and which measured about 16 ounces. Since that time his progress has been uninterrupted.

I am greatly indebted to Mr. Platt for his permission to publish these cases.

Note by Mr. PLATT.—The two cases above mentioned are the only cases of gastro-enterostomy I have done in which I have reason to suspect that there has been any subsequent hæmorrhage. In the second case the stomach wall was more vascular than usual, and I therefore placed the inner row of sutures very close together. It appears probable that there is little risk of hæmorrhage from the jejunum, and that the bleeding is most likely to come from the side of the stomach incision near the greater curvature. As a means of retaining the advantages of clamps and at the same time obviating the risk of subsequent hæmorrhage, I would suggest that after the posterior rows of sutures are inserted the stomach clamp be loosened and the main bleeding points picked up. The clamp can be then tightened again and the anterior suturing completed. I have several times adopted this procedure in order to complete the diagnosis when I have been still in doubt after an external examination of the stomach, and in this way have been able to decide definitely whether one had to deal with a simple ulcer or a malignant condition.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

PATHOLOGICAL SECTION.

Gastric Analysis.—Pernicious Anæmia.—Amyloid Degeneration in an Adenoma.—Primary Carcinoma of the Liver.

A MEETING of this section was held on March 15th, Dr. F. W. MOTT, the President, being in the chair.

Dr. W. H. WILLCOX read a paper on the Diagnostic Value of the Chemical Analysis of the Gastric Contents after a Test Meal, which we shall print in a future issue.

Dr. F. H. THIELE read a paper on Some Observations of the Pathology of "Pernicious" Anæmia, and compared them with two cases of aplastic anæmia. With regard to the pernicious anæmia, complete examinations were made of 15 cases. The duration of these varied from three months to four years. The great characteristic of the blood examination was the megalocytosis; in no other form of anæmia was this so striking. Besides the megalocytes there were numerous microcytes in all the cases. Nucleated cells, even after prolonged searches, were not always found, and this was especially the case with regard to megaloblasts. Furthermore, as with the non-nucleated cells, all gradations in size from the normocyte to the megalocyte were met with, so all gradations in size and character of nucleus from the typical normoblast to the typical megaloblasts were encountered, and, in fact, typical gigantoblasts as seen in the marrow and described by Ehrlich were quite infrequent, and if the megaloblastic criterion of Ehrlich had been adopted some of the cases would not have been included under this group. Two cases were recorded in which the red cells at the onset of the condition had the characters of those met with in ordinary anæmias, which later more or less rapidly took on the megalocytic type. In most cases during complete quiescence the red cells lose this character, but in some of the cases here noted the cells retained this feature, even though the patient was well for years without any symptom of the disease. In nearly all the white cells were diminished and there was a relative lymphocytosis. The marrow in all the cases was increased and had become deep red in the shafts of the long bones and showed the typical characters described by Muir. In some, however, in addition, the leucoblastic change was very prominent. The liver, spleen, and kidneys contained large quantities of iron, except a few in which the amount of iron in the liver was scarcely above normal. The amount in the spleen and kidneys, however, was quite large, in fact somewhat higher than in the other cases. The amounts bore no marked relationship to the duration of the disease. In all cases there were some changes in the alimentary canal. Pyorrhœa alveolaris was present in 80 per cent. of the cases, glossitis in 50 per cent., gastric lesions from small round-celled infiltration and some loss of glands to complete atrophy were present in 75 per cent., and intestinal lesions in 66 per cent. The lesions in the intestine were all fairly recent in appearance. In three cases there was great enlargement of the spleen, which in all contained a large amount of iron, and peculiarly showed some recent perisplenitis. The urine in all cases contained excess of urobilin, and jaundice occurred at intervals in quite a marked proportion. In one case there was marked combined sclerosis of the spinal cord; in another, peripheral neuritis. Subjectively gastro-intestinal symptoms were prominent in all cases, vomiting, diarrhœa, abdominal pain, girdle pains in the epigastrium, &c. The cases of aplastic anæmia both occurred in strong male subjects. The course was very rapid. Purpuric lesions were marked in both cases. Pyorrhœa was present in both, as well as inflammatory lesions in the tongue, and in one there were intestinal lesions. The blood showed excessive oligocythæmia, there was no megalocytosis, no nucleated cells, but microcytes occurred. The colour index was very low. The white cells were greatly diminished and there was a relative lymphocytosis. The marrow of the epiphyses and long bones in both was quite yellow, and in the ribs it was pale and had fatty areas. The smears from this showed no evidence of megaloblasts, but normoblasts, myelocytes, and lymphocytes. The organs, like those of the "pernicious" anæmia type, showed marked fatty changes, and necrotic changes occurred in the liver. In one case there was no increase of iron in the liver; the other, however, had large excess in the liver, spleen, and kidneys. The urine in this case contained urobilin in excess. The points which these cases of pernicious anæmia brought out were: 1. The typical megalocytic type of blood which rarely occurs in such marked degree, apart from this disease, and its peculiar persistence even when the cause which has given rise to the megaloblastic degeneration of the marrow has ceased to operate for a prolonged period and the marrow would be expected to have recovered its normal condition. 2. The great frequency of the oral-gastro-intestinal lesions. In one case long mycotic chains of streptococci were found in the vomit, in three the streptococcus fæcalis was found on the tongue, and in two cases it was obtained from the spleen. 3. That although in the majority of cases there were large amounts of iron in the liver it occasionally occurred that there was very little, and it was possible that the hæmolysis occurred especially in the spleen, because in two of these cases the amount of iron in the spleen was the largest recorded in the series, and in one where the necropsy was performed fairly early the streptococcus fæcalis was found in the spleen. 4. The question was discussed if urobilin in excess in the urine necessarily pointed to increased hæmolysis. 5. The frequency of jaundice of slight degree pointed to the action of some toxic substance absorbed from the alimentary canal or the liver. 6. Finally the question of the position of the

aplastic anæmias was discussed and one case appeared to point to the fact that marrow hæmogenesis did not always occur in "pernicious" anæmia, where all the symptoms and post-mortem findings were characteristic of a case of this disease except the blood and marrow changes.

Mr. S. G. SHATTOCK exhibited a specimen of Amyloid Degeneration in an Adenoma of the Liver, which was of interest as being the first demonstration of this degeneration met with in a new growth. The tumour itself was of large size, and in structure closely resembled hepatic tissue. The hepatic substance itself, which was displaced over the growth, exhibited the same degeneration, the disease in this, as in the tumour, being confined to the vessels.

Dr. F. PARKES WEBER read a paper on a case of Bile-producing Primary Carcinoma of the Liver, which will be published at length in THE LANCET shortly.

THE SOCIETY OF TROPICAL MEDICINE AND HYGIENE.

Latency of Malarial Infection.—Typhoid Fever Prophylaxis.—Fever with Rash in the Yangtse Valley.

A MEETING of this society was held on March 18th, Dr. F. M. SANDWITH being in the chair.

Dr. OSWALD BAKER communicated a paper on the Duration of Latency of Malarial Infection, in which he described the persistence of latency for 13 years. He had grown old in the belief that if a person who was subject to malarial attacks took up his abode in a malaria-free country and remained exempt from any manifestation of malaria for a period of three years he might consider he had got quite rid of the infection; in other words, that the plasmodium of malaria could not exist in a latent state beyond a period of three years. But he had now abandoned that belief, which he felt sure was erroneous.

Dr. EMMETT I. VAUGHAN communicated a paper entitled "A Problem in Typhoid Fever Prophylaxis and the Solution of the Same," in which he detailed various methods of typhoid prophylaxis. The paper, which was an interesting recital of a sanitary problem that frequently arises in tropical communities, related the steps taken to solve it in the district of Gatun, Canal Zone, from the standpoint of the general sanitarian rather than that of the physician dealing with individual cases.

Dr. ALEXANDER C. LAMBERT communicated some notes on cases of Fever, with an Urticarial Rash, occurring in the Yangtse Valley. Of late years medical men stationed in the Yangtse Valley had noted the appearance in summer and autumn of a disease characterised by fever, rash, and general symptoms, pulmonary or alimentary, or both combined, accompanied also by a good deal of prostration and followed by a protracted convalescence, which happily ended in complete recovery in the vast majority of cases. Although the causal agent had not been described, there would appear to be a definite relationship between physical contact on the part of the patient with the mud in paddy-fields and creeks and shallow lakes emptying into the Yangtse, and the subsequent development of the disease a few days later. It would seem that the carrier of the infective agent of the disease was either a biting, water-haunting fly or insect or some mud-dwelling animal of similar propensities. The disease, as far as was known, was entirely confined to the Yangtse River and was not mentioned in any text-books.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.

Intraperitoneal Hæmorrhage.—Cases and Specimens.

A MEETING of this society was held at Sheffield on March 18th, Dr. W. K. WALLS (Manchester) being in the chair.

Dr. A. W. W. LEA (Manchester) reported a case of Diffuse Intraperitoneal Hæmorrhage of Ovarian Origin, probably from rupture of an early ovarian pregnancy. The patient, a multipara aged 29 years, was seen by Dr. Lea eight hours after the sudden onset of severe abdominal pain, with vomiting and faintness. She was extremely pallid, with a barely perceptible pulse, exceeding 130 beats in the minute. The abdomen was somewhat distended and extremely tender. There were signs of free fluid in the abdomen. The menstrual history showed nothing abnormal. A natural period had occurred three weeks previously. Vaginal examination revealed indistinct fulness in the pouch of Douglas, but no obvious swelling in the appendages. There was no uterine hæmorrhage. Within an hour the abdomen was opened. A large quantity of fluid and clotted blood was found free in the peritoneal cavity. There was no enlargement of the Fallopian tubes. From the surface of the left ovary projected a thin-walled blood cyst, which had obviously ruptured and was collapsed. The left appendages were removed. The right Fallopian tube appeared perfectly healthy. The patient recovered without any complication. The menstrual period commenced four days subsequently and continued for three days, being of the usual type, without pain. The specimen and a number of microscopical sections were shown. The Fallopian tube was quite normal in appearance and on section one pole of the ovary had been distended by a blood cyst which was partially destroyed during its removal. Careful examination of the blood clot revealed a small area in which the presence of chorionic villi could be clearly demonstrated in microscopical sections. Sections of the ovary showed marked dilatation of blood-vessels, with many areas of hæmorrhage in the stroma. The specimen excited considerable interest, and members were unanimously of the opinion that it would prove to be another example of ovarian pregnancy. Dr. Lea stated that further microscopical investigations would be made in order to determine the exact nature of the specimen.

Mr. R. FAVELL (Sheffield) showed an Accessory Lobe of the Liver which he had removed from a woman aged 30 years. The patient had never been well since a septic abortion six years ago. For about six months she had had pain in the right side and had noticed a lump. She had not been sick, and there had been no jaundice. She was pale and of a rather neurotic type. The abdomen was somewhat distended, and in the right iliac fossa there was a freely moveable swelling of the size of an orange. On bimanual examination the swelling could be felt at the pelvic brim. The left ovary was normal in size. The tumour was thought to be a right cystic ovary, with a large pedicle. On palpating the abdomen under anæsthesia it was noted that the tumour had the pendulum movement of a gall-bladder tumour, and that it could not be pushed into the true pelvis. The abdomen was opened below the umbilicus, and an elastic globular tumour of the size of a large Jaffa orange was seen to be attached to the liver by a short broad pedicle. The tumour was dark purple in colour in marked contrast to the colour of the liver, and its surface was marked by milky-white bands running in its capsule. Large vessels ran from the pedicle over the surface of the tumour. The pedicle was attached to the thin anterior margin of the right lobe of the liver. After clamping, the pedicle was cut through and the bleeding was controlled by a double layer of mattress sutures of catgut. The whole operation was performed outside the abdomen through an incision the upper end of which was one inch below the umbilicus. There was considerable ptosis of the liver. The patient made an uninterrupted recovery. On bisection, after hardening in formalin, the tumour was seen to be of a mottled greenish-yellow colour, and irregularly lobulated by fibrous bands and blood-vessels. The colour quickly changed to an olive-green. Microscopical section showed liver tissue undergoing fatty degeneration.

Dr. A. W. CUFF (Sheffield) read notes of four cases illustrating Difficulties in the Diagnosis of Ectopic Gestation.

Amongst the specimens exhibited were: (1) Large Fibro-Cystic Tumour of the Uterus, by Dr. J. W. MARTIN (Sheffield); (2) Submucous Myoma, which had been enucleated through the cervix, by Dr. D. LLOYD ROBERTS (Manchester); and (3) Bilateral Solid Ovarian Tumours Secondary to Carcinoma of the Stomach, by Mr. FAVELL.

SHEFFIELD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 10th, Mr. George Wilkinson, the President, being in the chair.—Dr. Arthur J. Hall read a paper entitled "Some Remarks on Intracranial Tumours." He referred to the clinical differences between tumours as understood when affecting other parts of the body

and intracranial tumours. Whereas the varying importance of different tumours in the body generally depends upon their histological structure—namely, whether they are malignant or innocent—such a distinction is of much less importance with intracranial tumours. The mechanical factors of a closed, practically non-expansile box, and a delicate, easily compressed, and in many parts vital, organ already filling the box play so large a part that a tumour innocent histologically, and small as tumours go, may yet prove as fatal within the cranium as if it were malignant. As the trouble is due to increased intracranial pressure one may include clinically with tumours such different pathological entities as tuberculous foci, gummata, cysts, including chronic local serous meningitis, abscesses, aneurysms, and even hæmorrhages. And although it probably never happens that an ordinary cerebral hæmorrhage is wrongly diagnosed as a tumour, yet the converse is often true—a tumour with sudden hemiplegic onset being diagnosed as merely a cerebral hæmorrhage. As regards treatment, the only drug of any benefit is iodide of potassium, and this should always be given early and fully, whether there is or is not a specific history, for it is always possible that there may be a gumma present when no other symptoms of the disease have at any time presented themselves, and it is absolutely latent. Also other conditions such as chronic serous meningitis may improve temporarily, even to a remarkable extent, under the drug, and lastly, other unexplained cases ("pseudo-tumours"), apparently showing all the symptoms of intracranial tumours, have benefited or disappeared. It must be remembered before urging operation that there are cases of tuberculous foci which improve instead of getting worse owing to their gradual shrinking, and also that there are cases of slowly developing tumour, such as osteo-fibroma, which may remain practically quiescent for many years. As regards operation, in spite of many difficulties and failures, yet the occasional brilliant result obtained and the desperate nature of the disease make every careful effort at localisation and removal not only warranted but to be strongly urged. These two points—viz., the great suffering in a progressive case when left to itself and the occasionally brilliant results of operation even in apparently hopeless cases—should be constantly and repeatedly impressed upon our minds. As regards symptoms, reference was made to the occasional but very rare complete absence of headache throughout. The paper was illustrated by a large series of lantern slides prepared from photographs of specimens in the Pathological Museum of the University of Sheffield, and concluded with a description of two cases of tumour of the third ventricle causing sudden death.—Professor J. M. Beattie read a paper on Further Experiments with a Streptococcus isolated from cases of Acute Rheumatism. The paper dealt with the results of intraperitoneal and intravenous injections of cultures of this streptococcus in rabbits, and was illustrated by numerous statistical slides.

MEDICO-CHIRURGICAL SOCIETY OF GLASGOW.—A meeting of this society was held on March 18th, Professor R. Stockman being in the chair.—Dr. Oscar Kraus (Carlsbad) read a paper on the Examination of Fæces in Medical Practice, which we intend to publish shortly.—Dr. J. M. Renton read notes on Some Cystoscopic Cases. In Case 1, a woman, aged 27 years, with tuberculous disease of the right kidney, cystoscopic examination after the injection intramuscularly of a solution of indigo-carmine showed that only this kidney was functioning, the other having been probably destroyed by antecedent disease. Treatment with tubercular vaccine was successful. In Case 2, a woman, aged 34 years, with a streptococcal pyelitis, the cystoscopic examination determined that the left kidney was the seat of disease. Incision of the kidney and drainage led to recovery. In Case 3, a man, aged 29 years, stone in the bladder had been diagnosed. The cystoscope showed merely a chronic cystitis, which bacterial examination proved to be gonorrhœal. Case 4, a woman, aged 35 years, presented symptoms of vesical calculus, but the sound failed to reveal a stone. With the cystoscope a small uric acid stone was seen lodged on a shelf of granulations. This was extracted per urethram. In Case 5, a man, aged 63 years, symptoms pointed to prostatic enlargement, though no enlargement could be felt. Cystoscopic examination showed a marked intravesical projection of the prostate. Suprapubic prostatectomy was performed with a good result. Case 6, a woman, aged 50 years, had painless hæmaturia intermittently for three or four years. Cystoscopic examination revealed large numbers of small warty papillomata, which the microscope showed to be simple in character. By suprapubic operation as many as possible were removed. Nine months later bleeding recurred and the operation was repeated. Since then eight months have passed without bleeding, but the cystoscope still showed a considerable number of papillomata.—Dr. G. A. Allan read notes on cases illustrating the Effects of Temporary and Permanent Closure of the Cerebral Arteries. In one case, the subject of mitral stenosis, there were recurrent attacks of paralysis without loss of consciousness or of sensation. Sometimes the paralysis affected only the arm, at times the arm and leg of the same side, or sometimes a hemiplegia was noticed. The recovery after an attack, which usually lasted from 15 to 30 minutes, was always complete. The condition was known to have been in existence for at least three years. A second case had transient loss of memory lasting for 18 hours, events which occurred during that period being lost to the patient's consciousness. This case had a slightly high-tension pulse, but no evidence of organic disease. A third case developed loss of speech and paralysis of an arm a few weeks after labour. She was also the subject of a mitral valvular lesion. Later, paralysis developed in all four limbs and in the face. She became blind and gangrene occurred in several of the finger tips, the nose, ears, and other sites. The patient died two months later.—Dr. G. Haswell Wilson described the post-mortem findings. Thrombosis was found in the arterioles of the brain causing cortical necrosis, and in the peripheral arterioles where gangrene had developed. At the same time there was an entire absence of any local disease of the vessel wall to account for the thrombosis. The cases were ascribed to angiospasm, in view of the transient nature of the attack and the complete recovery in the first cases, and on account of the absence of lesion in the arterioles in the last.

UNITED SERVICES MEDICAL SOCIETY.—At the March meeting of this society, which was held at the Royal Army Medical College, the President, Surgeon-General A. M. Branfoot, C.I.E., I.M.S. (retired), being in the chair, Staff-Surgeon H. C. Adams, R.N., read a paper entitled "Treatment of Syphilis by Intramuscular Injection of Metallic Mercury: Notes on Mercurial Creams," in which a plea was put forward for a uniform method of treatment of syphilis in the Navy by the intramuscular injection of metallic mercury. It was stated that this method was the most generally reliable because it was extremely difficult to induce men to carry out a prolonged treatment by the ingestion method owing to (1) traditional objection to taking mercurial pills; and (2) men neglecting to continue their visits to the sick bay when they had no active reminder of their disease. By the intramuscular method a weekly visit only was necessary, the medical officer had absolute control as to dosage, and also digestive trouble was obviated. Inunction was obviously impossible for the Service afloat. A short history of the use of mercurial creams in the Navy was given, the various formulæ which have from time to time been adopted were described, and the essential points for an ideal cream were discussed, statements being supported by a series of samples and microphotographs of cream, which showed that the main points in an ideal cream were: (1) the mercury must be in an extremely fine state of subdivision; (2) the basis should be sufficiently fluid at ordinary temperature to work freely in the syringe and needle but sufficiently viscid to suspend the metal; and (3) there should be no abrupt transition on warming from the fairly solid to the liquid state. As the result of various experiments the following formula appeared to the author to be most generally useful: Mercury, by weight, 20 parts; anhydrous lanolin, by weight, 30 parts; chlor-butol, by weight, 2 parts; liquid paraffin to 100 by measure, the cream containing 1 grain of mercury in $\mathfrak{m}$ v. A special all-glass syringe was shown fitted with a needle entirely of steel, including the socket, the use of platino-iridium needles having been abandoned because of their liability to leak along the seam. A short account of the technique was given showing that complications in this method can be obviated by attending to the following points: (1) absolute sterility of needles and materials; (2) choice of suitable site; (3) introduction of the needle at right angles to the skin well into the muscles, detaching the syringe from the needle to make sure that no blood-vessel has been entered; (4) keeping the needle

track perfectly clear of cream by ensuring that the eye of the needle is free from cream before introduction and waiting for a second after injection before withdrawing the needle.—An interesting discussion followed, in which Colonel F. J. Lambkin, R.A.M.C., Major A. P. Blenkinsop, R.A.M.C., Major C. E. Pollock, R.A.M.C., Fleet-Surgeon L. Bidwell, R.N., and Captain L. W. Harrison, R.A.M.C., joined, and the proceedings terminated with a hearty vote of thanks to Staff-Surgeon Adams.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 16th, Dr. A. Fulton, the President, being in the chair.—Dr. J. Watson and Mr. T. Burnie showed a patient with Moveable Kidney and Nerve Symptoms simulating Disseminated Sclerosis.—The discussion on the case favoured treatment by fixation of the kidney.—Dr. Watson showed several interesting Pathological Specimens.—Dr. A. Stanley Green opened a discussion on the Treatment of Gastric and Duodenal Ulcers without operation. Duodenal ulcer, owing to the care with which its symptoms had lately been taught, was now more frequently diagnosed. He could find no explanation why duodenal ulceration was so much more common in the male. These ulcers, too, became much more chronic in the male, because a man had neither the patience nor the time to complete his cure that a woman had. Among the exciting causes of ulceration were anæmia, oral sepsis, the bolting of food, and especially the hurrying off to business immediately after meals. Worry was a potent cause of recurrence, and he was inclined to look upon hereditary influence as playing a great part in alimentary ulceration. Hæmatemesis was a common symptom, but nevertheless in many cases all symptoms lay latent and perforation was the first sign of any ulceration. The immediate dangers were perforation and hæmorrhage, while the remote were pyloric obstruction, hour-glass constriction, adhesions about the bile-ducts, and cancer. Although many practitioners recommended operation as soon as the diagnosis was established, Dr. Green himself was inclined to advise this only as a last resource. He generally put his patients on a very strict diet for three months, commencing in bad cases with albumin water for the first 48 hours, and by gradual steps bringing the patient to a fairly generous diet at the end of three months, giving at the same time a mixture of bismuth and morphia with papain. Bread he found to be tolerated very badly; he had not found rectal feeding necessary.—Dr. C. H. Cattle's experience taught him that surgical treatment was generally necessary owing to the tendency to relapse.—In supporting this view, Mr. W. M. Willis pointed out how frequently old healed ulcers led to pyloric obstruction. Gastro-enterostomy afforded the only complete relief.—Mr. A. R. Anderson mentioned two cases of severe hæmorrhage from duodenal ulceration, which had completely recovered on medical treatment. He only advised operative treatment where medical treatment had failed.—Dr. J. F. Blurton, Dr. W. Hunter, and others also spoke in the discussion.

BRADFORD MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on March 15th, Dr. W. Ward-Smith being in the chair.—Dr. A. C. F. Rabagliati read notes on a case of Acute Appendicitis with special reference to causation.—Dr. Ward-Smith showed two cases of Paralysis.—Dr. T. Jason Wood showed a case after operation for Undescended Testicle.—Dr. A. Little exhibited "Kryptop" spectacles.—Mr. F. W. Goyder showed a specimen of Tuberculous Disease of the Third Rib with reference to its symptoms and treatment.—Dr. H. J. Campbell read a paper on Hypnotics. After a few preliminary remarks on natural sleep and the theories regarding it, the most rational of which supposed that the processes of the nerve cells of the higher centres are retracted during sleep, with resulting separation of their arborisations forming a series of blocks to the ready passage of impulses, Dr. Campbell said that hypnotics may be divided into three groups according to their mode of action—namely, (1) bromides; (2) chloral, sulphones, and urethanes; and (3) opium and its allies. 1. Bromides act in two ways: (*a*) as salines, raising the specific gravity of the blood, causing a rise in blood pressure and diuresis; and (*b*) as a depressant to the cells of the central nervous system. Bromides are chiefly of value in cases likely to be prolonged and where there is not likely to be any great call upon the brain for mental activity. 2. Chloral, sulphones, and urethanes have the following points in common: (*a*) power of diffusion into the uninjured cells of the living tissue; (*b*) comparative insolubility in water; (*c*) solubility in fat-like compounds such as brain lipoid; (*d*) no action upon the nerve cells; and (*e*) physiological action with some relationship to chemical constitution. After discussing the various actions of individual members of this group, Dr. Campbell passed on to Group (3) opiates, which depress the sensory nerve cells in the higher centres and also the nerve cells in the sympathetic ganglia. The action of opium was then discussed in detail, and a few words were said about atropine and hyoscine.

Reviews and Notices of Books.

Gegenbaur's Lehrbuch der Anatomie des Menschen. Von M. FÜRBRINGER, O. Ö. Professor der Anatomie, Universität Heidelberg. Erster Band. Mit 276 zum theil farbigen Figuren. Eighth edition. Leipzig: Verlag von Wilhelm Engelmann. 1909. Pp. 689. Price, paper, M. 18; bound, M. 20.50.

THE seventh edition of Gegenbaur's well-known work appeared in 1898, and this, the first volume of the eighth edition, is edited by Professor Fürbringer. The whole work will consist of three volumes. This volume begins with the history of anatomy, and then follow the cellular elements of the body and cell theories, a short account of development, the histology of the tissues, and a general view of the body and its component organs.

The introductory chapter, extending to over 60 pages, contains a most instructive and readable account of the history of anatomy from the ancient Greek period onwards, of the views of Aristotle and the Alexandrian school. Some of the oldest nomenclature comes from this period, and the history of early technical terms is given. Then follow the anatomy of the Middle Ages and the birth or, as it is called, the "Restoration" of anatomy in Italy. This is the brilliant period associated with the names of Sylvius of Paris, Vesalius, Berengar of Carpi, Calcar, Dryander, Mundinus, Eustachius, Fallopius of Modena, Lancisius, Columbus of Cremona, Vidius of Florence and later of the Collège de France (Paris), Botalto, Fabricius, Aranzio, Casserius, Spigelius, and others. Then we come to the progress of the seventeenth and eighteenth centuries, and the period of William Harvey, Vesling of Padua, Riolan, Pecquet of Dieppe and Montpellier, Steno, Lower, Vieussens of Montpellier, Aselli of Pavia, Wirsung, Wharton, Bartholinus, Peyer of Schaffhausen, Brunner of Heidelberg, Willis of Oxford, Borelli of Pisa, de Graaf of Delft, Pacchioni of Rome, Valsalva of Bologna, Santorini of Venice, Poupart of Paris, Douglas, Thebesius, Vater, Winslow, and others, nearly all of whom have their names associated with some part of the human frame. Nor must we forget Swammerdam of Leyden (1627–80), and the linendraper of Delft, Leeuwenhoek (1632–1732), and Malpighi. New impulses came from France through Vicq d'Azyrs, and above all through Bichat (1775 1802). The story is continued down the century, and a most readable account it is. There is appended an excellent bibliography.

The real work begins with the "cell doctrine," or cytology, to which nearly one hundred pages are devoted. The illustrations are both numerous and excellent, and the text deals with cells in their varied relations, structure, and capacities both in man and animals. Then follows a chapter on development, or ontogeny, of nearly two hundred pages. It is, in fact, a treatise in itself on embryology. The schema of development of the spermatozoa in colour is excellent, and so is that of the germ cells. The early changes in the embryo are very fully discussed and well illustrated, and,

as in other sections of the work, there is appended an excellent and useful bibliography.

The third section, on Histology of the Tissues, runs to nearly two hundred pages, and deals with the "Vegetative" and "Animal" tissues. Under the former title is included epithelial and connective tissue, and under the latter muscle and nerve are dealt with, and the relation of the one to the other. The whole section is very well done, and it is profusely illustrated; the nerve endings are very fully described.

In the fourth and last section, which is shorter than the others, we have a general account of the organs and systems of the body and their relative proportions in the adult and during growth. Then the body is treated as a whole, from the point of view of weight, specific gravity, volume, differences due to sex and age; the stages of infancy, puberty and adolescence, and old age, or, as the author terms them, infantia, juvenilitas, virilitas, and senium; and then there follow symmetry of the body and righthandedness. There is appended a very complete index.

We can strongly recommend this work to the attention of anatomists. Professor Fürbringer has worthily carried out the traditions of his great chief and master in anatomy—Gegenbaur.

Inflammation: An Introduction to the Study of Pathology. Being the reprint (revised and enlarged) of an article in Allbutt and Rolleston's "System of Medicine," by J. GEORGE ADAMI, M.A., M.D. Cantab., F.R.S., sometime Fellow of Jesus College, Cambridge; Professor of Pathology, McGill University, Montreal. London: Macmillan and Co. 1909. Pp. 254. Price 5*s.*

Professor Adami's well-known article on Inflammation has become a medical classic, and the publishers have been well advised to publish it separately as a book on the subject, a fact which the appearance of this, the fourth, edition demonstrates. "A knowledge of the inflammatory process is the foundation of all pathology" is an aphorism with which few would venture to disagree. One of the great merits of Professor Adami's treatment of the subject is the admirably lucid manner in which he develops the conception of inflammation as a reactive process rather than as a state. The interesting comparative study of the reaction to injury, from its simplest form in the Protista to its most complex varieties in the vascular tissues of the vertebrata, renders this book most readable as well as instructive.

A detailed analysis of the subject matter is unnecessary in regard to a work so well known, but we may refer briefly to the additions made in this edition so as to bring it as far as possible abreast of recent work. There is an account of the interesting observations of Opie, who has demonstrated the existence of two proteolytic enzymes in the exudate set up by a non-bacterial irritant—viz., turpentine—one being effective in a weakly alkaline medium, the other in the presence of acid. He has further discovered that in the serum of the exudate there may exist an "anti-enzyme" tending to arrest the activity of these ferments. Professor Adami points out that these observations suggest that it is not always wise to perform complete paracentesis in serous effusions, since the loss of the anti-enzyme which they contain appears to entail a greater tendency to suppuration. The work of Bail on bacterial aggression is also discussed. Some years ago both Dr. Ainley Walker and Professor W. H. Welch suggested it was probable that microbes would be stimulated to produce antibodies to combat the protective processes of the body. Bail has demonstrated the existence of such substances, to which he has given the name of "aggressins." They appear to paralyse the protective agencies of the body, so that when given with a sublethal dose of a pathogenic organism they render it lethal. The phenomena of chemiotaxis are discussed at some length in the light of recent work, which tends to explain them upon physical grounds as depending upon changes in the surface-tension in the leucocyte secondary to changes in its constituent molecules, these being brought about by alterations in its fluid environment. The work of Professor J. M. Beattie and Dr. W. E. C. Dixon on the newly-formed capillaries of granulation tissue is referred to. These observers found a primary formation of new capillaries well developed in an incised wound 24 to 36 hours after its infliction, but that these capillaries tend to disappear, being replaced by a second better supported set of new capillaries. Some observations of Carrol upon the effects of replacing a length of artery by a length of vein from the same animal, whereby a marked fibrosis of the latter results, are quoted as supporting Professor Adami's view that there exists a functional hypertrophy of connective tissue which is to be differentiated from an inflammatory overgrowth. Sir Almroth Wright's work on the opsonins is also incorporated and applied to the explanation of some of the phenomena of the inflammatory reaction. Professor Adami sums up his conception of inflammation in the following words: "It is the series of changes constituting the local manifestation of the attempt at repair of actual or referred injury to a part, or briefly, as the local attempt at repair of actual or referred injury."

This book will doubtless survive to several more editions, but we may perhaps express the hope that Professor Adami will see his way to retain the charming preface to the third edition.

Lectures on the Use of Massage and Early Movement in Recent Fractures and other Common Surgical Injuries, Sprains and their Consequences, Rigidity of the Spine, and the Management of Stiff Joints generally. By Sir WILLIAM H. BENNETT, K.C.V.O., F.R.C.S. Eng., Consulting Surgeon to St. George's Hospital and to the Hospital of St. John and St. Elizabeth, and Senior Surgeon to the Seamen's Hospital, Greenwich, &c. Fourth edition. With 23 illustrations. London: Longmans, Green, and Co. Pp. 134. Price 6*s.*

THE credit of recommending in recent fractures the use of massage and early movement belongs primarily to Lucas-Championnière, who has advocated this method of treatment for many years, in spite of the hesitation with which it was received by the great body of the profession and the little amount of imitation with which it was followed. To Sir William Bennett belongs the credit of introducing into this country the methods devised by the French surgeon. Those who compare the attitude of the profession towards the method at the present time with that adopted even a few years ago will not hesitate to acknowledge that this mode of dealing with recent fractures has not only progressed greatly in the extent to which it has been employed in practice, but also in the value of the results which have been obtained.

When Sir William Bennett first brought forward the method it was imagined that he was advocating its employment to the exclusion of the use of splints or of operation where it is usually considered to be needed, but this impression was entirely erroneous. He merely urged, though he urged strongly, that fair consideration should be extended to a plan of treatment which if used discreetly as an adjunct to the methods ordinarily employed, and if modified as circumstances might demand, had been found to be satisfactory in theory and advantageous in practice. The fact that this book has reached the fourth edition, though its first appearance was in 1900, is sufficient proof in itself that there was need for it, and that it has fulfilled the purpose for which it was issued. We have on other occasions expressed our approval of the methods of early movement and massage in fractures, and we are glad to see that this temperate exposition of the principles and practice of the methods has met with so cordial a reception at the hands of the medical men of this

country. It cannot be said that all the details of this mode of treatment are even yet fully established. Progress will undoubtedly be made in the future and every surgeon's personal experience will aid him in devising new modes of application of the method.

Sir William Bennett, after giving a general description, discusses the application of massage and movements to certain special fractures, and he applies these modes of treatment also to dislocations and sprains. The lecture dealing with "Sprains and their Consequences" is especially valuable, for only too often the results of these injuries are unsatisfactory both to the surgeon and to the patient. We would like to commend also the chapter on stiffness of the spine, a condition often proving very puzzling to those who have not specially considered the matter. A valuable collection of skiagrams illustrates the work well.

Manual of Operative Surgery. By JOHN FAIRBAIRN BINNIE, A.M., C.M. Aberd., Professor of Surgery, Kansas State University, &c. Vol. I.: Operations on the Head, Neck, Nerves, Trunk, and Genito-urinary System. Fourth edition, revised and enlarged. With 713 illustrations, many of which are in colours. London: H. K. Lewis. 1909. Pp. 832. Price 14*s.* net.

THE cordial welcome which we extended to previous issues of this book is equally deserved by the present issue. We pointed out when speaking of the first edition that the book was chiefly remarkable for the care shown by the author in confining his account to the most modern surgery, and especially to those methods which have been introduced within recent years. The concentration of the work, despite its inevitable growth, and the rejection of unnecessary verbiage facilitate greatly the use of the volume by those for whom it is really intended—namely, operating surgeons. It is not suited for those whose knowledge of surgery is small, but it must prove of genuine value to those surgeons who wish to see, as it were at a glance, the most modern methods of dealing with disease by operation. The natural tendency of all successful books is to grow, and this exhibits that tendency in a marked degree, for the book before us is only half of the whole work, and yet it is as large as, or even larger than, the volume which formed the first edition. The more carefully the book is examined the greater is the appreciation of the reader at the large amount of material which has been compressed into it. It is safe to say that the work contains more than many volumes of far greater size, and the manner in which it is written has helped to achieve for it the success which it deserves.

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India. No. 29. Piroplasma Canis and its Life Cycle in the Tick. By Captain S. R. CHRISTOPHERS, M.B. Vict., I.M.S. Calcutta: Office of the Superintendent of Government Printing, India. Price 2 rupees, or 3*s.*

IN his introduction to this monograph the author first gives us the historical data with reference to the piroplasmata, showing their relationship to Texas fever, red-water, tropical piroplasmosis of cattle, that of dogs, horses, monkeys, mules, sheep, goats, asses, and rats. "Heart water" at the Cape is probably also caused by a piroplasma. Naturally the transmission of piroplasmosis takes place by ticks; how this was effected was shown by Smith and Kilborne, who proved that the southern cattle of the United States communicated it to the northern cattle through the bite of the young brood of infected ticks. Subsequently it became clear from the observation of others that the piroplasmata behave differently as regard the exact mechanism of their transmission, either in the case of different species of parasite or when transmitted by different species of ticks, various types of transmission being noticeable. Captain S. R. Christophers describes afresh the piroplasma canis, and gives the complete life-cycle of the parasite both in its mammalian host and in the tick. He first gives the geographical distribution, then the symptomatology, the pathological changes, the morphology of the parasite, and the progress of infection, with examples of casts. He then describes the transmission of piroplasma by ticks, with the general life-history of the latter, after which the facts relating to experimental infection are detailed. Finally, we find an account of the developmental cycle of piroplasma canis in the tick. A valuable bibliography of the subject appropriately closes this interesting Memoir. The work is illustrated by some clearly-drawn plates.

LIBRARY TABLE.

Handbook of Diseases of the Ear. By RICHARD LAKE, F.R.C.S. Eng. Third edition, with 56 illustrations and 4 coloured plates. London: Baillière, Tindall, and Cox. Pp. xii.–248. Price 7*s.* 6*d.* net.—We are glad to see the third edition of this little handbook. It has been thoroughly revised and brought up to date, and without going into an excess of detail it gives a very clear and concise account of the otology of to-day. In comparison with the second edition we notice many changes, most marked, perhaps, in Chapter X., on operations. Here three new illustrations have been added explanatory of the radical mastoid operation, and the letterpress contains additions in the shape of a short account of Kuster's modified mastoid operation and operative procedures on the labyrinth, illustrated by figures. Oto-sclerosis has been given a chapter to itself. In Chapter XIII. there has been appended a short and clear account of the caloric and rotation tests with their significance. An extra coloured plate, "Tympanic Membranes: Pathological Conditions," has been added to those in the previous edition. We notice that Mr. Lake in Chapter VIII. on Chronic Suppurative Disease of the Middle Ear at p. 149 makes the following statement in connexion with the treatment of aural polypi: "It is always well to remember that in soft pedunculated polypi a vigorous use of the syringe will not infrequently rupture the connexion of the growth." This seems to us rather a dangerous advocacy of the aural syringe. We should like to have seen a chapter on the physiology of hearing added after that on the anatomy of the ear, and another on the bacteriology and cytology of aural suppuration. These would have undoubtedly increased the value of this excellent little work, and the next edition will give Mr. Lake his opportunity.

Preventable Diseases. By WOODS HUTCHINSON, A.M., M.D. London: Constable and Co., Limited; Boston and New York: Houghton Mifflin Co. 1909. Pp. 442. Price 6*s.* net.—This is an excellently written and instructive book, apparently designed for the use of the educated layman. And when we say this we in no way mean to suggest that it is a book of "home treatment," for it impresses upon the layman the necessity for sending for a medical practitioner when he is ill. The whole teaching of the work is altruistic from the medical point of view in that it shows how the public may avoid being attacked by the more common forms of disease. Incidentally the matter contained in the book is a perpetual reminder of the fact noted with regard to malaria on p. 296—namely: "There is no such thing as useless or unpractical knowledge. The only thing that makes any knowledge unpractical is our more or less temporary ignorance of how to apply it." Dr. Hutchinson writes in an easy and popular style and his remarks are put in such a way as to make them easy to grasp and to remember. For instance, the informing

chapter on "colds" is headed, "Colds, and How to Catch them," the chapter itself being an excellent discourse upon "colds" and how they may be avoided. The first chapter, called "The Body Republic and its Defence," is as good a description of a singularly complex subject, written for the understanding of the people, as we have ever seen.

Clinical Studies for Nurses. By CHARLOTTE A. AIKENS. London and Philadelphia: W. B. Saunders Company. 1909. Pp. 510. Price 10*s.* net.—We reviewed recently Miss Aiken's "Primary Studies for Nurses," and much that we said of that book is applicable to this, its successor. There is the same uncertainty as to whether the book is meant for the teacher or for the taught. It is not exactly a handbook of nursing, neither is it a primer of medicine, but it is too medical for the former and too superficial for the latter. Nursing details when they are given are good, and we are thoroughly in accordance with most of the following statements on p. 326 dealing with diseases of the eye: "It is important for a nurse to know something of the common diseases of the eye and the disastrous consequence of neglect of them, but it is still more important in connexion with this lesson, that she be able to demonstrate her ability to perform properly the nursing duties in connexion with such patients. No examination or quizzing on the theory of this subject is half as important as an hour spent in testing the nurse's ability to properly evert an eye, administer eye drops and lotions, irrigate the eye thoroughly ....." Except for the carelessness of stating that it is a nurse's duty to evert an eye, instead of an eyelid, this passage is commendable. But the book is very unequal and stands in need of revision. On p. 352, in the directions for poisoning, no warning is given against administering emetics in cases of corrosive poisoning. The price of the work, which is high, might have been reduced by leaving out a number of the illustrations, many of which are useless.

Nisbet's Medical Directory, 1910. London: James Nisbet and Co., Limited. Pp. 802. Price 7*s.* 6*d.*—The present issue is the third annual one of this useful publication. Like former issues, the directory is divided into two parts, Part I. giving the names of practitioners arranged alphabetically without reference to place of residence, and Part II. being a local directory in which the names of practitioners are given under their respective places of residence. These places are arranged alphabetically without reference to geographical position. Thus we find Bolton-on-Dearne, Bombala, N.S.W., and Bombay in consecutive order, which affords a very striking proof of the ubiquity of British medicine. The book is well printed, and from practical experience we know it to be carefully compiled. It is a useful and handy work. It neither gives, nor pretends to give, all the information contained in the larger and older directory. The only drawback that we have found to its use is when referring to a widely-held surname when the initials of the individual required are unknown. Thus the aggregation of all the "Smiths" and "Macs" in one part of the book makes individual identification tedious in a way that does not apply to a work which distributes each group of "Smiths" or "Macs" in territorial sections. But the plan of the book prevents this difficulty from being avoided, and has many compensating advantages, notably its simplicity.

London Pride and London Shame. By L. COPE CORNFORD. London: P. S. King and Son. 1910. Pp. 174. Price 6*s.* net.—This is a collection of sketches which have appeared in various leading London papers. To say that they are journalism is no disparagement, for they are high-class journalism, and few attain to a high standard in this branch of literature. It is not given to everyone to realise at a glance, in a few minutes, the technical difficulties of the pursuits of other men, in which the observer has had no training himself, to conceive the mental and physical powers necessary for their proper performance, and to present the result of his observations in a form free from sentiment and the use of excessive phrase. Mr. Cornford can do all this. We like many of these articles, especially that on football and on yacht racing, though obviously the writer knows nothing of either sport, and admits the impeachment. But honestly the best sketch in the collection is that of a surgical operation, and of that we may claim to judge. The description of the "*mise en scène*" is admirable, but the grasp of the moral factors is better. "..... In this clean white shrine, in which the surgeon is about to pit his skill and science and tried resolution against no less an enemy than death himself, there is perfect quiet and absolute order. There are no instructions issued, there is no need for them. The forces are drilled to perfection. ..... He is perfectly cool and unhurried, and every deft manipulation is characterised by the same unfaltering decision. The various instruments which he requires seem to arise in his hand like magic. There is hardly any effusion of blood. No one says anything at all. The nurses beside the glass tables are all quietly busy, handing this, receiving that, exactly at the right moment." The rest of the account of the operation is better still. Would that the outsiders who occasionally stray in to watch and describe surgical work could do such good justice to the discipline, the intense care, and application which the work demands.

Operative Nursing and Technique: a Book for Nurses, Dressers, House Surgeons, &c. By CHARLES P. CHILDE, B.A., F.R.C.S. Eng., Senior Surgeon, Royal Portsmouth Hospital. London: Baillière, Tindall, and Cox. 1909. Pp. 224. Price 4*s.* net.—The success of modern surgical operations does not depend on the surgeon alone; the intelligence, knowledge, skill, and assiduity of his assistants are almost equally important if the operation is to have the results desired. It is by constant training only that a nurse or house surgeon can be brought to appreciate the importance of the essentials of modern aseptic surgery. The modes in which carelessness or ignorance may lead to a surgical disaster are so many that the greatest trouble in seeing that the assistants know what they have to do and why they have to do it is not mis-spent. On the broad general principles of modern surgery almost all surgeons are agreed. As to the details, there are innumerable differences depending partly on the medical school at which the surgeon was trained and partly on his own personal experience. Therefore we cannot expect uniformity in these minor matters, but neither do we desire it. Progress itself depends on an intelligent application of the general principles and not on the slavish adhesion to individual methods. Mr. Childe has compiled a useful little book which is mainly intended for the use of nurses, though much that it contains is likely to be valuable to students and house surgeons, or even perhaps to surgeons themselves. The nurse is first instructed in the theory of sepsis, antisepsis, and asepsis. Then follows an account of the treatment which it is desirable should be followed in preparing a patient for operation. The next chapter deals with the preparation of the theatre and of the materials and instruments employed. The duties of the theatre sister, nurses, and porters are described. What has to be done when the patient returns to the wards after operation is also detailed, as well as the whole after-treatment and the after-treatment of various complications. The chapters on the

selection of instruments for various operations are well illustrated, and a valuable section is devoted to an account of operation in surgical homes and private houses. There are details in which we may differ from the author, but the directions given by Mr. Childe are always reasonable.

The New Third Appendix to Squire's Pocket Companion. London: Squire and Sons. 1910. Pp. 160.—This little book marks the third of a series of appendices to Squire's Pocket Companion, and also brings up to date the recently published eighteenth edition of the larger Squire's Companion. The first appendix was issued in 1905 and the second in 1906, the third bearing the date of the current year. These appendices have now become a fixed feature of Squire's literary productions, and we believe that a regular demand has been established for them from all parts of the world. They are published primarily in the interests of the medical profession, to whom they are supplied gratis on application. As the matter which they contain is supplementary also to the two books named above they are also sent gratis on application to all who have purchased either the one book or the other. The third appendix is a brief but concise review of the progress of therapeutics and pharmacy from 1908 to 1910. The complete and exhaustive review from 1899 to 1908 is to be found in the eighteenth edition of Squire's Companion to the British Pharmacopœia (published by J. and A. Churchill, price 14*s.* net; post free, 14*s.* 6*d.*). This appendix, like the second appendix, contains three sections, A, B, and C. Section A is devoted to the review of therapeutics and pharmacy, and contains amongst other items of general interest monographs on arsacetin, atoxyl, calcium lactate, mercury atoxylate, novocaine, and paraphenylenediamine. Several of the abstracts of the latest pharmaceutical literature are very interesting, notably one on quinine sulphate, which contains references to the papers read before the Seventh International Congress of Applied Chemistry on the Standards for the Purity of Quinine Compounds, and one on Stovaine, which embraces Dr. Jonnesco's recent improvement in the methods of producing general spinal anæsthesia. Section B deals with the more important of the special pharmaceutical preparations which have been introduced by Squire and Sons to meet the convenience of members of the medical and surgical professions desirous of prescribing in an elegant form some of the drugs mentioned in the therapeutical and pharmaceutical review in the first section. Section C is introduced with the object of giving, in a readily available form, items of information which should be useful to medical men. The subject of solubility is dealt with as thoroughly as the space available will allow. Tables of the solubilities of official and not official substances are given, and the article on Chemical Standardisation of Drugs, which appears in the first section, is here supplemented by a tabulated comparison of the chief standardised potent preparations of the British, French, German, and United States Pharmacopœias. This table has been compiled from the tables in Squire's Companion, eighteenth edition, and the paper on the Standardisation of Potent Drugs and International Agreement with regard to it by Squire and Caines, which was read at the Seventh International Congress of Applied Chemistry. Tables of weights and measures, and a comparison of the metric and imperial weights and measures are also included, and with an authoritative article on standardisation make up a thoroughly valuable little book.

THE Paris Academy of Medicine has elected M. Lucet to be a member and M. Delagénière of Mans and M. Monprofit of Angers to be corresponding members.

JOURNALS AND MAGAZINES.

The Journal of Physiology. Edited by J. N. LANGLEY, Sc.D., F.R.S. Vol. XXXIX., No. 6. London: Cambridge University Press. March 8th, 1910. Price 7*s.*—The contents of this number of the *Journal of Physiology* are: 1. Some New Forms of Apparatus for the Analysis of the Gases of the Blood by the Chemical Method, by T. G. Brodie, M.D., F.R.S., from the Physiological Laboratories of the London School of Medicine for Women and the Brown Institution, University of London. 2. On the Relation between the Physical, Chemical, and Electrical Properties of the Nerves: Part II., The Tissues Composing a Nerve Trunk, by F. O'B. Ellison, from the Physiological Laboratory of St. Mary's Hospital Medical School. The estimations were carried out on the medullated (median) and non-medullated (splenic) nerves of the horse. The sections were made from specimens embedded in celluloidin. The average percentage composition of the medullated nerve was found to be—connective tissue 63, medullary sheath 28, axis cylinder 9; of the non-medullated nerve—connective tissue 61, and nerve fibre 39 per cent. 3. On the Relation between the Physical, Chemical, and Electrical Properties of the Nerves: Part III., Total Ash, Sulphates, Phosphates, by N. H. Alcock, M.D., D.Sc., and G. Roche Lynch, from the Physiological Laboratory, St. Mary's Hospital Medical School. In the horse the ash of the median nerve is 0·985 per cent. of the original weight of the nerve; the sulphates, 0·0110 per cent.; and the phosphates, 0·768 per cent. The ash of the splenic nerve weighs 0·914 per cent.; the sulphates, 0·0646 per cent.; the phosphates, 0·349 per cent.; the ash of connective tissue, 0·549 per cent.; the sulphates, 0·0813 per cent.; and the phosphates, 0·0797 per cent. 4. The Nature of Oxyhæmoglobin, with a note on its Molecular Weight, by J. Barcroft, M.A., B.Sc., and A. V. Hill, B.A., scholar of Trinity College, Cambridge, from the Physiological Laboratory, Cambridge. The amount of heat given out when one gramme of hæmoglobin unites with oxygen is 1·35 calories. 5. Improvements in the Technique of Blood Gas Analysis, by Joseph Barcroft, M.A., B.Sc., and Ff. Roberts. 6. Contributions to the Physiology of Marine Invertebrates, by H. E. Roaf, M.D., M.Sc., University of Liverpool. Amongst the animals whose digestive fluids were investigated were Actinoloba dianthus, Echinus esculentus, Asterias rubens, Pecten opercularis. In all instances digestion appeared to commence in the presence of acidity which was subsequently exchanged for alkalinity. 7. The Oxygen Capacity of the Blood after Hæmorrhage, by C. Gordon Douglas, B.M., Oxford. 8. Quantitative Researches on the Summation of Inadequate Stimuli in Muscle and Nerve; with observations on the Time Factors in Electric Excitation, by Lucas Keith, Fellow of Trinity College, Cambridge, who shows that for each excitable tissue there is a characteristic time factor involved in excitation. This time factor varies with varying conditions of temperature and the nature of the salts in the surrounding fluids. 9. Cardiac Metabolism of Alcohol, by Philip Hamill. The author, who writes from the Pharmacological Laboratory, Cambridge, finds that the heart is capable of metabolising alcohol; he describes a method of estimating alcohol in dilute solutions. 10. Creatin Excretion in the Bird and its Significance, by D. Noel Paton, Physiological Department, University of Glasgow. Paton finds that in the urine of several birds—goose, duck, and hen—creatin takes the place of the creatinin of mammalian urine, and that as this is an end-product of avian muscle the amount excreted constitutes a measure of the muscle catabolised. This number also contains the

Proceedings of the Physiological Society for Dec. 11th, 1909, and the title-page and table of contents for Vol. XXXIX., 1909-10.

Social Diseases.—A new periodical with this title made its first appearance recently in the United States. It carries the sub-title "Report of Progress of the Movement for their Prevention." From the "foreword" of this first issue we learn that it is a tentative publication, to be repeated quarterly by one of the 13 societies organised in the United States for the purpose of preventing or limiting the spread of venereal diseases, and it has in view the federation of these local independent societies and the production of concerted action between them. It is likely that this project will take shape at the forthcoming meeting of the American Medical Association at St. Louis in June. The present issue of *Social Diseases* contains an address by Dr. Prince A. Morrow, well known as a pioneer in the movement, before the American Society of Social and Moral Prophylaxis, and papers by Dr. Daniel R. Hooker and Dr. Robert N. Willson. The aim of the whole may be summarised in the following phrases from Dr. Morrow's address: "More protection for young women who are too often made professionals through seduction, fraud, or force; less indulgence for the men who in robbing them of their virtue infect them with disease." And again: "Its object is not to make prostitution safe, but to prevent the making of prostitutes."

The Edinburgh Medical Journal.—In the March number Dr. John Robertson deals with the milk-supply of large towns, and points out that the chief reforms called for concern the premises of the producing farmers; and Mr. A. Forbes Mackay contributes some notes on health in the Antarctic region, treating of frost-bites and snow-blindness. A paper by Mr. William Guy, Dr. Alexander Goodall, and Dr. H. S. Reid on the blood pressure in anæsthesia, discusses the asphyxial element in gas narcosis, both with and without ethyl chloride; this undesirable factor can be prevented by previous inhalation of oxygen. Mr. W. G. Porter records some cases of laryngeal tumours and describes in detail his method of inducing local anæsthesia for their removal.

The Medical Chronicle.—A paper by Dr. D. P. D. Wilkie in the March issue of this journal deals with prophylactic measures against post-operative peritonitis. The writer concludes that the combined use of a vaccine of B. coli and of nucleic acid enhances the power of resistance to this affection, in which the organism named plays a leading part, and notes that there may be advantages in performing certain abdominal operations in two stages, since the first may stimulate reaction by the irritation produced, and so lessen the dangers of the second. Mr. D. Lindley Sewell writes on Bárány's tests for labyrinthine affections, which are carried out by means of stimuli inducing nystagmus. He considers their diagnostic value as proved in some cases, though it would be premature to give a definite opinion as to their trustworthiness.

The Birmingham Medical Review.—Recent issues of this review contain a series of papers on the sanatorium treatment of tuberculosis and the cases which are suitable for this procedure. It is interesting to note the degree of reliance apparently placed by all the writers in the doctrine of auto-inoculation. In the January number Mr. W. Duncan Lawrie emphasises the importance of the abdominal muscles in maintaining the health of the individual. He believes that chances of longevity are in inverse proportion to the girth of the abdomen, and advises the use of certain simple exercises to strengthen the muscles and improve the figure.

SIGHT-TESTING IN SCHOOLS.

A SUGGESTION FOR NEW TEST TYPES.

IN the schedule of medical inspection issued by the Board of Education it is stated that the testing of eyesight should be undertaken for the first time at the age of about six years. Owing to the fact that children do not come to school at so early an age as they used to, and that the teaching of reading is postponed to a later age, it will be found that when children 6 or 7 years old come up for medical inspection a certain proportion will find great difficulty in reading the ordinary Snellen's test-type cards. With many children who are merely backward a card devised as nearly as possible in accordance with the ordinary reading cards and type used in the schools will be found extremely useful.

Mr. W. Lloyd Edwards, school medical officer and deputy medical officer of health at Barry, Glamorgan, writes to us as follows: "As the object of the school medical officer is to test sight and not the reading powers of the child, the task should be made as easy as possible, as by so doing much valuable time will be saved. Children are first of all taught reading from small letters and not from capitals, whilst most test types consist of capitals only. Small letters (not capitals) should therefore be used for sight testing. It is also necessary to choose the letters which are best known to the children, avoiding the small b and d, which are so often mistaken for one another by children. The medical inspector or the nurse should also be familiar with the 'phonic' method of teaching reading, in which the child does not give the name of the letter but the sound value of the letter. The best letters for use on a Snellen's test type card such as I have indicated would be:—p, r, a, t, o, c, f, g, h, m, n. With regard to those children who are either mentally defective or who find a difficulty in knowing their letters Landholt's 'broken-ring' optotype is far preferable. Dr. Marcus Gunn[1] stated at the Toronto meeting of the British Medical Association that for the testing of the sights of recruits the use of Snellen's types has its disadvantages, and recommends the use of optotype. But to get the full value of the 'broken-ring' ring' some device for rotating the test card is to be recommended. The boys in the woodwork centres at the work and metal Barry Schools constructed a simple little apparatus which does well for this purpose. A wooden disc 7 inches in diameter is attached to a board with pulley intervening. The wooden disc has slots so as to carry 7 cards of the same diameter. Each of these cards has a 'broken ring' of the various sizes $\frac{6}{60}$ to $\frac{6}{6}$. The pulley by means of a cord is attached to a little crank handle. In this way it is possible to revolve the 'broken ring,' taking off each card when finished with and using a smaller one. The testing of types, therefore, can be made a kind of kindergarten occupation. The school medical officer of Tasmania modified the Landholt's optotype by giving 8 different positions of the 'broken ring' on the test type card instead of 4, but I think my plan is preferable.

"My ideas in these matters have been carried out for me by Messrs. F. Davidson and Co., Great Portland-street, London, and these devices will, I think, be found very useful for schools."

THE LANCET.

LONDON: SATURDAY, APRIL 2, 1910.

The Lessons of a Great Hospital.

THE history of a great hospital is in miniature the history of the medicine of the country to whose needs the charity ministers. In the foundation of a hospital we have a public recognition that the institution is needed. That recognition has been at first in most instances very small, but none the less the first receipt of public money is a formal acceptance by the public of the claims of the sick poor upon their healthier, and especially upon their more affluent, neighbours—claims which are enforced by common-sense no less than by loving-kindness. In the passage of the hospital through its various stages of development, in the growth of its buildings, in the more comprehensive nature of its services, and in the larger intimacy which it comes to enjoy with other eleemosynary work and with every conceivable scheme for social betterment,—in these things we have a public acknowledgment and a tangible proof that the science of medicine has become an integral part of the scheme of life in all its phases. This recognition, which is more sympathetic and more widely accorded in proportion as the State progresses in the march of civilisation, derives a new interest when the hospital affiliates to itself a medical school. The foundation of a medical school is a movement especially designed to accentuate the value of the relations between those who practise medicine and those who at all hours and in all ways call the service of medicine to their assistance.

"A skill in the practice of physic or surgery," said Sir WILLIAM BLIZARD, that veteran of the London Hospital who served the institution as surgeon for nearly 60 years and was joint founder of its medical school, "cannot be acquired without an attendance at an hospital. But that degree of skill which can be acquired from an attendance on hospital practice, without a proper knowledge of principles, as it is the result of mere imitation, must be comparatively very small. It is necessary, therefore, that principles be studied. But the principles of Medicine and Surgery cannot be taught but by means of lectures publicly read. The experience of learned men from the beginning of science to the present time has proved this to be the only true and effectual method of instruction. By means of these the several discoveries that have been made respecting any art or science are properly brought together and preserved, and new ones continually added, which otherwise might in time be lost and forgotten. But lectures on the principles and practice of Physic and Surgery cannot, consistently with the advantage of the student respecting his improvement, be properly given in any other place than the hospital which he attends."

The position of the lecture in the educational scheme is, of course, much altered since the days of Sir WILLIAM BLIZARD, and to him the word no doubt stood for the whole of the organised instruction which the student now receives at a medical school. He spoke the phrases which we have quoted more than 120 years ago, when physiology and pathology were in their infancy and when the only professional education which a medical student could possibly receive was through the medium of systematic lectures, the principles of which could be demonstrated by clinical examples in the wards. But what he says holds good to-day. It is impossible to divorce professional medical education from actual practice among the sick, and it is only in hospitals that the clinical facilities can be obtained. On the other hand, the benefits received at a large general hospital from the coöperation of a medical school are very real—a side of the question which too many people are ready to overlook.

The history of the London Hospital,[1] as set out in an interesting book which has just reached our hands, illustrates in a very apt manner these various points. Mr. E. W. MORRIS shows how the hospital had its origin in the charitable feeling of seven London citizens who were inspired by a medical man, JOHN HARRISON, and none of whom had any large fortune by means of which he could at once transform a great idea into a great actuality. The London Hospital was founded under the title of the London Infirmary, and had as its object the treatment of the sick poor of Aldgate and the adjoining riverside. The seven founders could give time, energy, and knowledge of the evils they wished to counteract, but they could give but little money. The date of the foundation, 1740, was a period of extreme sickness in London. The population of the metropolis at that date was about three-quarters of a million, but in 1740, over 30,000 persons died, of whom 4000 died from "fever" and 2725 from small-pox. An extremely severe winter aggravated the miseries of the sick poor, though in all probability it had a beneficent effect on the spread of typhus fever, while the price of wheat at Michaelmas being 56*s.* per quarter spelt semi-starvation for hundreds. The glaring misery produced by these conditions of hunger and epidemic disease stimulated HARRISON and his group of friends to some concerted action, however small, that should act as a remedy, however local and partial, and in the foundation of a dispensary they had before them successful examples set in three other quarters in London. So this small group of citizens met first in the "Feathers" tavern and then at the "Baptist's Head" tavern in Aldermanbury, and resolved to take a house "near the Dog Bar, for £16 per annum, with liberty to quit the same at six months' notice," and open an infirmary. Such was the beginning of the largest hospital in the metropolis, and when its pioneers met after taking the house, after paying £15 for furniture "for the doctor's, surgeon's, apothecary's, manager's, and patients' rooms," and after hiring a man and a woman as caretakers, there remained one shilling in the treasury. And now the hospital has 922 beds, its elaborately organised out-patient department is enormous, its special departments are as numerous as the needs of the public and the growth of science have nowadays and between them made necessary, it has a nurses' home and institute attached to it, and a large medical college. The two caretakers of "the house near the Dog Bar" are represented by a selected crowd, over one hundred in

[1] A History of the London Hospital. By E. W. Morris. London: Edward Arnold. 1910. Pp. 296. Price 6*s.* net.

number, of receiving-room officers, resident accoucheurs, house physicians, house surgeons, clerks and dressers, as well as a veritable army of nurses. Its income is counted in tens of thousands, its needs are counted in larger sums—and 170 years ago it had a shilling. To our mind this wonderful story can fairly be taken as a definite picture of the growth of medical science. The hospital, and there are, of course, others of which exactly an analogous story could be told, originates in the practical desire of a medical man to treat the sick poor. The movement is supported by the public, and as the beneficent results become manifest the work spreads and the support becomes larger. Then students are attracted, the school is founded, and the conjunction between medical education and hospital practice is established. And so the great general hospital becomes the expression of medical science in its highest, a blend of devoted service, of strenuous work, and of difficult learning.

We do not follow Mr. MORRIS'S book in detail. It has been, as he says in his preface, and as anyone who reads it can see, a labour of love with him to write it, and we commend it heartily both to the public and to the medical profession as not only a story of a great charity very well told, but also as a parable illustrating the growth of medicine in the course of 170 years. He devotes, however, a chapter to the future of voluntary hospitals, concerning which a word must be said. He discusses here a problem which is now much exercising the minds of medical men, and, indeed, of most of the thoughtful denizens of great cities, where poverty and sickness must necessarily abide in close proximity to wealth, to the machinery for the acquisition of wealth, and to the amenities for the distribution of wealth. All are asking themselves whether, in view of increasing expenses, the future of voluntary hospitals is secure. Mr. MORRIS'S view is that State aid will come to the rescue if voluntary subscriptions fall off, but his hope is that it may come without State control. He imagines a condition of things under which a voluntary hospital, brought by some inclusive scheme into line with Poor-law infirmaries, should receive from the State an addition of a percentage to its subscriptions or an annual grant depending upon the quality of its work, while the governors, chosen from among the supporters of the charity, should retain the full responsibility which they at present enjoy. We find it difficult to believe in any contribution from the rates towards the work of a hospital in return for which there would not be demanded some right of representation in the management of the charity. Not only do we find it difficult to believe in such a contribution being made, but we think that, if and when the public is taxed for the purposes of a hospital, it must have a voice in the control of the hospital. The whole subject, one of immense importance, is sure to come under public consideration when legislation ensues upon the Reports of the Poor-law Commission; and the advocates of the maintenance of the voluntary system must be awaiting, like ourselves, with keen interest the time when the political situation will permit of the introduction of such legislation. Whichever report is adopted ultimately as the basis of a new system of administration there is likely to follow, sooner or later, a development of institutional treatment paid for by the rates which must affect the position of voluntary hospitals in London and in the provincial towns where they exist. Such development may relieve the hospitals of patients who can more appropriately be treated elsewhere, and may assist such institutions in some instances by securing payment for patients for whom the rates should properly be responsible. It may thus leave a wider and truer field of usefulness open to the hospitals and yet may appear to narrow that field with the effect of diminishing the flow of subscriptions, since many persons finding themselves paying higher rates in order that there may be better institutional accommodation for the sick poor may become unwilling or unable to tax themselves voluntarily for a kindred purpose.

The State of the British Army.

FROM the annual report[1] on the British army recently issued by the War Office we learn that our Regular Army was on Oct. 1st last fully up to its established strength of 256,000 of all ranks; that the Army Reserve was practically up to its establishment of 137,000 men; but that the Special Reserve was still 20,000 short of the 90,000 required, and the Territorial Force still 43,000 below its establishment of 316,000. Of the Regular Army about 128,000 are serving at home, 78,000 in India, and 47,000 in the colonies. The majority of recruits during the last three years have enlisted for a seven-year period. In 1904 and 1905 nine years was the usual length of service, and in 1902 and 1903 three years; about 1500 men in each year are recruited for a long service period of 12 years; and in the year under review nearly 20,000 out of 37,000 enlisted for seven years. The transfers to reserve on completion of service, numbering 17,690, constitute the principal item of decrease in army strength; 2185 men were invalided, and 3573 were discharged after 12, 18, or 21 years' service. The total decrease, 35,124, is markedly less than in any of the years that have elapsed since the South African War. During the year under review the number of recruits enlisted was 3338 less than during the preceding 12 months.

Since the South African war we have heard a great deal about the difficulty in getting recruits of the right stamp, men physically sound and of good character and fair education. It has been hinted that the physical standard has in some cases been lowered in order that the numbers might be maintained; that the present-day soldier is, at any rate on joining the army, an ill-grown boy; and that many of these lads have to be discharged within a few months, as not likely to become efficient soldiers. There has been a considerable amount of truth in this, and yet the position of things during the past year, in which the number of recruits enlisted has been distinctly less than in any year since the war, is to be regarded as undoubtedly satisfactory, for the reason that the wastage has been diminished notably. The improvement has occurred all round; the losses by death, by invaliding, by purchase of discharge, and by desertion have all been less; so that although the recruits joined have been considerably fewer than in the previous year, the effective

[1] General Annual Report of British Army, including Report on Recruiting, for the Year ending Sept. 30th, 1909. War Office, 1910.

strength on Oct. 1st, 1909, was 241,422, as compared with 239,292 on the same date in 1908. On the whole it is considered that the improved conditions of service in the army are now being generally recognised, and that an increasing proportion of recruits realise that they are better off in the army than out of it. This state of things has had the further good effect of enabling the recruiting authorities to raise the physical standards on enlistment, and to pick and choose their material; for all infantry of the line the minimum height has been raised to 5 feet 4 inches, and we are told that this has not been the case previously since 1889. The percentage of rejections for want of physical development, 6·70, has been lower than in any year during the quinquennium except in 1908 (when it was 6·41), which seems to show that the physical condition of that part of the population that presents itself to the recruiting officer is, at any rate, not deteriorating at the present time. Moreover, the proportion of young soldiers invalided during their first two years of service has notably diminished: in 1904–05 it was 21 and 16 per 1000 for the first and second years of service respectively; it has come down to 12 in the first and 13 in the second year in 1908–09.

A very important section of the present report deals with the provision of employment for time-expired and reserve soldiers. The National Association for Employment of Reserve and Discharged Soldiers does a good work in bringing employers and would-be employees together, and in some instances county associations have voluntarily rendered help. Many Government departments, such as the War Office, Customs, Office of Works, and Post Office, also the police, and the great railway companies give employment to discharged soldiers of good character; it is gratifying to learn that in 1909 there were 20,906 ex-soldiers employed in the service of the different railway companies throughout the kingdom. This question is a most important one from the point of view of the well-being and health of the community. A certain number of ex-soldiers are undoubtedly ne'er-do-weels, but a large proportion are steady, respectable, well-educated, and disciplined men, fit for many positions of trust. A labour exchange for such men is needed; the present rather numerous agencies and societies somewhat overlap and interfere with each other. We should welcome a comprehensive scheme by which, for instance, the boy, leaving school at about 15, might pass through post-office or messenger work for three or four years; then enter the army for five or six years or more; then pass to the police, post-office, railway or other permanent employment. This applies to those who are not skilled workmen, belonging to the ordinary labouring class, that is nowadays fairly well educated, but, as this report says, "with little, or more often no knowledge of any skilled trade." The great majority of soldiers who are of this class, when they possess the asset of "good character" have admirable qualities within their own limitations, and are capable of rendering excellent service in return for employment which enables them to gain gradually the requisite technical knowledge. The promise of such employment on leaving the army should, moreover, stimulate many men to form good habits of living whilst they are still in the service.

Patients and their Friends.

A STRANGE disturbance of the peace was reported recently from Crewe. An outbreak of diphtheria has occurred in that town, and it became necessary to remove a number of children to the isolation hospital, to which their friends were denied admittance. Resenting exclusion, these ardent spirits are reported to have attempted to storm the walls of the building in their anxiety to visit their relatives, until, finally, police assistance had to be invoked to induce them to depart. The episode suggests a problem of practical medicine with which the practitioner is constantly being confronted, the decision as to whether a certain patient should be allowed to receive visits from his friends. In the case in point the custom which is almost universal in fever hospitals, and that rightly, appears to have been followed. We do not imagine for a moment that any parent was refused access to a dying child, for when once the last chance of life seems to skilled eyes to have been lost the law of common humanity overrides the law of common sanitation, which insists upon the isolation of a patient whose disease constitutes a source of danger to his neighbours. All intelligent people having to nurse a case of infectious sickness in a private house make arrangements by which not more than one or two persons shall come into contact with the patient, and the like self-denying ordinance, if so it can be called, is enforced upon the friends of infectious patients who are being cared for at the public cost.

But the problem of visitors to the sick covers a far wider ground than the risk of infection, for it is the effect which the friends will have upon the patient rather than that which the patient will exercise upon the friends that the practitioner has generally to take into consideration when he is confronted with the impatient request for admission to a sick-room. In hospital the matter is fairly simple. For obvious administrative reasons friends of patients are only admitted during certain visiting hours except when their names are upon the list of those dangerously ill or when a special grace for some particular reason has been granted. Although no one grudges the hours which the sick poor are thus enabled to spend at the bedside of their nearest and dearest at a time of real distress, yet all medical practitioners who have been hospital residents can probably recall instances where they would have given much for the authority to forbid absolutely the access of friends to some particular patient. Indeed, the sisters in charge of not a few children's wards, lovers of children though they were, have been known to declare that they would like to see a complete abolition of visiting hours, so far as their patients were concerned. This was not only on account of the risk of the introduction of infection, which is indeed almost in itself a sufficient cause to exclude visitors from children's wards, but because the hour following the departure of the parents is generally spent in loud lamentation by a number of infants, who, before the mothers' arrival, were in a state of blissful forgetfulness of their very existence. The exclusion of parents from the children's wards in ordinary circumstances may seem brutal, but we think it will be

supported by anyone who takes the trouble to analyse a series of hospital temperature charts of convalescent children and to note the number of unexplained rises on the evenings of visiting days. We believe, indeed, that some hospital boards of management have been bold enough to forbid the routine visiting of children's wards. On the other hand, we imagine that in certain instances the visit may have an excellent educative influence upon the parents themselves, who have the opportunity of seeing what cherubic little people their own children appear when properly clean and tidy, in contrast to the dirty, uncared-for condition into which too many of them are allowed to drift at home. But there are other hospital visitors besides those to the children's wards whom it would be desirable oftentimes to prevent from visiting their sick friends. We have in mind those who, upon receiving the report of the serious illness of a relative in hospital with the consequent permission to visit him at all hours, hasten to his bedside attired in the funereal "blacks" which do duty upon all solemn occasions, and sit through the night assuring him at intervals that his sufferings will soon be over. Of course, if the patient be really destined for eternity it would be meddlesome to seek to deprive him of the consolations customary to his condition and station, but in those not infrequent cases where a chance of life remains we are assured that the suggestive influence of the mourners-apparent may determine the chances against the sick man, and we should applaud the action of a medical officer or nurse who banished the croakers from the ward. True, it is a difficult and delicate matter to judge when such an exercise of authority would be justifiable, but the practice of medicine largely consists in the formation of difficult and delicate judgments, humane no less than scientific.

In hospital practice, however, in this as in other matters, it is generally possible to take the best course for the patient, as the staff and governors are in great measure the masters of the house and dictate the situation. But in the private practice of medicine the position is reversed, and although a majority of people asking a physician's advice concerning the desirability of disturbing his patient will abide sensibly and loyally by his decision, yet most family practitioners have met the cantankerous person who refuses to be browbeaten, and insists upon going to cheer up the invalids when they themselves, perhaps, have actually requested the medical attendant to save them from the visitations of such impetuous friends. On the other hand, it must happen sometimes that although medical prudence would desire the patient to be left alone with a single skilled attendant, the enforced absence of some dear friend or relative may cause such fretfulness and mental distress that it is better to sanction admission to the sick room and stand the chance of the patient becoming unduly "excited" as a consequence. Indeed, the constant presence of wife or husband as a supernumerary nurse during a severe illness, whether it be at home or hospital, may not only help to give comfort and confidence, but their cheerfulness and encouragement may have as powerful a suggestive effect in helping the sufferer through his illness as the croaker may have in the opposite direction. Probably not a few of our readers could tell tales of devoted attendance through many days and nights of a seemingly desperate illness by friends who resolutely refused to let their dear one die. The physician could want no better adjuvant to his ministrations than such a presence at the bedside, and it does not require a profound knowledge of human nature to judge whether a patient is deriving good or harm from the personalities of those who are about him. When the practitioner finds that one is doing harm we conceive it to be his duty to speak straight out to the unwitting offender, as tactfully as he may for his own sake, but none the less plainly. "Friends should associate friends in grief and woe," it is true, but not when one lies sick unto death and the other is a prophet of evil, or a prater, or a bore.

Annotations.

"Ne quid nimis."

ARMY MEDICAL UNREST.

FOR some time back there has been a feeling of uneasiness and uncertainty amongst the officers of the Royal Army Medical Corps as to their future prospects by the adoption of the system of promotion by selection. It is not our present purpose to criticise or even inquire into the ways and means by which selections to the higher ranks are determined as long as due weight is accorded to seniority in the Army List, and as long as capable men of good record and with nothing against them are not superseded by a junior for whose superior capability there is no evidence. Such supersession when carried out, while rewarding the officer promoted, is a grave injustice, pecuniary and otherwise, to those whom he supersedes, as they will probably lose all prospect of further advancement, having to retire either on account of age or a fixed time limit of tenure of their appointments. The Royal Warrant may be termed the Magna Carta of the Royal Army Medical Corps, as it lays down the rules and regulations affecting the pay, prospects, and promotion of its officers, and may thus be considered the basis of agreement between the civil practitioner when he joins the medical department of the Army and his Sovereign who actually signs his commission. In a corps of nearly 1200 officers the prospects of reaching the highest ranks are small, but to allow of the chances being fair and more evenly distributed the Royal Warrant distinctly lays down that the surgeon-generals must retire on reaching the age of 60. This provision has been observed until the recent appointment of the Director-General of the Army Medical Service. Surgeon-General W. L. Gubbins, M.V.O., has been retained on the Active List, notwithstanding he was 60 years of age last July, thus contravening the Royal Warrant and stopping promotion. We do not mean to imply that this officer is not a capable one or that his choice is not amply justified by his record. We have every reason to believe that he will discharge his duties in an admirable manner. But there is no getting out of the fact that the authorities have not acted up to the spirit of their regulations. The consequences of this promotion will have far-reaching effects. The very fact of making such a promotion signifies that the other eight surgeon-generals may not obtain further advancement, while it supersedes one surgeon-general of exceptional claims. The personal argument, however, we do not propose to use. What is important is that if merit and distinguished service are not rewarded in the

highest ranks the prospects of the juniors in the service cannot but suffer. The Royal Army Medical Corps is in an exceedingly strong position now, a position at which those who recall the times not far gone by must almost wonder. Surely it is unwise to endanger the chances of recruiting officers from the best material. But this is what may happen if young men are told that they cannot rely upon the Royal Warrant under which they agree to serve.

THE FREE FEEDING OF LONDON SCHOOL CHILDREN.

A REPORT came before the newly elected London County Council at its first meeting with regard to the administration of the Act under which meals are provided for necessitous school children. It may be remembered that in December last the Finance Committee of the late Council noted with some alarm a large increase in the number of meals supplied, and referred in strong terms to an item of £26 as the total sum likely to be recovered in one year from parents against an expenditure upon free meals of nearly £70,000. The Finance Committee thought the Education Committee in its circulars to parents did not lay sufficient stress on the obligation of the local authority to obtain reimbursement if possible, and expressed the opinion that "recovery of cost should be the rule, not the exception."[1] The Education Committee now agreed to strengthen the wording of the circular letters, and also to modify in some of its details the procedure by which children are put upon the feeding lists, but in regard to the main criticisms of its policy the Education Committee said the guardians of the Council's purse laboured under a complete misapprehension. The estimate of the amount to be recovered from parents was necessarily small because the Council had availed itself only to a very limited extent of the power to provide meals for non-necessitous children whose parents were willing to repay the cost. The great majority of the children fed were really necessitous, and therefore the recovery of anything more than a small amount could hardly be hoped for. Without exception members of the care committees had expressed the opinion that only in rare instances was there any possibility of obtaining repayment, and even in those cases it would be difficult to prove sufficiency of means to the satisfaction of a magistrate. Although the number of meals provided showed a large increase (from 4,546,000 in the last financial year to 7,702,000 in this) the number of children fed had only risen by 2000. The reason for the disparity of the figures was that meals had been given during the summer as well as in the winter, and more meals had been given per head. Since Christmas the number of children fed weekly has been about 52,000.

A STANDARD MOTOR WARNING.

IT seems desirable in the matter of methods of warning in our thoroughfares that some uniform system should be adopted by motor vehicles. As things stand, there is nothing apparently to prevent the most fantastic methods of alarm being adopted, and the result may be irritating if not occasionally disastrous to the public. In some instances the alarms are unnecessarily exaggerated and weird, and when a more or less foreign noise is suddenly released the effect may well give a shock to nervous persons. At first it seemed to be a tacit understanding that the single reed horn was to be identified with the motor, but the success of this led cyclists to adopt the same means of alarm so as to ensure (on false pretences) a clear road. Next a pair or even three reeds were adopted, yielding a more or less harmonious combination, then came the shrieking syren, and again, a contrivance which sounded progressively up and down the principal notes of a major chord. Some retain the old bell introduced many years ago by the cyclist, and one curious device produces a not unpleasing noise resembling a loud chuckle. Now all this is confusion and Babel and a source of real irritation, and surely there should not be any question of confusion arising in connexion with signals given to warn the public of danger. Is it unreasonable to suggest, therefore, that there should be some official control exercised over the means adopted in motor traffic for sounding a warning note, and that a standard method should be insisted upon? Let it be a bell, a horn, a syren, a whistle, or what we will, but let only one uniform distinctive kind, instead of all sorts and conditions, of alarm be permitted for motor vehicles. There is nothing impracticable further in the suggestion that bicycles should be restricted to a distinctive alarm also. It is a common experience now that some cyclists delight to sound a motor horn and frighten people unnecessarily. Such a silly nuisance should be suppressed.

PRACTICAL STERILISATION BY MEANS OF ULTRA-VIOLET RAYS.

THE germicidal action of the ultra-violet rays has been referred to more than once in these columns, and there seems to be little doubt that this action will shortly be made available for the purposes of practical sterilisation. In what exact way the ultra-violet rays act is not certain, but one view is that they produce ozone. Whatever the nature of the action may be, it seems clear that their application for the purpose of sterilising articles intended for human consumption will eliminate the objection to the use of chemical antiseptics, the effect of which upon the human organism may be harmful. In an interesting paper which has reached us on the Sterilisation of Water by Means of Quartz Lamps, by Dr. Max von Recklinghausen, it is stated that work on a very large scale has lately been done in France on this subject, and has developed the entire system of sterilisation of different liquids used for alimentary purposes, based on the effect of the ultra-violet rays created in Cooper Hewitt lamps made from transparent quartz. The chief work in this line has been done by Professor Henri in the Physiological Laboratory of the Sorbonne together with Dr. André Helbronner, who coöperated with Dr. Max von Recklinghausen with a view to developing an entire sterilising system of the type described. The preliminary work was done by studying the action of the ultra-violet rays on different types of microbes and the influence of the different wave lengths. Dr. Roux of the Institut Pasteur, where a good many of the experiments were made, presented to the Académie des Sciences some of the work done by the above cited gentlemen. Technically speaking, the results so far have been the development of a small water steriliser for hospital use whereby 132 gallons of sterile water are produced per hour from ordinary city water by means of one Cooper Hewitt lamp, type "Silica," absorbing three ampères at 110 volts. Within a short time a very large sterilising outfit, based on somewhat similar ideas, will be running, which will sterilise 3500 cubic feet of water per hour, this being large enough to treat the entire water-supply of a town of about 10,000 inhabitants. The installation of the lamp, it is stated, is a matter of no difficulty, all that is necessary being to connect up to the terminals provided in the dome top of the apparatus and to make the adjustment necessary for the voltage of the particular circuit. In order that the supply of water delivered from the apparatus may be absolutely sterile, or sterile to

[1] THE LANCET, Dec. 18th, 1909, p 1843.

any required degree, it is necessary that there should be means of dealing with the various water pressures met with in different districts. To accomplish this purpose the inlet pipe is fitted with an adjustable valve of special pattern which can be readily set, so that when full open the delivery from the apparatus does not exceed the quantity specified, this, in the case of requirements being for absolutely sterile water, being 132 gallons per hour. The water enters the chamber formed by the outer cone with a swirling motion. At the top of this cone it overflows and finds an outlet at the bottom of the inner cone, up which it rises and flows out at the discharge pipe. The swirling motion is maintained during the complete passage of the water through the apparatus, in order that it may be thoroughly stirred up and all microbes presented to the action of the light, the water coming under its influence on two distinct occasions. Draining cocks are provided on the apparatus to enable it to be thoroughly emptied should circumstances arise whereby it would not be used for a considerable time. Not only does this system provide, in the case of the apparatus under discussion, a continuous supply of sterile water available within five minutes, but the water or any other liquid that may be treated is unaffected as far as taste is concerned, as it retains all natural gases and salts in solution. The work of Professor Henri, Dr. Helbronner, and Dr. Recklinghausen has also been directed towards the complete sterilisation of milk, and this they have also accomplished. The apparatus for this purpose is more difficult to build than that for the treatment of water. Water is very transparent to ultra-violet rays; milk, however, is practically opaque to these rays, and special precautions have to be taken so as to bring it thoroughly under their influence.

THE EMPLOYMENT OF ARTIFICIAL RESPIRATION BY THE METROPOLITAN POLICE.

WE have received from Mr. Clinton Dent, chief surgeon of the Metropolitan Police, a statement and summary of all cases dealt with by the police in which artificial respiration was performed between Jan. 29th 1909 and the same date in 1910. Mr. Dent writes that artificial respiration was employed in 43 cases and on 48 persons. In 47 of these it was actually employed by the police, and in one by a private person. In some of the cases it was performed in part by the divisional surgeon. The Schäfer method alone was used in 34 cases; 25 of these were cases of immersion; 18 were successful and 7 unsuccessful. Judging by the reports, it is quite possible in some of these successful cases that the patient might have recovered without any artificial respiration at all, but this does not imply that the method was unnecessarily employed. In a case of a woman who had swallowed some paraffin and then thrown herself into the water, the application of the Schäfer method on the bankside restored natural breathing, but the woman died shortly after in hospital from the effects of the paraffin poisoning. The case may fairly be classed as a successful one as regards the Schäfer method. In some of the unsuccessful cases immersion had been prolonged and recovery was out of the question. In the case of a man, aged 64 years, who had only been immersed for a short time, the day was very cold, and death was ascribed by the divisional surgeon to heart failure. The Schäfer method was employed in 9 cases other than immersion. Two of these were cases of poisoning by chlorodyne and opium respectively, one of heat-stroke, one of coal-gas poisoning, and 2 were cases of suffocation by fumes in a burning house; 2 were attempted suicides by strangulation, and in one a boy was pinned by a cart shaft across the throat. In 6 of these recovery took place. Of the 3 unsuccessful cases one was a case of coal-gas poisoning in a woman who had probably been dead for some hours. In the other two death was the result of chlorodyne poisoning and of opium poisoning. The Schäfer method was employed on 13 occasions in children of 10 years old and under. In one case the children (who were very gallantly rescued from a burning house) were aged respectively 3 years and 1 year and 10 months. This shows conclusively that the view which has been held that the Schäfer method is unsuitable in the case of young children is erroneous. The Silvester method was used successfully in 3 out of 7 cases of immersion. In one of the unsuccessful cases a woman had drowned her three young children in a bath. The Silvester method was employed by direction of the divisional surgeon, but recovery in this instance was impossible. In a case of attempted suicide by strangulation the Silvester method was employed successfully by a police constable "as he was most experienced in the use of that method." In three cases of immersion, involving four persons, both methods were used. Mr. Dent observes that the number of cases is far too small to furnish any basis for comparison between the two methods, but to his mind the year's experience shows conclusively that the Schäfer method is thoroughly efficacious, and that even in the hands of persons who have had no long experience it can be easily applied. It has also been proved to be an effective method in cases of many kinds for which artificial respiration is demanded.

ANTIMONY COMPOUNDS IN THE TREATMENT OF TRYPANOSOMIASIS.

THERE can be no doubt that arsenic in the form of atoxyl has proved of value in the treatment of human trypanosomiasis when given at a sufficiently early stage of the disease. Unfortunately experience has shown that trypanosomes can develop a tolerance of this remedy, and hence it has become necessary to find, if possible, some other drug of equal value which may be used as a substitute or administered in combination with atoxyl. The near chemical and pharmacological relations of arsenic and antimony had suggested the use of the latter, but the irritant action of the ordinary antimony salts appeared to forbid their use by hypodermic injection. Attempts have already been made to form organic compounds of antimony analogous to atoxyl, and not long ago Professor A. R. Cushny submitted to Plimmer and Thomson for experimental trial a compound of glycine and antimony. As this compound, however, proved difficult to make and was unstable these investigators substituted for it tartar emetic. The results proving satisfactory, Dr. John D. Thomson and Professor Cushny planned and carried out a series of investigations with a view of determining the limits of usefulness of other antimony compounds. The experiments were carried out at the Lister Institute of Preventive Medicine with rats infected by a strain of nagana (T. brucei), and the results of this research were embodied in a paper, which was read on Jan. 20th before the Royal Society, on the Action of Antimony Compounds in Trypanosomiasis in Rats, being a report to a subcommittee of the Tropical Diseases Committee of the Royal Society. After the investigators had tested compounds in which antimony is more firmly combined than the ordinary salts, and after a trial had been made with a glyceride of antimony and with sodium sulphantimoniate (Schliffe's salt), all of which, however, presented objections of one or another kind, a large number of experiments were done with combinations of antimony with the organic acids corresponding to the ordinary tartar emetic. Among the salts examined were the lactate, citrate, malate, and mucate. The mucate was investigated with the idea that its multiple

hydroxyl groups might prove to have special powers of retaining antimony in solution, but it was found that while powerfully trypanocidal it induced great local irritation, which was a barrier to its employment. The citrate seemed inferior to the malates and tartrates, among which the sodium and potassium salts were equally efficient trypanocides, but the substitution of an alkyl radical for the potassium or sodium salt seemed to be attended with advantage. Solutions of ethylantimonyl tartrate were prepared by Professor Collie, and this proved a very efficient trypanocide, causing no local irritation in the rat. After injection of 1 cubic centimetre of a 0·2 per cent. solution into rats of 100 to 200 grammes in weight, trypanosomes, though previously present, disappeared entirely from the peripheral blood within one or two hours. Dr. Thomson and Professor Cushny assert that in their experiments no other drug has given such favourable results, but it will be necessary to test it against other species and strains and in different hosts before any general statement can be made as to its usefulness. Finally, some infected rats were treated with a solution of ethylantimonyl tartrate and atoxyl, which are stated to be respectively the best antimonial and arsenical trypanocides known to us at present. But the results of the combined medication were scarcely superior to those of the ethylantimonyl tartrate alone. It is, however, suggested by the investigators that by a more accurate adjustment of the two drugs the advantages of diminished recurrence of the trypanosomes and low toxicity to the host might possibly be combined. From their own work and that of others the two observers think that sufficient data have been obtained to indicate some points which must be taken into consideration in attempting further advance in the treatment of trypanosomiasis. These are: (1) As regards the compound it must be non-irritant and capable of remaining in perfect solution at the temperature and alkalinity of the tissues; (2) it must act quickly on the trypanosomes, for otherwise these parasites seem to acquire a tolerance to it; and (3) when the trypanosomes have been expelled from the blood by a single full therapeutic dose, there must be no recurrence in the majority of cases within some fixed time which will vary with the particular host and the species and strain of trypanosome in use. The longer the time during which there is no recurrence in the majority of animals treated the more promising is the outlook for the drug under trial.

BEQUESTS TO HOSPITALS.

IN spite of the fact that nearly every hospital, in making its appeal to the charity of testators, suggests a convenient form of clause for insertion in the will, litigation is not an infrequent result of this class of eleemosynary bequest. There may be some doubt as to the institution which it is desired to benefit, or the gift may be coupled with some fanciful restrictions which prevent the hospital governors or other administrators of the charity taking full advantage of it. But the difficulties attending a bequest to a specific institution are small as compared with those which attend the interpretation of a will by which a munificent testator desires to start an entirely new foundation. As a legal document the will may be perfect of its kind; but it may contain the rudiments of a scheme which cannot, without the aid of the court, be worked out in practice. The court must be asked to apply the doctrine of *cy-près*, which (as an old lawyer once wrote) "is a curious and excellent sort of learning." It means that where the intentions of a testator are avowedly charitable but are incapable of being exactly carried out for one reason or another the funds will be applied to some other charitable purpose similar to that which the testator desired to foster. A notable example of an application of the doctrine of *cy-près* came before Mr. Justice Eve recently. A Mr. Benjamin Weir left a sum of £100,000 to found a hospital for the benefit of Streatham and neighbourhood. He also left two freehold houses, one of which was to be used as a hospital. By the terms of the will the trustees were entitled to apply the money, &c., to a hospital "or other medical charity." Finding that the house left in this way was too small to be made into a hospital, the trustees obtained the sanction of the Charity Commissioners to a scheme by which one of the houses is to be turned into a nursing home and the other into a dispensary, while a considerable part of the bequest is to be handed over to the Bolingbroke Hospital, which is in future to be called the Weir and Bolingbroke Hospital. A dissentient trustee having objected to this scheme as being foreign to the objects of the testator, application had to be made to the court. It has now been sanctioned owing to the application of the doctrine of *cy-près*. An interesting example of an older application of this doctrine may be mentioned. In 1643 a testatrix gave a sum of £200 to be laid out in the purchase of lands of the annual value of £10. Of this one-half was to be devoted to the relief of the most poor and needy people of good life and conversation in the parish of Kensington, and the other half to apprentice a poor boy. This charity eventually became what is now known as the "Campden Charity," which had an income of £2000 a year in 1880, and doubtless has more at the present time. The court in that year sanctioned a scheme by which the funds could be applied to, *inter alia*, subscriptions to dispensaries and hospitals in the parish.

THE ACCUMULATION OF COAL GAS IN DISUSED SEWERS.

IN the annual return for 1909 made by Dr. F. J. Waldo, coroner for the City of London and for the borough of Southwark, is an interesting record of the causes and circumstances of the explosion of coal gas in last December in a disused sewer in Bermondsey, which was followed by a fire and accompanied by loss of life. The findings of the jury, in answer to the coroner, place it upon record that the explosion or series of explosions which caused the death which formed the subject of the inquest were due to the ignition of a mixture of coal gas and air which had collected in a disused sewer running under Grange-road, Bermondsey. The actual ignition took place through the use of a lighted tarred rope by men employed by the South Metropolitan Gas Company who, however, were absolved by the jury from any charge of criminal negligence in this respect. A cross-pipe or rider connected two gas mains at the point where the gas, which afterwards accumulated in the sewer, escaped, and this rider was fractured owing to an escape of water from a 4-inch "spur" attached to a water main. This "spur" was broken owing to its being partly fixed or included in some brickwork in connexion with the construction of a new sewer, an act for which the responsible owners of the sewer, the London County Council, were held by the jury to be responsible. With regard to the negligence, or want of reasonable precautions, which led up to the accident through which the deceased came to his death, the jury divided the blame between the London County Council, the Metropolitan Water Board, and the South Metropolitan Gas Company, and an important sequel to the inquest consisted in a letter addressed to the President of the Local Government Board by Dr. Waldo, and set out at full length in his report. This letter called attention to the inquest, gave extracts from the evidence, and suggested the desirability of an inquiry to be held by the Local Government Board with the coöperation of the City Corporation, the London County Council, and the metropolitan

borough councils, into the condition of disused sewers, and the means for preventing such explosions in the future. No such inquiry has been held, the consent of the various councils having no doubt not been easy to obtain. It is unfortunate that in the absence of such inquiry there should be no public knowledge of the extent to which disused sewers may exist, as the inquest referred to has shown how easily they may become a source of serious danger to the public, and the absence of any definite individual responsibility with regard to them.

FINGER-PRINT IDENTIFICATION.

WE are informed that there is a movement on foot to recognise in some way Mr. Henry Faulds's work in introducing the method of identification of finger-prints to public notice. To Mr. Faulds, a member of the medical profession and for many years a surgeon in Japan, belongs the honour of first publishing a proposal to use dactylography for identification, and there is no doubt that his work was greatly instrumental in securing in England the official use of finger-prints for the identification of criminals. The work of Sir W. J. Herschel, Sir Francis Galton, and Sir James Henry in the same field is well known, but a contribution by Mr. Faulds, which was published in *Nature* in 1880, was the first information given to the public on the subject. We shall be glad to record that our medical *confrère's* ingenious and valuable labours have received some public recognition.

PLAGUE PREVENTION IN GERMAN EAST AFRICA.

AN official report[1] has been published of the steps taken to protect German East Africa against plague when it broke out in Zanzibar in 1905. It appears that these steps were based on the three principles—examination of ships, control of rats, and early recognition of cases. Examination of ships must be carried out very tactfully or the trade of the port may be ruined, for the trade is mostly done in dhows—small sailing ships with native crews. They are of light draught and lie often on the foreshore, so they are high and dry at low water, allowing the rats, like their other passengers, to walk ashore. To keep these craft always anchored in deep water, or to disinfect them all, or even to examine their cargoes, would cost the owners money, destroy their small profits, and drive them away from the port. Consequently only those ships were dealt with which had suspicious cases in men or rats, or which had come from ports declared infected. A Clayton disinfecting apparatus was provided at Dar-es-Salam, the capital; quarantine stations were established here and at Tanga, and these places, with Kilwa and Lindi, all appointed port medical officers and obtained a disinfecting plant. Rats were kept down by native rat-catchers, poison, and bounties, also by cats, and indirectly by improved conservancy. Early diagnosis of the disease is said to be the readiest manner of controlling the disease. News of outbreaks is now very quickly circulated from port to port. Skilled bacteriologists are appointed to Dar-es-Salam and other stations, three moveable plague laboratories are sent where required, and at Dar-es-Salam in 1905 a plague institute was built where research is carried out and Haffkine's plague vaccine is prepared. At all places doubtful deaths and suspicious illnesses are investigated microscopically, while these investigations are, at Dar-es-Salam, extended and controlled by inoculation experiments. Rats caught at Dar-es-Salam are all examined. Out of 1344 which came under observation to Sept. 30th, 1908, 5 only had bacilli showing polar staining, and of these none were pathogenic to guinea-pigs. At the end of September, 1908, a native boy, who had done no work in the harbour or on ships, came into hospital complaining of fever. Several blood films were examined in the next two days for malaria and relapsing fever spirilla, but without result. On Oct. 1st a hard bubo formed in the right groin; this was excised on the 3rd, the pyrexia ceased on the 9th, the wound healed in three weeks, and he was discharged from hospital on Nov. 13th. On section the bubo was found to be dull red, with no foci of suppuration. In its juice were bacilli capable of polar staining. Two guinea-pigs were inoculated subcutaneously with this juice. One died in ten days, the other was then killed, and in each were found considerable thickening of the skin about the seat of inoculation, enlargement of the liver and spleen, whitish patches in the spleen and lungs, and numerous Gram-negative bacilli showing polar staining were found in all the organs. As the infection was passed on through guinea-pigs its virulence became exalted. On agar there developed dewdrop-like colonies of non-motile, Gram-negative bacilli, becoming grey and taking a polar staining, and agglutinated by Pasteur plague serum in 1–800 dilution. This investigation proved that the bubo had been caused by an attack of plague, and it is noteworthy that without help from experiments on living animals this commencing epidemic could hardly have been recognised. During the next three months 12 cases in all were considered, of which 3 remained suspicious, whilst 9 were proved to be cases of plague. After September the disease began to appear in rats, and from October to February 107 were found infected out of 4030 examined. The plague-carrying rats were nearly all found in that district of the city where three-quarters of the plague cases occurred, but only two rats came from the houses of the people infected. Still, great attention was paid to rat destruction, and a party of two medical men, four sanitary inspectors, and from 10 to 20 negroes were employed in their destruction by traps and poison (phosphorus paste). The water drainage channels were disinfected by the Clayton apparatus every two months, and extra attention was paid to the removal of rubbish which might harbour rats. To prevent damage to other ports or countries, information was immediately sent out, emigrants were inspected, and their baggage fumigated. The original paper is a luminous account, illustrated with plans and tables, of a well-devised plan energetically followed, and crowned with the success it merited. It is noticeable that clinical observation is not relied on for the detection of the disease, and that mild cases of bubo may be the only proof of the existence of an epidemic. Of 7 cases seen in life only 1 died.

[1] Archiv für Schiffs- und Tropen-Hygiene, January, 1910.

TWO UNUSUAL CASES OF CHRONIC RETENTION OF URINE.

IN a paper read before the Berlin Medical Society, and published in the *Berliner Klinische Wochenschrift* of March 7th, Professor L. Casper of Berlin described two interesting and unusual cases of chronic retention of urine. The first patient was a man, aged 68 years, who was seen by Professor Casper eight years ago with retention; since this time he had not been able to pass urine except by catheter. Examination showed that no mechanical obstruction was present and that the prostate was small rather than large. There was no indication of cerebral disease or of tabes. There was no history of syphilis, and no other symptom of disease, the patient being able to attend to his business. Professor Casper therefore regards the case as one of "senile bladder" (*Altersblase*), developing relatively sooner than usual, the pathological basis of the affection being a degeneration of the bladder muscle associated with a connective tissue sclerosis, like that described by Guyon and Lannois in 1885. The second case was more obscure, and the manner in which Professor Casper arrived at his diagnosis is both interesting

and instructive. The patient was a man, aged 34 years, who for the past six years had not been able to empty his bladder except by catheter. As in the previous case, there was no evidence of mechanical obstruction, of nerve disease, or of syphilis. The age of the patient excluded the diagnosis of senile bladder, and the actual nature of the case remained obscure until Professor Casper showed the patient to his colleague Dr. Th. Mayer on account of a peculiar condition of the skin over both knees and hands. This was recognised as an atrophic condition of the skin, and was found to be associated with some atrophy of the interossei and lumbricales of both hands. These atrophic processes led Professor Casper to attribute the inefficiency of the bladder to a similar condition of its musculature, and cystoscopic examination lent support to this view, since a number of diverticula were found to be present. Apart from congenital diverticula, such appearances are only found in cases where the pressure of the urine causes the bladder wall to yield, and their occurrence in a young man without mechanical obstruction of the urinary passages led to the conclusion that the bladder wall was partly atrophic and had therefore yielded to the ordinary pressure. The case was therefore regarded as a tropho-neurotic affection with atrophy of various structures. This diagnosis excluded the use of operative measures for treatment, which therefore consisted simply of catheterism. It will be interesting to see if Professor Casper's communication serves to bring forward records of similar cases.

DIFFICULT POINTS IN LIFE INSURANCE.

One of the most frequent obstacles to the passing of lives for insurance is the presence in the urine at the time of the examination of albumin or of sugar or some other substance which reduces Fehling's solution. All medical examiners must be familiar with the type of case in which everything appears satisfactory—family and personal history, physique, and physical examination—until the urine is tested and this is found to contain one of these substances. The presence of albumin or sugar on one occasion may be purely an accident, but it is only possible to judge of this after examinations of other specimens of urine. It is the usual practice of medical examiners for insurance at a little interval to examine other specimens of the urine passed either in their presence or in that of some agent of the insurance company. If these specimens prove to be normal the life may usually be accepted at ordinary rates, but if they be abnormal there is no alternative but to postpone acceptance or to decline the life. Sometimes an immediate acceptance is desired without waiting for further tests and then an extra rating may meet the case, and this rating may be removed if it is found later that the albumin or sugar was purely temporary. This matter has been brought to our attention by a medical correspondent who considers, and, we think, with some ground, that he has a grievance against an insurance company and its medical officer. The facts appear to be as follows. A medical practitioner of over 20 years' standing wished to insure his life for £500 and was examined by the medical officer of a first-class company. For several weeks he heard no more about the matter, and then on inquiry of the agent he was told that the medical officer had advised that the proposal should lie over for three months. He subsequently ascertained that the medical officer reported that the urine had a trace of albumin and phosphates and a specific gravity of 1012. Examinations of the urine by the candidate for insurance before the medical officer's examination had failed to reveal any abnormality, and the same healthy result was obtained afterwards. The candidate for insurance then submitted himself for examination by a leading practitioner in the town where he resides, and was reported to be sound in every way, the urine being quite normal. As far as we can judge from the facts put before us, our correspondent seems to have been treated somewhat severely in having his case postponed for three months on the ground of one examination of the urine showing a trace of albumin. But we see no reason to think, as our correspondent does, that the medical examiner made any mistake in testing the urine. There is no reason why albumin should not be present with a specific gravity of 1012. Indeed, it is usually with urine of low specific gravity that traces of albumin are found. Moreover, the fact that albumin has not been found before or since does not make it less possible that a trace of albumin was present at the examination for life assurance. The applicant meanwhile has withdrawn his proposal, but we have no doubt that if he wished to proceed with it he would now find no difficulty in getting acceptance at the same or another office. We suggest that he apply to the same office again.

POOR-LAW MEDICAL RELIEF.

A CIRCULAR has been issued recently by the Local Government Board to boards of guardians concerning the administration of out-door relief to the poor. The short section concerning medical relief is couched in general terms, but should encourage guardians to take a more generous view of their responsibilities in this matter than has always been the case hitherto. The recommendation reads as follows: "In the administration of out-door medical relief the same care should be observed by the guardians as in the case of ordinary out-door relief. While there should be precautions to prevent an undue resort to medical relief at the cost of the rates, it is important that every facility should be provided to enable the sick poor to obtain the medical assistance of which they stand in need. For this purpose the medical relief districts should be so arranged that the services of the district medical officer may be readily available, and steps should be taken to ensure that there is no unnecessary delay in obtaining a medical order. It is especially important that the guardians should be able to supply the services of nurses in case of need. Nurses are generally best provided through the agency of local nursing associations, and the Board are willing, as in the past, to sanction subscriptions by the guardians for this purpose. In a recent circular letter the Board made a similar suggestion as regards midwives. The Board recognise that much good is done by means of provident dispensaries and medical clubs, and they consider it desirable that the guardians should avoid action which may have the result of discouraging membership of such societies."

THE VARIETIES OF TUBERCULIN.

IN THE LANCET of March 26th, p. 844, we published a lecture by Dr. Nathan Raw on the Treatment of the Surgical Forms of Tuberculosis by Tuberculin. In it the writer drew attention to some of the various forms of tuberculin now employed. We have received a pamphlet containing the report of a discussion which took place at the German Pharmaceutical Society in February of last year. The discussion was introduced by Professor W. G. Ruppel with a paper entitled "Tuberculin and other Specific Preparations as an Aid to the Diagnosis and Treatment of Tuberculosis." Professor Ruppel related the history of tuberculin from the time of its introduction by Professor R. Koch in 1891. He then gave a brief account of the method of manufacture of the substance and the modifications which were subsequently introduced. He showed that the failures met with in the earlier days of its use were due to the large doses employed. Now that it has been demonstrated that an immunising response can be evoked by minute doses numerous observers have again employed the remedy both in medical and surgical cases. Professor Ruppel's remarks will

well repay perusal. In his description of the various forms of tuberculin and the allied preparations he naturally referred mainly to German firms; nevertheless, most of these preparations can now be obtained in this country. His descriptions were rendered more interesting inasmuch as a brief account of their methods of manufacture was given. In discussing "Koch's old tuberculin" he referred to the ophthalmic and cutaneous reactions which have been widely used for the purposes of diagnosis and to which we have frequently referred in our columns. Professor Ruppel spoke favourably of the results obtained by "Koch's new tuberculin—T.R." He also mentioned a preparation known as tuberkulol, with which Professor Landmann claimed to have obtained satisfactory results. Attention was also drawn to certain other preparations, such as tuberkulonastin and the "tuberculine de Béraneck," which are less known in this country.

Looking Back.

FROM

THE LANCET, *SATURDAY*, March 31st, 1832.

OBSERVATIONS ON

THE INFLUENCE OF FEAR

IN PREDISPOSING TO DISEASE.

By JAMES CLARKE, *Esq.*, *Assist. Surg.*, *R.N.*

THE human body, it is evident from repeated observation, possesses at different periods of life, greater or less powers of resistance within itself, to the operation of those diseases excited by means of atmospheric influence.

In whatever mode a vitiated atmosphere has the effect of lighting up disease in the body, of this we are certain, that a continued and modified exposure to its influence, deadens its power, and in a peculiar manner having impregnated the constitution, renders it free from attack.

A robust state of health is by no means necessary to a person undergoing this trial; although, at the same time, absolute debility is to be avoided. How often do we see nurses, who in general do not enjoy good health, engaged, daily, attending the most fatal cases of typhus, small-pox, and other acknowledged contagions, while a casual visitor in rude health falls a victim to the pest! Often does it happen that a delicate female may attend on a relative during the whole range of a fatal case of typhus without experiencing any bodily illness, but the moment the object of her hope has died, her mind sinks within her, and the deadly poison works upon her harassed frame.

In the operation of miasmata on the system, a great deal I conceive must be taken into consideration, with respect to mind and body. In the case of a nurse or physician having a comparative immunity from contagion, it is evident, as regards the operation of all poisons on the body, aerial or otherwise, that habitude to them materially weakens their force. Let us add, that from constant intercourse with the sick, their minds are perfectly free from alarm, and no useless fears prey on their nervous system. In accordance with this rule, an infant will be found uninjured sucking the breast of a mother dying of plague. When a stranger, perhaps in rude health, visits a patient from choice or necessity, labouring under a contagious fever, from the want of habitude to scenes of this description, he naturally feels an awe, if not actual fear, come over him. This of course must render his body more susceptible to the influence of the morbific cause, and it is no wonder if he imbibes the contagious miasm.

Again, on the other hand, we have seen the wonderful influence of hope in preserving the body secure during the intercourse with the sick, and the consequent infection on its being lost. There can be little doubt that during the panic of an epidemic disease, a great many are rendered susceptible by the influence of fear and other depressing passions. This is more particularly the case on board of ships, where the healthy and sick are necessarily nearly approximated.

SECOND REPORT OF THE DEPARTMENTAL COMMITTEE APPOINTED TO INQUIRE INTO THE LAW RELATING TO CORONERS AND CORONERS' INQUESTS, AND INTO THE PRACTICE IN CORONERS' COURTS.[1]

THE second report of the Departmental Committee on the Law relating to Coroners was issued last week as a Parliamentary paper. It will be remembered that Mr. Herbert Gladstone, Home Secretary, in December, 1908, appointed the committee with the following constitution: Sir Mackenzie Dalzell Chalmers, K.C.B., C.S.I. (chairman), Sir Malcolm Morris, K.C.V.O., Sir Horatio Shephard, Mr. T. A. Bramsdon, M.P. (now Sir Thomas Bramsdon), and Dr. William H. Willcox. Mr. John Fitzgerald Moylan was appointed secretary of the committee. The committee issued an interim report last year which was reviewed in THE LANCET, Vol. II., 1909, p. 557. The present report, which is dated Dec. 31st, 1909, consists of an introduction, parts dealing with the office of coroner, jurisdiction of coroner, procedure and practice, miscellaneous matters, and a conclusion. It is signed by all the committee-men subject to a memorandum by Sir Thomas Bramsdon. It contains 46 sections, the majority of which consist of reasoned recommendations expressed in clear terms. We give herewith a summary of these sections, dwelling more fully on those that concern the medical profession than on those dealing with the purely legal position of the coroner and his non-medical functions.

I.—INTRODUCTORY.

The committee states that it has held 33 meetings and examined 69 witnesses, besides receiving answers to written inquiries from 275 coroners. It has considered further the questions of deaths resulting from the administration of anæsthetics and of the dangers arising from the use of flannelette in articles of clothing. Separate reports will be presented on these questions. The committee comments on the antiquated and obsolete condition of the law relating to coroners, and expresses its astonishment at the amount of good work which has been done in spite of it, and which can only be attributed to "the good sense, tact, and good feeling shown by the majority of coroners in their dealings with the public." The committee thinks the duties of the office would be more easily and efficiently performed if changes were effected in accordance with the following recommendations, the greater number of which "could be carried into effect by an enactment giving to some central authority a general power to make rules of practice and procedure."

II.—OFFICE OF CORONER.

1. *Statistics.—Franchise coroners.*—There are at present 330 coroners holding 360 coroners' jurisdictions. 200 are county coroners, 76 borough coroners only, and 54 franchise coroners only. Besides these all judges of the High Court are coroners *ex-officio*, although they do not exercise their function as such. It is recommended that the franchise coronerships should be abolished as vacancies occur, and their districts merged in the county coronerships. Special exceptions, as the coronerships for the City of London and the King's household, might require to be made. Instances are given of the inconvenience of franchise coronerships, which were created by Crown charters granted to individuals or corporations. Many of their jurisdictions form "islands" in the middle of county coronerships and confusion is thus created. Franchise coroners, moreover, have no *primâ-facie* right to appoint a deputy, which is inconvenient.

2. *Admiralty coroner.*—It is recommended that the offices of Admiralty coroner and his deputies, which have been in practical abeyance since the passing of the Judicature Act, should be abolished formally.

3. *Land qualification of county coroners.*—It is recommended that this qualification, which has become nominal, be abolished.

4. *Professional qualifications of coroners.*—It is recommended that no one should be eligible for the office of

[1] Part I., Report. Presented to Parliament by command of His Majesty. Cd. 5004. London: Eyre and Spottiswoode, Limited. Pp. 22.

coroner or deputy coroner unless he be a barrister, solicitor, or medical man, subject to the continued tenure of existing appointments.

5. *Remuneration.*—The existing rule under which borough coroners are paid by fees and travelling expenses for each inquest should be revised, and as in the case of county coroners they should be paid by salary subject to quinquennial revision. Such salary should take into account the number of preliminary inquiries held, for these often may entail more trouble and time than an actual inquest. Such a change is desirable because "it is not right to put a coroner in the position of having a pecuniary motive for holding unnecessary inquests." The same remark applies with greater force to the payment of the coroner's officer. In the larger courts a clerk to take depositions, and clerical assistance in the smaller courts, should be provided.

6. *Age limit.*—Retirement from the office of coroner should be compulsory at the age of 65, subject to one five years' extension by the Lord Chancellor for special reasons, and subject to the interests of existing appointments.

7. *Pensions.*—The office of coroner should accordingly be pensionable. Several reasons are given for this recommendation.

8. *Time for appointing borough coroner.*—Doubt exists as to the interval allowed before filling up a vacancy for the post of borough coroner. The committee suggests that this should be fixed at a maximum of not less than three months.

9. *Number of deputy coroners.*—A coroner should have power in an emergency to appoint a second deputy under conditions to be regulated.

10. *Certificate for deputy of borough coroner.*—No justice's certificate should be required, as at present, before the holding of an inquest by a deputy coroner. Reports should be made to the local authority of all occasions on which a coroner acts by deputy.[2]

11. *Coroners as justices of the peace.*—If the professional qualification recommended above be approved the committee recommends that the name of every county and borough coroner should be placed on the commission of the peace for reasons specified in this section.

III.—JURISDICTION OF CORONER.

12. *Fire inquests.*—The committee considers that the system of fire inquests established by the Act of 1888 in the City of London has worked so well that it might be extended to the country at large, possibly first as an adoptive Act[3] and later as compulsory. It would tend to deter incendiaries, to keep property owners up to the mark in taking precautions against fire, and to improve fire brigades.

13. *Treasure trove.*—The "attenuated" jurisdiction of a coroner with respect to treasure trove should be revised, to which end certain suggestions are made in this section.

14. *Coroner as substitute for sheriff.*—The jurisdiction of coroners to act on occasion as substitutes for sheriffs should be transferred to designated county courts. The present jurisdiction in this respect demands technical knowledge not possessed by a non-legal coroner.

15. *Post-mortem examination without inquest.*—The committee expresses its conviction that "it is most desirable that the coroner should, without holding an inquest, have power to order and pay for a post-mortem examination in cases of sudden death where the cause is unknown, and there is no reason to suspect that the death is violent or unnatural." The committee considers that this would almost certainly tend to the diminution of inquests and the consequent sparing of distress to the friends of many deceased persons.

16. *Deaths under anæsthetics.*—These will be considered fully in a later report. In the meanwhile it is submitted that "every case of death under an anæsthetic ought to be reported to the coroner, whether it occurs in a public institution or a private house. If the coroner on inquiry is satisfied that all due care and skill has been used it is undesirable that there shall be an inquest."

17. *Second inquest.*—Machinery should be created by which a coroner may move for and hold a second inquest when fresh facts not available at his first inquiry are brought to light. At present a second inquest is only held in reprobation of the coroner's conduct of the first inquiry.

[2] Sir Thomas Bramsdon dissents from this last recommendation.
[3] Sir Thomas Bramsdon being convinced that this Act would be beneficial would make it compulsory from the first.

IV.—PROCEDURE AND PRACTICE.

18. *Rules of procedure.*—The committee "think it essential that a wide and flexible power to make rules for procedure in coroners' courts should be given by statute to some central authority." It is suggested that this authority might be the Lord Chancellor and Home Secretary, assisted by a small advisory committee of coroners. A flexible power is necessary on account of the widely differing conditions existing between urban and rural jurisdictions with regard to accessibility of expert medical advice and other matters.

19. *Scales of costs.*—The committee thinks that "local scales of costs should be abolished and that the Home Secretary should prescribe scales of costs for coroners' courts." These should be uniform and money should be advanced to the coroner for their payment, subject to an auditor's surcharge.

20. *Exhumation.*—It appears to the committee that a coroner has sufficient power as a general rule to order an exhumation when necessary for the purposes of an inquest. A form of exhumation might be prescribed conveniently.

21. *Removal of body.*—It appears to the committee that for the purposes of an inquest the coroner has the legal custody of the body in question. It is recommended that he should be empowered to order the removal of a body for convenience of post-mortem examination to a hospital, even though outside the local limits of his jurisdiction. Adjoining districts might combine to maintain a joint coroners' court and mortuary.

22. *Warrants.*—Processes issued by a coroner to summon a witness should run in jurisdictions adjoining his own.

23. *Production of exhibits.*—Coroners should be entitled without question to order the production of material evidence of crime (exhibits) without applying for a Crown Office *subpœna duces tecum*.

24. *Jurors' list.*—The committee considers that service on a coroner's jury should carry exemption from service on other juries for a certain length of time. Coroners should retain their discretion in summoning juries.

25. *Number of jury.*—Not more than 12 jurymen should be sworn and the coroner should be empowered to accept a verdict of not less than three-fourths of the jury. Unanimity is not essential as the verdict is not conclusive for any legal purpose.

26. *Failure of jury to agree.*—If such a majority cannot be obtained the coroner should be empowered to discharge the jury and summon a fresh one.

27. *Perverse verdicts.*—However perverse or ridiculous a verdict may be the coroner should accept it, if the jury insist, but he should be empowered, if necessary, to apply to a judge in chambers to set the verdict aside and to authorise the summons of a new jury.

28. *Riders to verdicts.*—The committee recommends that riders should be required to be separated from verdicts and endorsed on the back of the inquisition, and that the coroner should be empowered to record his dissent from a rider and his reasons therefor.

29. *Medical witnesses summoned by jury.*—The committee considers that the powers conferred by the Coroners Act, 1887, upon juries to select a medical expert if they are dissatisfied with the evidence called by the coroner should be repealed, as they already have a remedy if the coroner does not conduct an inquest properly.

30. *Payment of jury.*—Juries should as a rule be paid and upon a uniform scale.

31. *View of the body.*—The witnesses examined by the committee were almost unanimous that the coroner's view of the body should be retained, since the law requires an inquest to be held *super visum corporis*, and since it may be necessary for his proper understanding and exposition of the medical evidence. The committee concludes that the view by the jury should be as a rule dispensed with, but that the coroner should be empowered to order it at any stage of the inquest, in which case it should be something more than the present usual "perfunctory march past."

32. *Fees to medical witnesses.*—The present fees of 1 guinea for a post-mortem examination and 1 guinea for medical evidence however often the inquest may be adjourned, are considered by the committee to be "wholly insufficient" and to give rise to "justifiable dissatisfaction" in the medical profession. The section continues:—

In many cases the post-mortem examination can be made effectively only by a pathological expert, but if such an expert be called in he can

at present receive only a guinea for the examination. For expert examinations both skill and practice are required, and the expert who makes them ought to be paid an adequate fee, not only for the examination but also separately for giving evidence. ..... There should be power to summon and pay the medical practitioner or practitioners with clinical knowledge of the case in addition to the expert. The provision of the Coroners Act, 1887, which includes the chemical analysis of the stomach or intestines as part of the post-mortem examination, is ridiculous, and should be repealed. Except in the simplest cases an analysis is useless unless it is made by a toxicologist with all the appliances of a modern laboratory at his command. ..... The conditions under which a coroner may order an expert analysis should be determined by Home Office regulations ..... (subject to) the powers of the Home Secretary to direct a special analysis by an expert named by him in special cases.

33. *Selection of medical witnesses.*—We quote a portion of this section as it deals with a much-debated matter.

The medical practitioner who was called in to see the deceased may or may not be the proper person to make the post-mortem examination. It is a matter which must be left to the absolute discretion of the coroner, who is the only person who can determine the fitness of the medical practitioner to make the examination. Every coroner should be empowered to call such medical witnesses as may be necessary for the proper determination of the case. ..... To give to coroners a somewhat wider discretion as to costs would, on the whole, be conducive to the efficiency of inquests and the public interest.

This section also describes with commendation the powers of the procurator fiscal in Scotland with regard to obtaining and paying for medical evidence.

34. *Medical fees in cases of institutions.*—The committee has been unable to obtain from any witness a defence of the existing provision whereby the medical officer of a "public hospital, infirmary, or other medical institution" is not paid for performing a post-mortem examination upon the body of a person dying in such institution, or for giving evidence at an inquest concerning his death, and thinks this "inequitable provision" should be repealed.

35. *Committals by coroner.*—The question of committing persons for trial for murder or manslaughter by coroners is considered, and it is suggested that the question be referred to high judicial authority.

36. *Depositions.*—A full note of all evidence at inquests should be taken by a clerk provided for the coroner.

37. *Copies of depositions.*—The committee considers that as the coroner controls a court of record the safe custody and control of depositions and other records should be ensured by rules, and a reasonable scale of costs for the supply of copies of depositions should be prescribed.

38. *Attendance of coroners at assizes.*—This is customary where it is required to prove depositions that have been made before the coroner. The committee thinks the practice inconvenient and unnecessary as a rule, and suggests an alternative procedure.

39. *Seals and parchment.*—The requirement that the inquisition in cases of murder or manslaughter should be recorded on parchment and sealed by the jury is inconvenient and unnecessary and should be abolished.

40. *Coroner's officer.*—This section explains that though the coroner's officer fulfils important functions in obtaining evidence and summoning witnesses and attending inquests, yet he is "unknown to the law." It approves of the common practice of nominating a police officer or ex-police officer for the office and giving his fee to the police fund and not to himself. This custom is recommended for universal adoption.

V.—MISCELLANEOUS.

41. *Consolidation.*—The committee recommends that a fresh Consolidation Act should be prepared, to include the 30 existing enactments dealing with the law of coroners in a single measure.

42. *Cremation cases.*—Dr. H. T. Herring's evidence in respect to inquests on bodies brought to this country for cremation is recommended to the attention of the Home Office.

43. *Certification of deaths.*—The committee condemns the present laxity of death certification and recommends that a certificate of death should not be accepted from a medical practitioner unless it states that he has satisfied himself of the fact of death by a personal inspection of the body, and also that registrars should be required by law to report all uncertified deaths to the coroner, as is now usually done.

44. *Verdict in cases of suicide.*—The verdict of *felo de se* should be abolished and the verdict of "temporary insanity" is open to grave objection. "In cases of suicide the verdict should simply be that the deceased died by his own hand (stating how). But the jury should be at liberty to add to their verdict that there is no evidence to show the state of his mind, or that at the time of taking his life he was of unsound mind."

45. *Open court.*—The committee approves of the present law which gives the coroner the same discretion to exclude the public (including representatives of the press) from his court as is possessed by examining magistrates. It again commends the Scottish system of private inquiry by the procurator-fiscal, except in cases of industrial accidents or deaths in prison, but adds that "the jury system is so deeply rooted in English life and history that we do not see our way to advocate any change."

VI.—CONCLUSION.

46. The committee points out that out of this considerable number of recommendations it attaches special importance to three: the abolition of franchise coroners, the payment of all coroners by salary instead of fees, and the bestowal on a central authority of a power to make rules of practice and procedure. Finally, it expresses its appreciation of the services rendered by Mr. J. F. Moylan, secretary of the Committee.

OBSERVATIONS ON THE CIRCULATORY SYSTEM.

BY HARRY CAMPBELL, M.D. LOND., F.R.C.P. LOND.,
PHYSICIAN, WEST-END HOSPITAL FOR DISEASES OF THE NERVOUS SYSTEM.

X.[1]

The Pulse.

THERE is a tendency in some quarters to belittle the digital method of examining the pulse. Nevertheless, if the necessary skill in manipulation has been acquired, valuable information can be obtained by it. So far as the estimation of the blood pressure is concerned, I indeed regard the fingers as in some respects superior to the hæmomanometer, and this in spite of the fact that I have systematically employed this instrument since its first introduction.

I hold with Dr. William Russell that, in judging of the value of an instrumental reading, the condition of the arterial wall has to be taken into account. While normal arteries in a state of moderate tonus may give accurate readings, the readings given by vessels thickened as the result either of disease or vaso-motor spasm are apt to be too high. If, as may happen in advanced granular kidney, we obtain a reading of 280 mm. Hg, the strong probability is that it is in considerable excess of the actual figure; and the like is true when with a flickering heart and barely perceptible radial pulse the hæmomanometer indicates so substantial a pressure as 90 mm. Hg. In each case, as Dr. Russell points out, the excessive record is to be explained by the supernormal resistance which the walls of the arteries offer to compression: in the one case the excessive resistance is the result of pathological thickening and spasm, and in the other case of spasm alone, the systemic arteries actively contracting upon, and thus accommodating themselves to, the ever-diminishing volume of systemic arterial blood.

In estimating blood pressure by the finger, on the other hand, the practised physician can make allowance, not only for the compressibility of the artery under examination, but also for the character of the pulse-wave. Yet so enamoured have some physicians become of the instrumental method of testing blood pressure that they even deny that the finger is of any use for this purpose, and they are prepared with learned arguments in support of this contention. It may safely be affirmed that such have never trained themselves in the digital method. Long before any instrument had been invented for measuring the blood pressure clinically, a definite connexion had been established between high blood pressure and renal disease, and assuredly many physicians have been put on the track of renal disease by the "feel" of the radial pulse. It has certainly happened to me many times that having felt a *plus* pressure radial pulse suggestive of chronic renal disease and cardiac hypertrophy, I have forthwith examined the cardiac apex only to find it displaced outwards, as I anticipated it would be. And I have further

[1] Nos. I., II., III., IV., V., VI., VII., VIII., and IX. were published in THE LANCET of Jan. 1st. (p. 48), 8th (p. 121), 15th (p. 193), 22nd (p. 256), and 29th (p. 318), Feb. 5th (p. 388), 19th (p. 521), and 26th (p. 590), and March 19th (p. 811), respectively.

found that with this easily recognised *plus* pressure one is generally safe in postulating a family history of apoplexy. Contrariwise, I have over and over again been able to verify with the finger Broadbent's dictum to the effect that a low pressure pulse is characteristic of long-lived families. I mention this as a further vindication of the digital method of examining the pulse.

It is astonishing how little pulse-testing has been taught in the medical schools. Before the introduction of the hæmomanometer it was all but entirely neglected. In my student days the examination of the pulse consisted of little more than the mere counting of it, and I do not remember to have received the slightest hint as to how to set about estimating blood pressure. This disappointed me not a little, as I fully realised the great importance to the physician of being skilled in this respect. Not until the appearance of the late Sir William Broadbent's book on the pulse was I able to obtain any definite and detailed information on this subject.

Broadbent taught that the blood pressure could be accurately estimated by noting the condition of the artery between the beats in regard to what he termed "fulness." If on placing the tips of two or three fingers on the radial artery, and moving them to and fro across the vessel, the latter gave to the fingers a sustained feeling of cylindricality, if, i.e., the artery felt like a solid cylinder both during and between the beats, it was said to be "full between the beats," and the pulse was regarded as a high tension pulse. If, on the other hand, this feeling of cylindricality was lost between the beats, the vessel seeming to melt away into the surrounding tissue, the pulse was judged to be of "low tension." In carrying out this method, however, a precaution (one which Broadbent omitted to indicate) has to be observed, otherwise it will give altogether wrong results. When I first employed the Broadbent method I was met with the difficulty that almost all the radial arteries I felt appeared "full between the beats," and this will be found to be always the case, even when the blood pressure is manifestly low, provided sufficiently light pressure is employed. To make Broadbent's method of practical use it is, in short, necessary to pay attention to the amount of pressure exercised by the examining fingers; that pressure must not be too great, nor too little, but of a moderate degree which experience alone can determine.

The art of testing the blood pressure digitally depends essentially upon the amount of pressure which is applied to the artery and the ability to estimate that amount correctly—in other words, it depends upon the delicacy of the muscular sense. This differs, of course, in different individuals. Some few are so well endowed in this respect that if properly instructed they can learn to estimate the blood pressure by the digital method in a comparatively short time; others may take years to acquire the necessary skill; others, again, never attain it. Even in the same individual proficiency may vary from time to time. When the body is exhausted or the hands are cold, the "tactus" loses in discriminating power. A common mistake in feeling the pulse is to employ too great pressure. Of the large number of students and others to whom I have offered my own for examination, but few have shown sufficient delicacy of manipulation; not infrequently the wrist has been grasped with truly Herculean vigour. No skill in testing the blood pressure can ever be attained in this way: a touch of the utmost delicacy must be employed.

While recognising the value of Broadbent's method I personally prefer the method of obliteration. This may be carried out in several ways. A plan which has some advantages is to use the fingers of one hand to obliterate the artery, and then, having with the third finger of the other obliterated the distal portion of the vessel so as to prevent "recurrence," to feel with the index finger of this hand for the disappearance of the pulsations. I prefer, however, the plan of making pressure upon the artery with a single finger, or with two or more fingers of one hand, and observing the degree of pressure needful to obliterate the pulsations as felt *under* the finger (or fingers). As the degree of pressure is increased a point is at length reached at which all sense of pulsation *under* the finger (or fingers) is lost, though remaining on the proximal *side* and also on the distal side if the pulse is decidedly recurrent. No account is to be taken of these proximal and distal pulsations. Attention is to be concentrated on the pulsations as felt under the finger (or fingers).

While examining the pulse the physician should, preferably, be sitting; he should as far as possible be in a rested condition of body, and his hands should not be cold. The patient's wrist should be kept level with, or only slightly above or below, his heart, and should rest on some firm support, such as the bed, or a table. It is very important to get the wrist in the best position for examination. The physician places two or three fingers of one hand over the radial artery, while with the other he gently flexes and extends the wrist and endeavours to obtain the position most favourable for isolating the artery. This will often be found to be a slightly extended position of the wrist. Meanwhile the condition of the arterial wall (in regard to tonus, thickening, dilatation, tortuosity, calcareous degeneration, &c.), should be ascertained as far as possible. The condition of the vessel in regard to its "fulness" or "emptiness" between the beats may then be tested by applying two or three fingers to it and exercising the gentlest possible pressure, and, while moving these fingers to and fro across the artery, very gradually increasing the pressure, and noting what degree of it can be applied before the sense of cylindricality disappears. During this procedure the patient's wrist may be gradually raised and lowered so as to modify the degree of hydrostatic pressure in the vessel, note being taken meanwhile of the effect of this upon the tension of the vessel wall.

By this time the physician will have duly prepared himself for gauging the degree of pressure needful to check the pulsation as felt *under* the examining finger (or fingers). Very gentle pressure should first be made, and this should gradually be increased until the pulsation disappears. As the pressure is increased the impulse of the pulse-wave under the finger becomes more and more pronounced until a maximum is reached, after which it gradually subsides and is finally lost. Contrariwise, when, after obliteration of the vessel, the pressure of the finger is gradually lessened, the faintest possible pulsation is at first felt, and this gradually increases to a maximum, after which it grows less and less, and ultimately dies down. This manœuvre of gradually increasing and diminishing the pressure should be gone through a few times. It matters little whether two or three fingers, or even a single finger, be employed in the examination; after due practice a single finger will be found to serve quite well. The pads of the finger-tips should be applied to the vessel, but if a single finger is employed, say the index finger (the thumb answers equally well), a considerable portion of the palmar surface may be laid lengthwise over the artery—e.g., the whole of the palmar surface belonging to the distal phalanx. The finger pad is so placed upon the vessel that the cessation of the pulsations, as felt by the finger at the moment the lumen is obliterated, and their renewal upon diminution of the pressure, are first felt in the central part of the pad.

If the finger is applied in this way and a gradually increasing pressure made with it, it will be found that the pulsations first become imperceptible in the central part of the pad and—I am now assuming that there is marked recurrency—that with every increment of pressure the pulsations recede in the proximal and distal directions of the vessel, leaving an ever-increasing portion of its length devoid of pulsation; and, contrariwise, that as the pressure on the obliterated vessel is diminished the proximal and distal pulsations gradually approach one another, and finally, at the moment when the flow through the vessel is re-established, meet at the centre. The fact that the pulsations subside and revive in this fashion, and that their cessation and revival are not felt instantaneously through the entire length of finger contact, is to be explained by the circumstance that, the finger-pad being convex, the maximum pressure is produced at its central part.

In the method just described the finger employed for feeling the pulsations also serves for exerting the pressure and estimating its extent. It is possible to employ the other hand for this purpose. The degree of pressure needed to obliterate the vessel may also be indicated by means of a bulb manometer placed over the examining finger, note being taken of the position of the index at the moment when the pulsations are interrupted.

The recurrent pulse.—When after obliterating the radial artery at the wrist a pulsation can be felt over the distal part of the vessel, as it lies external to the flexor carpi radialis, the phenomenon is known as the "recurrent pulse." The term sufficiently describes the condition; it is

due to the transmission of pulsations in a direction opposite to the normal—i.e., centrewards—by means of the collateral circulation, notably through the superficialis volæ and the anterior and posterior carpal. Some have regarded the recurrent pulse as indicative of high blood pressure. For me it has no clinical significance. It is curious that Sir William Broadbent should refer to this form of pulsation as though it were an exceptional phenomenon, when, as a matter of fact, it is all but constant. Evidently this careful observer only took account of the phenomenon when it was markedly developed, for on close examination its presence in a greater or lesser degree can be detected in the vast majority of cases. In order to test for it both hands should be employed. With one hand the radial artery is obliterated in the usual position, and with the other the distal portion of the vessel as it lies beside the flexor carpi radialis is tested by means of carefully graduated pressure. If anyone fails by this method to detect recurrent pulsation in the great majority of cases he may rest assured that he has made but small progress in the clinical manipulation of the pulse.

A clinical exercise in blood-pressure gauging.—A good exercise for acquiring skill in estimating blood pressure digitally is to test the radial artery while the wrist is being gradually raised and depressed between its highest and lowest positions. In this way the pressure in the radial can be made to vary through a considerable range, one, .e., represented by a column of blood some 5 feet in length, say, 100 mm. Hg. Suppose the vessel we are examining to be normal and the blood pressure to be moderate. It will be found when the wrist is held as high as possible above the level of the heart that the pulse is highly compressible; that the radial walls feel only moderately tense, that it is difficult to perceive fulness between the beats, and that the pulse-waves give to the examining finger the impression of weakness, as of blood flowing under low pressure. As the wrist is lowered the character of the pulse will be found to undergo a progressive change: the artery will be felt to become more and more incompressible, its walls to become more and more tense, the sense of fulness between the beats to become more and more pronounced, while the impression conveyed to the fingers by the pulse-waves will be one of steadily increasing force. If the wrist is suddenly raised and depressed between the two extremes these changes will be strikingly manifest.

Here, then, we have a means of altering the radial blood pressure by very small amounts, and of educating the finger to detect even minute differences. I am not contending that anyone can attain to such a degree of proficiency as to be able to distinguish differences in pressure as represented by a few inches of blood column, although the exceptionally gifted can probably come near to this, but I believe that most can in this way learn to detect differences of pressure as represented by foot-columns of blood, say, three degrees of diminishing pressure as the wrist is raised from the mean position to its highest point, and three degrees of increasing pressure as it is lowered from the mean position to its lowest point.

A standard of comparison.—In estimating the blood pressure by the fingers it is a help to have some standard of comparison, and no better can be obtained than that offered by the physician's own pulse. He ought to know his average blood pressure and to be able to detect, digitally, any marked departure from it. If he has any difficulty in coming to a decision regarding a patient's pulse, he should from time to time examine his own, altering the level of the wrist as just described; the pulses of other persons, should they be available, may, sometimes also with advantage, be tested for comparison. In this way the tactus of the fingers can often be worked up to the necessary degree of refinement.

Proficiency in the digital method rarely met with.—I believe it to be possible for most medical men to acquire, by the methods described, sufficient skill in manipulating the pulse for ordinary clinical purposes. I am bound to say, however—I do so in fear and trembling—that in my experience but few possess the needful proficiency. Those who talk glibly of *plus* and *minus* pressures, after laying their fingers upon the patient's wrist, but too often show themselves incompetent to form even an approximate estimate of the pressure. It is this incompetence which leads many to under-estimate the value of the digital method and wholly to discard it in favour of the hæmomanometer. Finding that the results obtained by the finger test are not confirmed by the readings of the hæmomanometer, they at once assume that the fingers are useless for testing blood pressure, ignorant of the fact that the fault is not in the digital method, but in their way of applying it. As a matter of fact, the educated finger will probably make fewer mistakes than the hæmomanometer. It may safely be said that a skilled employer of the digital method would never make the mistake of greatly over-estimating pressure; whereas it is certain that the readings furnished by the hæmomanometer are sometimes in considerable excess of the actual pressure.

Faulty treatment based on a wrong estimate of the blood pressure.—Lack of skill in manipulating the pulse is frequently responsible for errors in treatment. A common mistake is to underestimate the strength of the pulse, especially in acute disease, and to order alcohol, digitalis, strychnine, or what not, to stimulate a heart which is thought to be failing, but which has, in point of fact, considerable reserve of force. I have myself seen this mistake so frequently that I can have no doubt that it is a very common one. Unless there are clear indications that the heart is failing it is worse than useless to worry it with drugs. If there are threatenings of imminent failure, stimulating measures should of course be adopted, but I am convinced that in the failure resulting from acute disease far more help can usually be obtained by such measures as restricting the diet, bleeding, oxygen inhalations, and saline injections, than by adding to the supply of toxins, already too plentifully present in the blood. In regard to alcohol it should be remembered that its action is evanescent and that consequently its chief use is in tiding the patient over a crisis. A not uncommon error, and a very grave one from the therapeutic standpoint, is to mistake a supernormally high-pressure pulse for a feeble one. This mistake is most likely to occur when the radial is small from extreme hypertonus and deeply imbedded. Only by making firm pressure on it is the excess of pressure in such cases revealed. A mistake here is serious, because there is no more valuable clue to treatment than the discovery of a supernormal pressure.

Large hypotonic radial artery with plus blood pressure.—Two opposite conditions of the radial artery are met with in subjects presenting persistently high blood pressure. The vessel may be habitually hypertonic, when it remains small and straight; or it may be habitually hypotonic, when it becomes dilated, tortuous, and greatly thickened. We have seen that high blood pressure is essentially due to generalised arteriolar contraction, and that with this contraction of the arterioles there tends to take place a protective contraction of the arteries proximal to them. The effect of this is to prevent the pre-arteriolar vessels from yielding under the heightened pressure and thus becoming dilated and tortuous: when the radial artery is thus protected by persistent hypertonus it remains small and straight in spite of continued high blood pressure. Chronic generalised arteriolar constriction is, however, not always accompanied by a contraction of the pre-arteriolar vessels. These latter may remain but moderately contracted, or even hypotonic, either generally or locally, in which case they undergo a progressive yielding and compensatory thickening. Hence it happens that if the radial arteries in a subject of persistently high blood pressure fail to share in the generalised hypertonus of the arterioles, they become dilated, tortuous, and greatly thickened. We must, then, be prepared to meet with two widely-differing types of radial artery in subjects of persistently high blood pressure—the small, straight vessel, moderately thickened, and the dilated, tortuous and highly thickened vessel. Not only may the radial artery, in consequence of persistent hypertonus, remain small and straight during many years of habitual high pressure, but it may, *per contra*, in consequence of persistent hypotonus, actually become dilated, tortuous, and thickened in subjects of habitual low pressure.

Widespread arterial thickening in subjects of habitual moderate pressure.—Sir Clifford Allbutt has pointed out that widespread arterial thickening is not infrequently met with in persons whose blood pressure is habitually moderate. This should not surprise us seeing that thickening of vessels does not necessarily increase the resistance which they oppose to the blood flow; changes in peripheral resistance are, as we have seen, essentially determined by the arterioles, and so long as a generalised arteriolar hypotonus

prevails blood pressure will remain low, even though considerable thickening of the arteries be present. As to the pathology of the arterial thickening in these cases, nothing is certainly known. We may assume that the cause is always some kind of irritation of the tissues constituting the vessel walls. Doubtless this irritation may sometimes be due to poisons acting directly upon the vascular tissues; but I believe that in many cases it results from chronic hypotonus in the manner already described. We have seen that so long as the muscular media is firmly contracted the intima, adventitia, and connective tissue, and perhaps even the yellow elastic tissue of the media, are entirely relieved from mechanical strain, the muscular fibres of the media being the sole elements in the vessel wall to be put on the stretch; but that when the muscle fibres relax all the elements of the vessel wall are stretched by the blood pressure, and that this leads to hyperplasia of the connective tissue, and to dilatation and often tortuosity of the chronically hypotonic vessels. I can have little doubt that this is the mechanism of the arterial thickening of at least many of the cases belonging to the class referred to by Sir Clifford Allbutt. This physician has been struck by the frequent occurrence of large, tortuous, and thickened radial vessels among peasants in whom the habitual blood pressure is not excessive. I suggest that in these cases the arterial changes occur as the result of the protracted radial hypotonus induced by long-continued manual labour; and I may mention in support of this view that I have noticed that in those who employ the right hand in labour more than the left the right radial displays a greater tendency to dilatation, tortuosity, and thickening than the left.

The relative size of the radial artery and the hand.—There is a fairly constant relation between the size of the radial artery and of the hand: when the hand is small the radial artery is small; when it is large the artery is large also. The largest radial arteries I have encountered belonged to an acromegalous man. Most men engaged in hard manual labour have large thickened radials; in leisured women these vessels are usually small.

Loss of vascular contractibility through vascular degeneration.—It is assumed by some physicians that as the arterioles undergo degeneration from senile decay and other causes their contractibility becomes greatly impaired, and that they are rendered correspondingly incapable of regulating local blood-supply in response to local requirements. Doubtless there is some ground for this assumption, but that the arterioles *as a whole* are ever gravely hampered in this respect is extremely doubtful. We may see patients in the latest stages of granular kidney capable of turning red and pale under slight provocation, and assuredly there has never yet existed a human being insusceptible of shock—that condition, i.e., in which a widespread arteriolar dilatation (chiefly in the splanchnic area) leads to a dangerously sudden rush of blood into the veins. No matter how degenerate the blood-vessels it is still by the ever-vigilant tonus of the arterioles that the blood is prevented from rushing with fatal facility into the veins; and in none is arterial degeneration so great but that a sudden and widespread failure in this function will cause the most "plethoric" person instantly to turn pale as death and to fall down unconscious.

That the degeneration of the muscular elements of the blood-vessels can never proceed beyond a certain degree is further evident from a consideration of the part they play in preventing the blood-vessels from undergoing a progressive yielding before the blood pressure. Any serious interference with this function of the vascular media would inevitably lead to such dilatation and thickening of the blood-vessels that death would soon result. We may, therefore, feel assured that a considerable functional capacity on the part of the muscular elements of the blood-vessels is absolutely essential to the continuance of life.

Abnormal arterial pulsation.—Sometimes arterial pulsation is so pronounced as to obtrude itself upon the notice of the patient—he feels a throbbing or beating where nothing of the kind should be felt. The area over which the throbbing is felt may vary considerably in extent: it may be limited to a narrow area—e.g., one temple or the epigastrium—or it may seem to involve the entire body. Such generalised pulsation is felt normally after violent muscular effort—e.g., sprinting—but it sometimes occurs "idiopathically" as a morbid phenomenon. In these cases the pulsation is most felt in the head, neck, chest, and abdomen, in the two latter regions being, of course, largely referable to the heart itself.

Arterial throbbing may be due to two causes: (*a*) powerful action of the heart causing an exceptionally large charge of blood to be driven into the arteries with each ventricular systole; and (*b*) arterial hypotonus allowing the vessel wall to yield with more than usual readiness before the pulse waves.

Localised throbbing is always due to the latter cause, but generalised throbbing may be due to one or other, or to both of these causes.

The generalised throbbing which results from muscular exertion is essentially cardiac in origin. I doubt whether arterial hypotonus takes any share in it. That the powerful contractions of the heart which result from muscular exertion are accompanied by a widespread relaxation of the systemic arterioles, notably those belonging to the muscles, is certain. Did such relaxation not take place the systemic arteries would very soon get over-distended and the left ventricle cease to deliver its normal quantity of blood into the arteries, with the result that pulmonary engorgement would inevitably ensue. Doubtless some relaxation of the vessels proximal to the arterioles also occurs. How far backwards this relaxation extends—whether, e.g., it involves arteries as large as the brachial—I cannot say, but that the relaxation is not shared by the largest arteries we may, I think, affirm with some confidence.

Consider for a moment how great is the strain to which the aorta is subjected during sprinting, when the left ventricle pumps much more than its usual charge of blood, at three times its usual rate of beat, into a greatly distended aorta. Assuming the aortic muscle fibres to relax under these circumstances, all the tissues of the aorta, including the thin adventitia, would take an equal share in the strain, and the muscle fibres of this vessel would fail in what I, at least, believe to be their essential, if not their sole, function—that, namely, of relieving by their active contraction the strain on the other tissue elements of the vessel wall. I should therefore expect the aortic muscle fibres, far from relaxing, to increase in tonicity during augmented cardiac action.

It might be argued against this view that a hypertonic aorta would not yield with sufficient readiness to receive the successive charges of ventricular blood. It must, however, be remembered that as regards the extensibility of its muscular coat the aorta stands in a very different category from the smaller arteries, such as the radials, and still more the arterioles. Not only is its muscular equipment comparatively slender, but by reason of its large bore its walls (in accordance with the formula $t = pr$) are subjected to much greater tension than are those of the smaller vessels; the tension in the aortic walls must be at least ten times that in the radial walls. Hence it happens that while an artery like the radial, when thrown into complete hypertonus, can maintain the lumen of the vessel at its practical minimum under the highest blood pressure compatible with life, the aorta, even though hypertonic, would yet yield readily to receive the ventricular blood, for it must not be forgotten that contracted muscle fibre is highly extensile provided the extensile force be adequate. My own belief is that the augmented cardiac action resulting from muscular exertion is the signal for augmented contraction on the part of the aortic muscle fibres, and that by their vigorous contraction (possibly increasing in strength with every increment in the distension of the aorta) they oppose a resistance *sui generis* to super-distension, thus relieving the strain upon all the other aortic tissues.

I conclude, then, that the arterial pulsations which are felt as the result of muscular exertion are essentially cardiac in origin, that they result from the rapid discharge into the aorta of unusually large charges of blood, and that arterial relaxation takes little or no part in their causation. Possibly the generalised pulsations which are occasionally felt in connexion with functional palpitation may sometimes own a like causation; as a rule, however, in this form of palpitation the heart pumps less than the average quantity of blood into the arteries with each beat.

So much for arterial pulsation due to heightened cardiac action. Let us now consider that form of it which results from arterial hypotonus. This variety is generally limited to particular vascular areas. We do, however, occasionally

meet with cases in which the patient complains of "throbbing all over," although there is no evidence of augmented cardiac output. Such cases can only be accounted for on the assumption that there is a widespread arterial hypotonus, in which, however, the arterioles evidently cannot share, inasmuch as a generalised arteriolar hypotonus would lead to a dangerous fall in blood pressure. Occasionally patients with Graves's disease complain of throbbing "all over the body," and there is no evidence that the individual systolic outputs of the heart are augmented in the tachycardia which accompanies this affection. We must assume that the throbbing in these cases is due to hypotonus of the larger arteries. So far as the radial arteries are concerned they are, in my experience, generally contracted in Graves's disease.

Throbbing of the head and neck from hypotonus of the carotids and their main branches is by no means rare; it may, or may not, be accompanied by hypotonus of the arterioles of the skin of the face, nose, ears, and neck, singly or together. If the small arteries in the neighbourhood of the middle and internal ear share in the dilatation, the patient may hear the pulsations, especially when the side of the head rests on a solid support such as a pillow. If the retinal arterioles dilate, pulsatile waves may be communicated to the field of vision. The question whether the arterioles of the brain ever share in this dilatation is purely speculative. One is tempted to assume that they may sometimes do so, because it not infrequently happens that "a rush of blood to the head" is attended with mental confusion. Such a rush of blood to the head often occurs as part and parcel of an ordinary flush storm. It may also occur in overfed plethoric persons, especially if in addition to the plethora the blood pressure is high and there is a tendency to nose-bleeding. I am in a position to affirm from considerable experience that cases of this kind can often be much relieved, if not cured, by such means as purgation, bleeding, and above all restriction of the diet. The varieties of flushing of the face from vaso-motor causes are too numerous to be discussed here in detail, but the simple emotional flush, that which occurs after a meal, and the facial flush which occurs as part of the flush storm, may be mentioned.

I have seen the whole of the head, neck, and chest so markedly flushed in Graves's disease as to suggest scarlet fever. I have known a man to be attacked for hours together with such violent flushing of the head and neck, accompanied by exaggerated pulsations, as to make the skin appear as red and turgid as a cockscomb. The patient was a brilliant, highly neurotic student, whose career was entirely destroyed by this misfortune. When we reflect how slight must be the central vaso-motor change to cause arterial hypotonus or the reverse, the wonder is rather that morbid vaso-motor phenomena are not more common than they are.

Pulsating aorta.—One of the most familiar forms of arterial throbbing due to hypotonus is afforded by the phenomenon known as "pulsating aorta." There is marked pulsation in the abdomen, especially in the epigastric region. In this connexion it must not be forgotten that in the upper part of the epigastrium the aorta belongs to the thoracic portion, lying as it does behind the diaphragm: a point midway between the sterno-xiphoid articulation and the umbilicus marks the beginning of the abdominal aorta.

This hypotonic form of aortic pulsation is frequently met with in highly nervous women. It is generally attended with tachycardia and other evidence of cardio-vascular irritability. The patients are often thin, so that the vessel can readily be isolated and felt as a tube about the thickness of a stout ruler undergoing violent shock-like pulsations. The condition is so frequently mistaken by the student for aneurysm that Sir William Jenner formulated the well-known aphorism, "The last thing to be thought of in morbid epigastric pulsation is aneurysm"; but these cases should present no difficulty in diagnosis, for apart from the rarity of abdominal aneurysm as compared with this functional form of pulsation, in the latter condition careful examination generally discloses the normal tubular shape of the aorta.

* * * * * * *

Here I am led to conclude these articles. I am, indeed, far from having exhausted my subject, but I feel I have already trespassed too largely on the indulgence of the Editor.

MOTORING NOTES.

BY C. T. W. HIRSCH, M.R.C.S. ENG., L.R.C.P. LOND.

Should a Medical Man Drive His Own Car?

IN a medical contemporary a practitioner raises this question, and remarks that driving from one patient's house to another the thoughts and attention which should be occupied with the contemplation of the cases under treatment are instead diverted to the management of the car, to the detriment of the patient's interests. Of course, this objection, if it exists, which I question, is solved by employing a chauffeur. Personally, with a good many medical motorists, I find that driving myself makes me fresher and keener to undertake each case as it is approached. It is also a common experience that driving and steering when indulged in daily become automatic, and really leave the brain free for turning over the points of one's "cases." Another point which has been raised is whether driving interferes with the manual dexterity needed for surgical operations. Those consulting surgeons to whom I have spoken on this subject assure me that such is not the case, and both my colleagues and myself on the staff of a local cottage hospital, where we do a considerable amount of operative work, are of the same opinion.

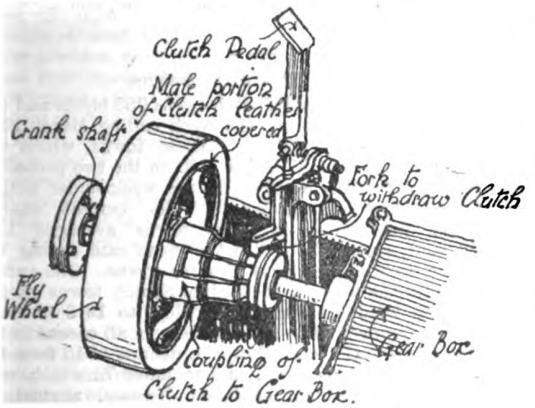
Concerning Horns.

Some form of warning signal must, of course, be carried on all cars, and it certainly seems reasonable that medical men of all people should employ a "road clearer" that does not give offence to anyone. Electrical "buzzers" need accumulators and cannot be quite classed as "musical"; the ordinary horn comes under the same objection as to sound, and in addition the reeds may break or the bulbs may perish, though the fitting of a leather cover prolongs the life of the latter. A real novelty is the "testophone," which gives a multi-note musical signal, is light in weight, and is easy of attachment. A popular instrument is the "Gabriel" horn, which should be fitted against the side of the car, and is operated by the waste exhaust gases. Usually a small foot pedal, placed in a convenient position on the floor of the car, works the horn, but if preferred a Bowden wire attachment, with a hand lever for fixing to the steering column, can be supplied. For small cars up to 10 h.p. the No. 1 size is suitable, and for larger cars the No. 2 or 3. In attaching it is advisable not to place the valve too near the engine where the exhaust is likely to be too quick. The place suggested is at the outer end of the muffler and good quality 1-inch steam hose must be used for leading the exhaust from the valve to the horn.

A Useful Touring Map.

Messrs. A. Duckham and Co., Limited, have issued a section map of England and Wales consisting of some 50 parts. It is to the scale of eight miles to the inch, and is quite up to date, so that the roads marked in red may be relied upon as being good motoring roads. An index map, numbered and marked in the same way as the various sections, is included, so that the portions needed for any given tour may be readily selected.

The Cost of Motoring Guaranteed.



The London Motor Garage Company, Limited, of 33–37, Wardour-street, London, W., have recently sent me particulars of their hire-purchase, up-keep, and maintenance agreements. They provide and pay wages of a competent driver, maintain in good order, and provide all necessaries for running various powered Charron cars for a fixed sum per year, varying from £375 for a 8–10 h.p. car to £480 for a 16–22 h.p.; this includes insurance, providing another car should the customer's car break down, and allows for travelling 6000 miles in the year, beyond which an excess per mile is charged.

The Motor Maintenance Company of 11 and 12, Weymouth-mews, London, W., also issue inclusive maintenance contracts, covering every expense connected with the car, and varying in cost according to the horse-power, from £200 to £350 per annum.

Clutches and their Idiosynorasies.

A large number of cars are still manufactured, and rightly too, I believe, with the leather-faced coned friction form of transmitting the power from the engine to the gearbox.

Practically in all these kinds the fly-wheel is hollowed out to receive the male part, which latter, by some form of coupling, is connected to the first motion shaft in the gear-box, as shown in the accompanying sketch. In some patterns the male part recedes from the female, in others the female from the male, while in another variety the male disengages by pushing forward in lieu of being pulled back, but in all of these the principle is the same. A powerful spring, or on some cars several springs keep the two parts in contact, and a lever worked by a pedal, of either the piano "push down" kind or one of the now more popular "push forward" forms, allows of the separation of the male from the female portion. It is, of course, essential that the clutch should always

permit of the engine being disconnected from the transmission gear, and also that the engagement should be gradual, otherwise there may be a jar on the transmission gear and consequent damage. Those who have had cars will, I am sure, on consideration, agree with this aphorism: "Most breakdowns, after putting aside those due to ignition torts (which now that the high-tension magneto is the general method of exploding the mixture are not as prevalent as they used to be), are the result of a fierce clutch, and could therefore have been avoided by the application of collan or castor oil." The old saying that there is nothing like leather seems to apply to clutches, and certainly dressed harness leather, previously soaked in castor oil, cut from the thickest part of the butt, answers admirably, provided it is of the same thickness throughout, put on well stretched in segments, with the ends butted and scarfed, and with the screws or fixing rivets countersunk, so that, even if the leather does wear, they do not project, and with the ends of the screws or rivets on the inner side of the cone riveted over so that they may not work loose. In order that the leather surface may be quite true it is usually spun in the lathe, and even then there may be fierceness. To overcome this many makers fit three or four buffer springs under the leather, equally distant apart from one another, so as to cause a slight bulging, which is gradually overcome as the clutch engages, so that the male and female parts do not become locked too suddenly. I noticed recently another method of achieving this result at Messrs. Hobson's on their Delahaye car, in which beneath the leather is a rubber ring all round the clutch, which becomes compressed as the male part enters, and so effects the same result. Another cause of this objectionable condition is the stiff working of the mechanism that withdraws the male member, for if it is in some part too tight, from want of lubrication or other cause, the clutch movement may not follow the driver's foot, and so the letting in of the clutch is done in a series of small jerks. This also happens if the leather has irregularities or "atheromatous patches" on its surface. Castor oil or collan oil makes the leather softer and cures slight cases; severe ones need the surgeon's knife, as represented by a spin in the lathe. Lubrication and attention to the moving parts will remedy the former complaint. The objection to leather is that if it becomes too greasy the clutch may slip, which is nearly as bad as too fierce a clutch. To have the engine pulling well and not to be able to transfer its power to the wheels is annoying. On a hill, if a sprag is not fitted and the brakes are out of order, it is even more serious than hurtful to one's pride, for it may necessitate the treatment of the driver as well as of the car. Keeping the leather free from excess of grease, and dusting fuller's earth on if it is too oily, will generally prevent these troubles, or if the slipping is the result of too weak a clutch spring the tension can be increased, if, as is now the rule, an adjustment is fitted, or, if there is none, the spring may be made stronger by packing it up with washers. A good substitute for leather, and one, too, which will hold, no matter how oily it may be, is Frood's patent fibre. Practically every motor-bus in London uses this material for its clutches as well as brakes.

The Ferodo and Bonded Asbestos Fibres are water- and grease-proof. They have a high coefficient of friction, and from experiments recently made by Professor Ernest Walson in the Siemens Electrical Engineering Laboratory at King's College, London, there is no question that they are, as the motor-buses have discovered, ideal substances for friction clutches and brakes. The Herbert Frood Company, Limited, of Sovereign Mills, Chapel-en-le-Frith, will, I understand, be pleased to line any clutch sent, provided they are informed as to the thickness needed, and in that case only the male part need be sent. Clutches made of this material work well, are not fierce, do not burn, and are unaffected by oil. They need an occasional application of graphite grease.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN 76 of the largest English towns 8379 births and 4323 deaths were registered during the week ending March 19th. The annual rate of mortality in these towns, which had steadily declined in the six preceding weeks from 17·0 to 13·6 per 1000, did not exceed 13·5 in the week under notice. During the first 11 weeks of the current quarter the annual death-rate in these towns averaged 15·1 per 1000; the mean rate in London during the same period was also equal to 15·1. The lowest reported annual rates of mortality in the 76 towns were 3·9 in Rotherham, 4·3 in King's Norton, and 5·8 in Hornsey and in Handsworth; the rates in the other towns ranged upwards, however, to 19·2 in Ipswich, 19·4 in Great Yarmouth, 24·2 in Huddersfield, and 27·1 in Rochdale. In London the recorded death-rate did not exceed 13·2 per 1000. The 4323 deaths registered in the 76 towns during the week showed a further decline of 38 from the numbers returned in recent weeks, and included 334 which were referred to the principal epidemic diseases, against 328 and 289 in the two preceding weeks; of these 334 deaths, 134 resulted from whooping-cough, 83 from measles, 38 from diarrhœa, 36 from diphtheria, 31 from scarlet fever, and 12 from enteric fever, but not one from small-pox. The mean annual rate of mortality in the 76 towns in the week from these epidemic diseases was equal to 1·0 per 1000, against 0·8, 1·0, and 0·9 in the three preceding weeks. No death from any of these epidemic diseases was registered in East Ham, Hornsey, St. Helens, Rochdale, York, or in nine other smaller towns; the annual death-rates therefrom ranged upwards, however, to 3·1 in Devonport, 3·3 in Barrow-in-Furness, 3·8 in Hastings, and 4·8 in Ipswich. The fatal cases of whooping-cough in the 76 towns, which had been 112 and 122 in the two preceding weeks, further rose to 134 in the week under notice, and caused annual death-rates equal to 1·3 in Birkenhead and in Newport (Mon.), 1·9 in West Hartlepool, and 2·5 in Devonport and in Barrow-in-Furness. The deaths from measles, which had been 88 and 45 in the two previous weeks, rose again to 83; the highest death-rates from this disease during the week were 1·5 in Stockport and in Burnley, 2·2 in Hanley, 3·8 in Hastings, and 4·1 in Ipswich. The 38 deaths attributed to diarrhœa showed but a slight increase upon the numbers in recent weeks. The fatal cases of diphtheria, which had been 49 and 32 in the two previous weeks, were 36 in the week under notice, and included 10 in London and its suburban districts, 5 in Manchester, 3 in Nottingham, and 2 both in Birmingham and in Burnley. The 31 deaths from scarlet fever were fewer by three than those in the previous week; 6 occurred in London, 4 in Birmingham, 4 in Liverpool, and 4 in Manchester and Salford. Only 12 deaths were referred to enteric fever

in the 76 towns during the week. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had declined in the 22 preceding weeks from 2819 to 1754, had further fallen to 1713 on March 19th; 180 new cases of this disease were admitted to these hospitals during the week, against 211 and 199 in the two preceding weeks. The Metropolitan Asylums Hospitals contained no case of small-pox on March 19th. Of the 1231 deaths registered in London during the week under notice, 238 were referred to pneumonia and other diseases of the respiratory system, against numbers declining steadily from 425 to 279 in the five preceding weeks; these 238 deaths were 173 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 30, or 0·7 per cent., of the deaths registered in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death during the week were duly certified in Leeds, Bristol, Bradford, Newcastle-on-Tyne, Hull, Nottingham, Leicester, and Salford, and in 52 other smaller towns; the 30 uncertified causes of death in the 76 towns included 5 in Liverpool, 3 in London, 3 in St. Helens, and 2 each in Birmingham, South Shields, and Gateshead.

In 76 of the largest English towns 7755 births and 4448 deaths were registered during the week ending March 26th. The annual rate of mortality in these towns, which had steadily declined in the seven preceding weeks from 17·0 to 13·5 per 1000, slightly increased to 13·9 in the week under notice. During the first 12 weeks of the current quarter the annual death-rate in these towns averaged 15·0 per 1000; the mean rate in London during the same period was also equal to 15·0. The lowest reported annual rate of mortality in the 76 towns during the week were 4·2 in Hornsey, 6·8 in King's Norton, 7·7 in East Ham, and 7·8 in Willesden, all being suburban districts; the rates in the other towns ranged upwards, however, to 19·8 in Huddersfield, 20·3 in Tynemouth, 20·4 in Grimsby, 21·3 in Stockport, and 23·7 in Swansea. In London the recorded death-rate last week did not exceed 13·5 per 1000. The 4448 deaths registered in the 76 towns during the week showed an increase of 127 upon the number in the previous week, and included 317 which were referred to the principal epidemic diseases, against 289 and 335 in the two preceding weeks; of these 317 deaths, 134 resulted from whooping-cough, 78 from measles, 42 from diphtheria, 29 from scarlet fever, 19 from diarrhœa, and 15 from enteric fever, but not one from small-pox. The mean annual rate of mortality in the 76 towns during the week from these epidemic diseases was equal to 1·0 per 1000, and corresponded with the rate in the previous week. No death from any of these epidemic diseases was registered last week in Brighton, Norwich, Derby, Halifax, York, or in 13 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·2 in South Shields, 2·4 in Liverpool, 2·5 in Stockport, and 4·5 in Hanley. The fatal cases of whooping-cough in the 76 towns, which had increased from 100 to 134 in the four preceding weeks, were again 134 in the week under notice, and caused annual death-rates equal to 1·3 in West Hartlepool and in South Shields, 1·5 in Hastings, and 1·6 in Barrow-in-Furness. The 78 deaths from measles showed a decline of 6 from the number in the previous week; the highest death-rates from this disease during the week were 1·3 in Merthyr Tydfil, 1·5 in Burnley and in Stockport, and 3·0 in Hanley. Of the 42 deaths referred to diphtheria, showing a slight increase on the numbers in the two preceding weeks, 15 occurred in London and its suburban districts, 3 in Manchester and Salford, and 3 in Hull. The fatal cases of scarlet fever, which had been 34 and 31 in the two previous weeks, further declined last week to 29, and included 10 in London, 5 in Liverpool, 4 in Manchester and Salford, and 3 in Blackburn. The 19 deaths attributed to diarrhœa were fewer than in any previous week of this year. The 15 deaths referred to enteric fever only exceeded by 3 the low number in the previous week; 6 were returned in London and 2 in Salford. The number of scarlet fever patients under treatment in the metropolitan asylums and in the London Fever Hospital, which had steadily declined in the 23 preceding weeks from 2819 to 1713, had further fallen to 1650 on March 26th; 173 new cases of this disease were admitted to these hospitals during the week, against 211, 199, and 180 in the three preceding weeks. The metropolitan asylums hospitals contained no case of small-pox on March 26th. Of the 1263 deaths registered in London during the week under notice 261 were referred to pneumonia and other diseases of the respiratory system, showing an increase of 23 upon the low number in the previous week, but were 121 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 36, or 0·8 per cent., of the deaths registered in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death during the week were duly certified in Leeds, Bristol, Bradford, West Ham, Newcastle-on-Tyne, Nottingham, Leicester, Salford, and in 49 other smaller towns; the 36 uncertified causes of death in the 76 towns included 8 in Liverpool, 4 in Preston, and 3 both in Birmingham and in Manchester.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 953 births and 612 deaths were registered during the week ending March 19th. The annual rate of mortality in these towns, which had been equal to 16·3 and 17·2 per 1000 in the two preceding weeks, declined again to 16·9 in the week under notice. During the first 11 weeks of the current quarter the annual death-rate in these towns averaged 17·6 per 1000, and exceeded by 2·5 the mean rate during the same period in the 76 largest English towns. The annual death-rates for the week in these eight Scotch towns ranged from 15·1 in Edinburgh and in Paisley, to 19·8 in Leith and 22·1 in Dundee. The 612 deaths from all causes in the eight towns during the week showed a decline of 10 from the number in the previous week, and included 72 which were referred to the principal epidemic diseases, against 79 and 82 in the two preceding weeks. These 72 deaths were equal to an annual rate of 2·0 per 1000; the mean death-rate from the same diseases in the 76 English towns did not exceed 1·0 per 1000. These 72 deaths in the Scotch towns included 35 from measles, 12 from diarrhœa, 10 from whooping-cough, 8 from diphtheria, 4 from scarlet fever, and 3 from "fever," but not one from small-pox. The fatal cases of measles in the eight towns, which had been 40 and 46 in the two preceding weeks, declined to 35 in the week under notice, of which 20 occurred in Glasgow, 6 in Dundee, 5 in Greenock, and 3 in Leith. The 12 deaths attributed to diarrhœa corresponded with the number in the previous week, and included 5 in Glasgow, 3 in Edinburgh, and 2 in Dundee. The 10 fatal cases of whooping-cough were fewer by 2 than those in the previous week; 6 were returned in Glasgow and 3 in Edinburgh. The deaths referred to diphtheria, which had been 12 and 5 in the two preceding weeks, rose again to 8 in the week mentioned, of which 5 were returned in Glasgow and 2 in Aberdeen. The 4 fatal cases of scarlet fever were within 1 of those in the previous week; and the 3 deaths referred to "fever" included 2 in Glasgow and 1 in Perth. The deaths in the eight towns referred to diseases of the respiratory system, which had been 114 and 107 in the two preceding weeks, further declined in the week under notice to 100, and were 87 below the number returned in the corresponding week of last year. The causes of 9, or 1·5 per cent., of the deaths in the eight towns were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death did not exceed 0·7 per cent.

In eight of the principal Scotch towns 850 births and 556 deaths were registered during the week ending March 26th. The annual rate of mortality in these towns, which had been equal to 17·2 and 16·9 per 1000 in the two preceding weeks, further declined to 15·3 in the week under notice. During the first 12 weeks of the current quarter the annual death-rate in these towns averaged 17·4 per 1000, and exceeded by 2·4 the mean rate during the same period in the 76 largest English towns. The annual death-rates for the week in these eight Scotch towns ranged from 12·3 and 12·6 in Edinburgh and Perth, to 20·2 in Dundee and 21·3 in Greenock. The 556 deaths from all causes in the eight towns during the week showed a further decline of 56 from the numbers returned in the two preceding weeks, and included 77 which were referred to the principal epidemic diseases, as against 82 and 72 in the two previous weeks. These 77 deaths were equal to an annual rate of 2·1 per 1000; the mean death-rate from the same diseases in the

76 English towns last week did not exceed 1·0 per 1000. These 77 deaths in the Scotch towns included 45 from measles, 9 from diarrhœa, 8 from whooping-cough, 6 from scarlet fever, 6 from diphtheria, and 3 from "fever," but not one from small-pox. The fatal cases of measles in the eight towns, which had been 46 and 35 in the two previous weeks, rose again to 45 in the week under notice, of which 19 occurred in Glasgow, 9 in Dundee, 7 in Greenock, 4 in Leith, and 3 both in Edinburgh and in Paisley. The 9 deaths attributed to diarrhœa were fewer by 3 than the number returned in each of the two preceding weeks. The 8 fatal cases of whooping-cough showed a further decline from the numbers in the two previous weeks, but included 6 in Glasgow. Of the 6 deaths from scarlet fever, 2 occurred in Glasgow; and 3 of the 6 fatal cases of diphtheria were returned in Aberdeen. The 3 deaths referred to "fever" corresponded with the number in the previous week; 2 in Paisley were certified as cerebro-spinal fever, and a fatal case of enteric fever was recorded in Greenock. The deaths in the eight towns referred to diseases of the respiratory system, which had been 114, 107, and 100 in the three preceding weeks, were again 100 in the week under notice, and were 80 below the number in the corresponding week of last year. The causes of 16, or 2·9 per cent., of the deaths in the eight towns were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 578 births and 419 deaths were registered during the week ending March 19th. The mean annual rate of mortality in these towns, which had been equal to 22·8, 22·4, and 22·0 per 1000 in the three preceding weeks, further declined to 19·0 in the week under notice. During the first 11 weeks of the current quarter the annual death-rate in these Irish towns averaged 22·0 per 1000, whereas the mean rate during the same period did not exceed 15·1 in the 76 largest English towns and 17·6 in the eight principal Scotch towns. The annual death-rate for the week was equal to 18·4 in Dublin, 21·7 in Belfast, 19·9 in Cork, 9·6 in Londonderry, 19·1 in Limerick, and 13·6 in Waterford; the mean annual death-rate in the 16 smallest of the Irish towns was equal to 17·3 per 1000. The 419 deaths from all causes in the 22 town districts during the week showed a further decline of 63 from the numbers in the three preceding weeks, and included 34 which were referred to the principal epidemic diseases, against 30 and 28 in the two previous weeks; these 34 deaths were equal to an annual rate of 1·5 per 1000; in the 76 English towns the mean rate from the same diseases did not exceed 1·0 per 1000, while in the eight Scotch towns it was equal to 2·0. The 34 deaths from these diseases in the Irish towns included 21 from whooping-cough, 5 from measles, 4 from diarrhœa, 2 from scarlet fever, 1 from diphtheria, and 1 from enteric fever, but not one from small-pox. The fatal cases of whooping-cough, which had been 20 and 15 in the two preceding weeks, rose again to 21 in the week under notice, of which 12 occurred in Belfast, 3 in Drogheda, and 2 each in Lisburn and in Tralee. All the 5 fatal cases of measles and the 2 of scarlet fever were returned in Belfast; and 2 of the 4 deaths from diarrhœa, as well as the fatal case of enteric fever, occurred in Dublin. The deaths in the 22 town districts referred to pneumonia and other diseases of the respiratory system, which had been 146, 118, and 113 in the three preceding weeks, further declined to 104 in the week mentioned. The causes of 20, or 4·8 per cent., of the deaths registered in the Irish towns were not certified; in the 76 English towns the proportion of uncertified causes of death did not exceed 0·7 per cent., and in the eight principal Scotch towns 1·5 per cent.

In Dublin 242 births and 175 deaths were registered during the week ending March 26th. The annual rate of mortality in this city, which had steadily declined in the four preceding weeks from 28·0 to 18·4 per 1000, rose again to 22·6 in the week under notice. During the first 12 weeks of the current quarter the annual death-rate in the city averaged 24·1 per 1000, whereas the mean rate in London during the same period did not exceed 14·1 per 1000. The 175 deaths in Dublin last week included 6 which were referred to the principal epidemic diseases, against 9, 6, and 5 in the three preceding weeks. The annual rate from these epidemic diseases did not exceed 0·8 per 1000; the rate from the same diseases in London last week was equal to 1·0. The 6 deaths from these epidemic diseases in Dublin last week included 2 from whooping-cough, 2 from diarrhœa, and 1 each from enteric fever and from measles. Of the 175 deaths from all causes 64, or nearly 37 per cent., were recorded in public institutions. The causes of 3, or 1·7 per cent., of the deaths were not certified. In Belfast 208 births and 125 deaths were registered during the week under notice. The annual death-rate in this city, which had been equal to 21·6 and 21·7 in the two preceding weeks, declined to 16·7 in the week under notice, and was lower than in any previous week of this year. Of the 125 deaths from all causes, 14 resulted from the principal epidemic diseases, equal to an annual rate of 1·9 per 1000, and included 10 from whooping-cough, 3 from measles, and 1 from diarrhœa. The 125 deaths included 27 of infants under one year of age and 29 of persons aged upwards of 60 years; 3 resulted from violence, and 31, or nearly 25 per cent., of the deaths occurred in public institutions. All the causes of death registered in Belfast during the week were, with one exception, duly certified.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE following appointments are notified:—Fleet-Surgeon: C. S. Facey to the *President*, for eight months' civil hospital course. Civil Practitioner: E. A. King to be Surgeon and Agent at Burntisland.

ROYAL ARMY MEDICAL CORPS.

Lieutenant-Colonel F. H. M. Burton, at present in charge of the Military Hospital at Hounslow, has been selected to succeed Lieutenant-Colonel F. W. Caton-Jones in charge of the Military Hospital at Colchester. Lieutenant-Colonel B. T. McCreery, lately commanding the Station Hospital, Agra, has been temporarily placed on half-pay owing to ill-health. Lieutenant-Colonel H. A. Haines has arrived home from Fyzabad on completion of a tour of foreign service. Lieutenant-Colonel H. Carr, from Netley, Lieutenant-Colonel H. E. Cree, from Chatham, and Lieutenant-Colonel G. F. H. Marks, from Newcastle-on-Tyne, have embarked for India. Major W. T. Mould and Major A. W. Bewley have been selected for increased pay under Article 317 of the Royal Warrant. Major K. M. Cameron, Staff-Surgeon, Army Headquarters, Simla, on completion of his Indian tour of service, has been posted to Aldershot for duty. Major B. Forde, from Bloemfontein, has joined at Wynberg. Major J. Richie, from Woolwich, on arrival in India, has been posted to Multan. Major J. C. Morgan has been transferred from Cahir to Dublin. Major P. Collingwood, from Hong-Kong, has been appointed to Devonport. Major H. W. Grattan, lately on special duty in the Anti-typhoid Vaccine Department at the Royal Army Medical College, has arrived at Lucknow. Major E. T. Inkson, V.C., has been transferred from Bangalore to St. Thomas's Mount. Captain S. M. W. Meadows, on arrival from India, has been posted to the Eastern Command. Captain H. C. Hildreth, from Maymyo, has been posted to the Irish Command, and Captain M. D. Ahern, from Mandalay, has been posted to Ireland. Captain J. W. S. Seccombe has been transferred from Bangalore to Jullundur. Captain W. Davis, on exchange to India, has been appointed to the station hospital, Bareilly, for duty. Captain F. M. M. Ommanney has been transferred to the Home Establishment. Captain E. L. Moss, from Chaubattia, has joined at the station hospital, Bareilly, for duty. Captain A. E. Thorp, from Tidworth, has been appointed to Bulford Camp. Captain F. J. Palmer, specialist in operative surgery at Cork, on arrival in India, has been posted to Meerut. Lieutenant A. L. Foster, Lieutenant C. M. Rigby, Lieutenant T. S. Eves, and Lieutenant L. Murphy have embarked for a tour of service in India. Lieutenant E. D. Caddell has been transferred from Ambala to Subathu, and Lieutenant C. W. Bowle has been transferred from Dalhousie to Multan.

INDIAN MEDICAL SERVICE.

The official announcement of the promotion of the

Director-General of the Indian Medical Service, Lieutenant-Colonel Charles Pardey Lukis, to Surgeon-General (dated Jan. 1st) appears in the *London Gazette* of March 22nd.

The King has approved of the following appointments:—To be Lieutenants (dated July 31st, 1909): Charles Harold Smith, Alan MacDonald Dick, Thomas John Carey Evans, Robert Inglis Binning, Maurice James Holgate, Trevor Laurence Bomford, Graham Rigby Lynn, Louis Hope Lovat Mackenzie, John McDougall Eckstein, William Andrew Morton Jack, Alexander Charles Anderson, Duncan Gordon Cooper, David Arthur, William Leonard Forsyth, Keshav Sadishiv Thakur, Mohamed Abdur Rahman, Edward Humfrey Vere Hodge, Gerald Tyler Burke, Herbert Robert Burnett Gibson, and Mark Alleyne Nicholson.

The King has also approved of the following retirements:—Lieutenant-Colonel John Patrick Barry (since deceased), (dated Dec. 8th, 1909); Lieutenant-Colonel Richard Rose Weir (dated Feb. 21st, 1910).

Lieutenant-Colonel G. F. A. Harris, at present officiating as Inspector-General of Civil Hospitals in the United Provinces, has been appointed Inspector-General of Civil Hospitals in Bengal Presidency, with effect from March 1st. Lieutenant-Colonel C. C. Manifold, Bengal, is appointed to officiate as Inspector-General of Civil Hospitals in the United Provinces. Lieutenant-Colonel J. E. Fooks has had his leave extended until Dec. 5th next. Major C. A. Lane has arrived home on leave. Major R. D. Green, Civil Surgeon, Mymensingh, Eastern Bengal, has been granted combined leave for two years with effect from Feb. 7th. Major C. H. Bensley, officiating superintendent, Central Jail, Jubbulpore, has been granted 14 months' leave with effect from March 9th. Captain C. Godson has been appointed Civil Surgeon, Goalpara, Eastern Bengal. Captain Gillitt has been confirmed in his appointment as superintendent of the Central Jail at Buxar. Captain R. K. White has been posted for temporary duty at the disposal of the Chief Commissioner of the Central Provinces. Captain G. Hacheson, civil surgeon at Aligarh, Central Provinces, has been appointed to the visiting medical charge of the Bulandshahr District, vice Captain J. D. Graham. Captain A. D. Stewart has been given civil medical charge of Almora in addition to his military duties during the absence on leave of Captain G. T. Milchem. The services of Captain J. F. James have been placed temporarily at the disposal of the Government of Eastern Bengal and Assam. Captain A. T. Pridham has been appointed to the medical charge of the First Battalion, Eighth Gurkha Rifles, vice Captain C. D. Franklin. Captain A. W. Overbeck-Wright has been selected for temporary civil employment in the Jail Department at Dacca under the Government of Eastern Bengal and Assam.

TERRITORIAL FORCE.

Royal Field Artillery.

1st South Midland (Gloucestershire) Brigade: Surgeon-Captain W. J. Hill resigns his commission (dated Feb. 8th). 1st Welsh (Howitzer) Brigade: Surgeon-Captain David A. Davies to be Surgeon-Major (dated July 1st).

Royal Army Medical Corps.

3rd Lowland Field Ambulance: Lieutenant William K. Macdonald resigns his commission; J. Young to be Lieutenant (dated Feb. 8th).

1st Welsh Field Ambulance: Edmund Victor Connellan to be Lieutenant (dated Feb. 1st).

3rd Welsh Field Ambulance: Captain George A. Stephens to be Major (dated Sept. 2nd, 1908).

1st London (City of London) Field Ambulance: Duncan Campbell Lloyd Fitzwilliams to be Lieutenant (dated Jan. 3rd, 1910).

For attachment to Units other than Medical Units.—Ernest August Boxer to be Lieutenant (dated Nov. 24th); Frederick Reginald Sutton to be Lieutenant (dated Jan. 14th); Henry Halton (late Surgeon-Captain, 1st Lancashire Royal Engineers, Volunteers) to be Captain (dated Feb. 1st); and John Bart Rous to be Lieutenant (dated Feb. 8th).

Attached to Units other than Medical Units.—Captain John B. Jamieson to be Major (dated July 31st).

HONORARY SURGEONS TO THE VICEROY OF INDIA.

The following appointments have been made to the personal staff of His Excellency the Viceroy of India:—To be Honorary Surgeons (dated Jan. 1st, 1910): Surgeon-General A. T. Sloggett, C.M.G., R.A.M.C., Principal Medical Officer, 6th (Poona) Division; Colonel R. H. Forman, R.A.M.C., Principal Medical Officer, Bombay Brigade; Lieutenant-Colonel R. S. F. Henderson, R.A.M.C., Secretary to the Principal Medical Officer, His Majesty's Forces in India.

THE SPECIAL RESERVE.

We learn that, as the conditions of service become better known, the Special Reserve is becoming more popular. There are two categories in this force: (*a*) those who must be trained as soldiers and instructed in the technical methods of military service; and (*b*) those whose duties will be cognate to their occupations as civilians, and who therefore need little training. Reservists of the former class, Artillery, Infantry, and certain companies of Royal Engineers, must be trained in barracks and in the field, and when the force was instituted in December, 1907, instructions were issued for their organisation. In November, 1908, enlistment was commenced for the Army Service Corps and Royal Army Medical Corps in Class (*a*), and arrangements have been made for their organisation and training. Later in the same month provision was made for the enlistment of a large force of Army Service Corps and Royal Army Medical Corps in category (*b*) of the Special Reserve—that is, "serving and efficient members of the Territorial Force of the branch of the service they wish to join," who undertake the Special Reserve liability, qualified members of the St. John or St. Andrew Ambulance Associations being eligible for the Royal Army Medical Corps. They undertake the liability of being called out for permanent service at home or abroad when the Army Reserve is called out, and on mobilisation become in all respects soldiers of the Regular Army.

THE TERRITORIAL FORCE RESERVE.

A special Army Order has been issued approving of the creation of the Territorial Force Reserve. The privilege of joining the Territorial Force Reserve may be granted to individual officers, non-commissioned officers, and men by county associations acting on the recommendation of the commander of the unit to which it is proposed to attach the reservists. Officers are eligible to join the force who have completed four years' service as officers in any of the military forces of the Crown and do not belong to the General Reserve of Officers or to the Special Reserve.

FIRE AT HASLAR HOSPITAL.

A fire occurred at Haslar Hospital on March 23rd, which fortunately was unattended by personal injuries. The roof of the kitchen block was badly damaged, but the patients in the hospital were at no time in danger.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Dr. Georg Lockemann, *privat-docent* of Chemistry, has been granted the title of Professor.—*Clermont (Medical School):* Dr. Mornac has been appointed Professor of Internal Pathology in succession to Dr. Fouriaux.—*Düsseldorf (Academy of Practical Medicine):* Dr. Gustav Pfalz, Director of the Municipal Eye Clinic, has been appointed Professor of Ophthalmology.—*Göttingen:* Dr. Friedrich Port, assistant in the Medical Clinic, has been recognised as *privat-docent* of Medicine.—*Grenoble (Medical School):* Dr. Léger has been appointed Professor of Natural History in succession to Dr. Bordier, deceased.—*Königsberg:* Dr. Rehn, assistant in the University Surgical Clinic, has been recognised as *privat-docent* of Surgery.—*Leipsic:* Dr. Heinecke, *privat-docent* of Surgery, has been promoted to an Extraordinary Professorship.—*Munich:* Dr. Eugen v. Malaisé has been recognised as *privat-docent* of Neurology.—*Paris:* Dr. F. Vidal, *agrégé*, has been appointed Professor of Internal Pathology in succession to the late Dr. Brissaud. Dr. Ch. Achard, *agrégé*, has been appointed Professor of General Pathology and Therapeutics in succession to Dr. Bouchard.—*Vienna:* Dr Franz Erben of Prague has been recognised as *privat-docent* of Medicine.

Correspondence.

"Audi alteram partem."

THE BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH.

To the Editor of THE LANCET.

SIR,—All the chiefs of laboratories to whom I have spoken regret, as I do, that the Beit Fellows should be required to devote the whole of their time to their authorised research. The best men are holding demonstratorships or minor appointments, working to make their way on to hospital staffs. The Beit Fellowships under the present rules can be given to none of these men.

There are very few or no scientific posts waiting for men who agree to devote the whole of their time to these Fellowships. At the end of their three years the Fellows will be no better, but rather worse, placed than others for succeeding in their careers. An able man in a small portion of his time can effect infinitely more than a second-rate man in his whole time. I do not wish to say a word against any of the Fellows chosen in the first selection, but I think the electors cannot hope to find a succession of first-rate men to fill the 30 Fellowships under the present conditions. The heads of laboratories where research work of recognised value is done might have been trusted to disburse sums allotted them. This would, in my opinion, lead to far more fruitful results. They know the men who hold minor appointments, could choose the best and guarantee getting good work out of them.

I am, Sir, yours faithfully,

London, March 22nd, 1910. LEONARD HILL.

THE CONTROL OF SCARLET FEVER AND HOSPITALS FOR INFECTIOUS DISEASES.

To the Editor of THE LANCET.

SIR,—With reference to Dr. Crookshank's address published in your journal, may I invite his attention to the great difference existing in the promptitude with which cases of scarlet fever are notified and admitted into the hospitals of London and the provinces? In the latter, it is by no means unusual for cases to be detained until desquamation has so far advanced that the isolation hospital becomes a weak factor in limiting the dissemination of the disease through the district. If cases of this disease can be treated with impunity in the wards of general hospitals, I fail to see why they cannot be safely treated at the homes of the patients, and if so their classification as infectious maladies is surely a misnomer; I am nevertheless certain that we should object to have one of our own children suffering from an ordinary ailment brought into close proximity to a patient afflicted with scarlet fever.

I remember a case of diphtheria being treated in a block provided with only one ward kitchen, bath, and w.c., in which the unfortunate patient contracted enteric fever resulting in death, a calamity which could probably have been prevented had due precautionary measures been taken. However capable the matron may be she cannot be continually on duty in the wards day and night, and however careful the nurses may be, one must remember that they are only human and are therefore liable to error. I must admit that I do not attribute the infective activity of scarlet fever to cutaneous detritus as some authorities do. Moreover, a nurse who is constantly in a ward becomes a ready vehicle for contagion, whereas a medical man who seldom comes into immediate contact with the patients is not so likely to communicate the disease.

The temperature of a ward reserved for the treatment of diphtheria varies considerably from that of a ward set apart for scarlet fever, and there can be little doubt that overheated wards are often most injurious and encourage suppuration. Scarlet fever as a rule causes less constitutional disturbance than either diphtheria or enteric fever, and this seems to constitute an important indication for treatment in different wards. I cannot understand what economy would result from the nursing point of view, because a large ward with all the beds occupied would obviously necessitate an increased staff. I am of opinion that in many institutions the blocks are placed unnecessarily widely apart, and are on this account more difficult to work and supervise. The ambulance is, in my opinion, always open to suspicion, being so constructed as to render thorough disinfection impossible.

I have known of cases being sent to the hospital where the nurse and patient have been packed in with all the dirty bedding and rubbish from the house, with the tacit permission, if not by the express orders, of the sanitary authorities of the district. The procedure, of course, necessitated the continual opening and closing of the ambulance door. The laundry and disinfecting chamber constitute one room, the bedding being transferred from the disinfector to the laundry packed with soiled and infected linen; and yet this arrangement of buildings appears to merit the sanction of the Local Government Board.

A public conveyance driven by an ordinary cabman is frequently employed for the removal of infected bedding and clothes from the house to the disinfector, no precautions as the wearing of an overall or even the washing of his hands being taken by the man in charge of the vehicle before returning to his duties at the station or on the rank.

The majority of isolation hospitals become during epidemic periods overcrowded, and although built under Local Government Board supervision, and constructed for the accommodation of a limited number of beds, very little attention is paid to these restrictions, for four-bedded wards are sometimes used for ten or more patients, inviting all the evils which attend overcrowding. It would appear that the one absorbing motive of the medical officer of health is to secure the admission of cases into the local hospital regardless of the consequences, and this is especially the case if he does not happen to be the visiting physician to the hospital in question; the results of such a line of conduct are not only prejudicial to the nursing staff but detrimental to the welfare of the patients. The necessity of removing to the hospital cases, especially those of diphtheria and enteric fever, in their later stages does not appear to be sufficiently realised and enforced, the importance of isolation being much underrated, thus entailing risk to the patients and causing a rise in the death-rate. The responsibility for this does not rest so much with the medical attendant as with the medical officer of health, who is sometimes slow to adopt such measures as shall insure immediate removal on notification of the case.

The modern sanitary inspector is not unfrequently a young married man who, in order to minimise the risk of conveying infection to his family, entrusts the supervision and removal of patients' clothes, &c., to the hospital to one of his understudies, who in his turn perhaps hires a neighbour or odd man to assist him; whether any untoward results accrue from such a mode of procedure it is impossible to say, nevertheless it is not a fair policy to pursue in the interests of the public.

I am, Sir, yours faithfully,

EDWARD CARNELL, D.P.H., M.R.C.S. Eng.

March 28th, 1910.

THE INFECTIVENESS OF SCARLET FEVER.

To the Editor of THE LANCET.

SIR,—Only those who have seen several epidemics of scarlet fever can appreciate Professor Saundby's letter on the infectiveness of scarlet fever in your last issue. I believe it was Graves, the great Dublin physician, who first drew attention to the variations in virulence of different epidemics of scarlet fever, and I think he is quoted by Trousseau, who highly admired his work. There is no doubt about the truth of the observation, and it will easily be remembered by an occurrence at a provincial medical meeting some years ago now. A young practitioner thought he had discovered a specific (in some mercurial preparation) for all cases of this disease; but his treatment, apparently so convincing, never survived the criticism of an old doctor who was also present, and who had seen many epidemics, when he said: "There are some epidemics of scarlet fever which '*nowt*' will cure, and others which '*owt*' will cure, and our young friend has had to deal with the latter kind." Still, I am inclined to think that the serious results are less frequent, which may be attributed to the improved sanitation of houses, greater attention paid to the local treatment of the throat during the disease, and also the frequency of

operations for the relief or cure of naso-pharyngeal troubles in young children nowadays.

I am, Sir, yours faithfully,

Harrogate, March 26th, 1910. T. JOHNSTONE.

VARICOCELE AND THE PUBLIC SERVICES.

To the Editor of THE LANCET.

SIR,—Having initiated the discussion on this subject in your columns in 1905, I am gratified to see you return to the charge in a second leading article. So strongly do I feel this heartless, needless, and useless mutilation of youths who are keen to serve in the army that I consider it the bounden duty of the surgical profession to bring about a reform of the clause in the regulations recommending operation. I trust that all who may now discuss the subject will read carefully my letter of Sept. 23rd, 1905. One point bearing on the experience of other military surgeons than myself I then omitted to mention; it is this: I asked three of my colleagues employed in recruiting at St. George's Barracks whether they had ever treated any officer or soldier for varicocele during their service, and I received a prompt reply in the negative. Now, here were four of us army surgeons with an aggregate of 120 years' service in different parts of the world, and yet not one of us had ever seen any inefficiency from varicocele. Is it, then, that varicocele is more prevalent now than it was in years gone by? If so, why is it? What is the per mille, or per ten mille, rate of the condition treated in civil hospitals? When I invited naval surgeons (who reject for varicocele in any form outright) to give us their experience few, if any, responded. I know not why, for a military medical officer is not prohibited from expressing a professional opinion on a disputed question. If there is grave risk with one in a thousand of these operations the War Office is not justified in recommending an operation.

The whole business is, in my opinion, a phantasm which I trust you will succeed in laying, and I further trust that you may receive aid from the Director-General of the Army Medical Staff in doing so. It has often occurred to me that I should like now to carry out a thorough examination of all the candidates who have had operations performed to discover what have been the results. Those I examined years ago did not assure me of success.

I am, Sir, yours faithfully,

FRANK HOWARD,
Colonel (retired), Army Medical Staff.

Cromwell Mansions, S.W., March 26th, 1910.

To the Editor of THE LANCET.

SIR,—On reading the article in THE LANCET, "Varicocele and the Public Services," I was reminded of a conversation I had with the late Sir James Paget some years ago on the question of operation for varicocele, when he informed me that Nelaton had told him that he had never seen a case of varicocele amongst all the soldiers that had passed through his hands at the Hôtel des Invalides in Paris, which must have been a very considerable number. From this he argued that varicocele has a tendency to disappear in later life. Should this be borne out by other observers, is it not a strong argument in favour of not making the operation compulsory before entering the public services?

I am, Sir, yours faithfully,

York, March 26th, 1910. W. H. JALLAND.

ACCIDENT CLAIMS AS AFFECTING THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—I shall be obliged if you will allow me to place the following facts and opinions before your readers as I feel sure that you will agree with me that the subject is most important, and although my opinions may be distasteful to a very small minority I am certain that they will be endorsed by the great majority of the profession. Having during the last 15 years devoted my time almost entirely to the examination of cases of personal injury caused, or supposed to be caused, by accident, during which time I have examined over 11,000 cases, it will perhaps be granted that I must have had a large experience of the attitude shown by the profession when dealing with such cases.

Firstly, I wish to say that in that experience I have found medical men, with the exception of a very small percentage, absolutely straightforward and anxious to do their duty impartially, having due regard to the interests of their patients who were actually suffering from the effects of accident and whose claims were *bonâ fide*, and also having the same due regard to the interests of these claimed upon, if the disability was non-existent or greatly exaggerated. I am greatly pleased to bear witness to the upright attitude which has been in an enormous number of cases assumed by medical men who had immense inducements offered to them to diverge in some small degree from absolute honesty and truth. Many members of the profession will bear me out in voicing the difficulties continually encountered in dealing with claims.

1. Medical men in good practice have frequently rich patients—patients who are either valuable in themselves or by their connexions, patients whom they have always before thought to be eminently respectable and trustworthy, who, when face to face with an accident claim, seem to lose every particle of moral fibre. It may be that such a patient has an accident or an alleged accident, and some time after a doctor has been in attendance, during which time he has seen little or no objective sign of injury, it is suddenly sprung upon him that there is an accident claim pending, of which he has heard nothing and which at the last moment throws light on an obscure and bewildering case. A medical man called in to a patient is obliged to treat the aches and pains that are complained of, for if there are no objective signs he cannot discredit his patient and refuse to attend him; in fact, he would be very wrong in so doing, as there are many traumatisms of which there is no visible objective sign; but when he has treated his patient for some time with purely negative results as to the cause of the trouble complained of, what is he to do when suddenly asked to sign an accident claim certificate? He has to think, and the difficulties that confront him are immense, and if he is a struggling practitioner a source of insidious temptation.

2. Medical men associated with clubs are continually attacked by clever malingerers, so clever that they sometimes deceive the very elect; these make various statements when there is no sign of injury, and the difficulty arises as to how far the patient is to be believed, especially as if he is not believed, the medical man will be most likely threatened with the loss of the club, even if the claim is palpably a bogus one. Medical men are, however, in this matter not on a pinnacle by themselves, as I find that solicitors to societies and legal assistance clubs have sometimes the greatest pressure brought to bear on them with similar threats.

3. Medical men acting for a certain class of employer and the smaller fry of insurance offices are frequently in a very difficult position, as they are sent to examine workmen, being told beforehand to expect an absolute malingerer, for there is a certain order of lay mind to which the slightest particle of truth is unknown and to whom it is most distasteful. I say without fear that the profession has, under this stress, in the past nobly done its duty and has only been degraded by a few black sheep who must be present in every large flock.

I wish to call, however, the attention of the readers of THE LANCET to a development which has recently occurred, and which should, in my opinion, be nipped in the bud. Under the Workmen's Compensation Act, 1906, which largely extended the benefits of the previous Act, I regret to say that certain members of the profession, and some few even with high qualifications, are not acting up to the traditions of the profession and are bringing discredit on it, not only with employers and insurance offices, but with workmen and their organisations. As a Medical Referee appointed by the Home Secretary I have had many cases referred to me for report, in which the evidence shows that two medical men on each side have sworn diametrically opposite to one another on questions not of opinion but of perfectly apparent fact. I fully understand that medicine is not an exact science and there must be differences of opinion between the most high-minded men as to the condition or prognosis of certain cases, but I am reluctantly obliged to come to the conclusion that there are a few medical men now in London who will do everything possible for the person or persons by whom they

are employed; they make themselves partisans, and it is impossible for a partisan, however he may wish to be truthful, to be an absolutely impartial witness. I feel very strongly that a protest should be raised against partisanship in the witness-box, for the profession as a whole is being discredited by a fractional minority, who are, however, continually appearing in court as medical witnesses in accident cases.

Every member of the medical profession should understand fully that he is in a judicial position when asked to examine a case of personal injury alleged to be by accident, and therefore should be absolutely impartial. If acting for employers or insurance offices, the report should show the absolute facts, so that those interested may see exactly how they stand with regard to the claim. If acting for workmen, the workman should have absolute confidence that if there is a *bonâ-fide* disability he will be supported, but he should also know that in no case will he be supported when making a bogus or exaggerated claim.

I feel sure that the profession as a whole will be at one with me in this matter, and that even the fractional minority will agree that perpetually appearing in court on one side or the other, with palpable signs of partisanship, will not only weaken the profession but discount their own evidence in future cases, for county court judges are extremely acute men of the world. I am convinced that the great majority of workmen are honest in spite of great temptations, and it is in the interest of the mass of the workmen that it should be on the one side impossible for a *bonâ-fide* workman not to have his half wages under the Workmen's Compensation Act promptly paid to him, and on the other side that it should be equally impossible for a workman to succeed when making a fraudulent or exaggerated claim on an employer.

The Act as originally drafted made it possible for either employer or workman, without any expensive procedure, to ask for a reference to a Medical Referee appointed by the Home Secretary, and the Medical Referee would have before him the reports of the medical examiners employed on behalf of both employer and workman. Now that the judges are referring so many cases to Medical Referees after trial and the heavy expenses entailed by it, I think the matter should be reconsidered by all parties. On the one hand, employers are obliged to employ counsel and incur large costs, which it is impossible to recover even if they win. On the other hand, the present rule has been disastrous to many *bonâ-fide* workmen who have had serious or permanent disability, since it is impossible for them to obtain justice if they are not paid their half wages, or have them arbitrarily stopped before recovery has taken place, except by getting a solicitor to place their case before a judge, with counsel and medical witnesses, and probably having to face the wealth and experience of a great insurance company. In considering the balance of loss to either employers or workmen I think that workmen are the greater losers, and that it would be greatly in their interest if either employer or workman could ask for a reference instead of, as now, it being necessary for both to agree to a reference. In my experience I have seen many requests for a reference refused because one side or other thinks the side asking for a reference will win. As the law stands many workmen get nothing; others only get an award after great trouble and anxiety. Employers or insurance companies lose enormously, as the law costs incurred are frequently larger in amount than the claim.

Injured workmen frequently have not the wherewithal to pay for medical attendance; in other cases medical men find their treatment of a case handicapped by the want of proper nursing, food, or expensive appliances which are really necessary to effect a speedy recovery and a return to work. Patients, even when discharged from hospitals, often live at a distance and are unable to attend for the massage, physical exercise, or electrical treatment which it is impossible to obtain in the outlying suburbs. It may be quite an Utopian idea, but I am sure it would pay the insurance offices to look after their injured workmen and to combine to provide facilities in the suburbs for the proper treatment of the men, under the supervision of their ordinary medical attendants. That some scheme of this kind will have to be started sooner or later I am certain, unless the premium rates of insurance are raised and, in fact, made almost prohibitive. Many hundreds of claims in my own knowledge would have been cut down to half if it had been possible for the medical attendant to get his advice carried out.—I am, Sir, yours faithfully,

ALBERT BENTHALL, F.R.C.P. Edin.

South Hampstead, N.W., March 15th, 1910.

EXTRACTION OF CATARACT IN THE CAPSULE.

To the Editor of THE LANCET.

SIR,—I observe in your review of Ophthalmology for 1909 in THE LANCET of Dec. 25th last, that the writer thereof says that I have recently even ridiculed my opponents. The remarks I presume refer to 1909. The last paper I published was in THE LANCET of August 15th, 1908, and the only thing published since were my remarks in response to criticism at the Bombay Medical Congress of February, 1909. I think it would only be fair for your reviewer to quote or refer to what he terms "ridicule." I have little doubt that any fair-minded man will not include anything in the above-noted papers as "ridicule." In the matter of extraction of cataract in the capsule I stood out single-handed and alone against the world for years, and I have little doubt but that a generation hence I will have been considered to have been entertained to as much opposition, scientific and unscientific, as any man in modern times who has ventured to show that time-honoured doctrines were wrong, that the facts on which time-honoured theories appeared to be based did not exist. Your reviewer says it remains to be explained why I and the men whom I have trained get better results than our opponents. This is very easy to explain. Extraction of cataract in the capsule is probably the most highly technical operation in surgery. Those who do not get as good results as we do, do not know how to perform the operation, and their assistants probably do not know how to assist them, the part played by the assistant being almost as important as the part played by the operator.

I am, Sir, yours faithfully,

Amritsur, Punjab. HENRY SMITH, Major I.M.S.

*** There was no intention on our part to imply that Major Henry Smith had been discourteous to those who differ from him.—ED. L.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Industrial Employment of Married Women.

Dr. J. Robertson, the medical officer of health, has prepared an important report on the employment of married women and infantile mortality in Birmingham. He chose for thorough investigation two of the poorest wards of the city, covering an area of 289 acres and having an estimated population of 41,884 persons. The mean death-rate for the five years ending December, 1908, was 22·5 per 1000 and 20·3 per 1000 respectively. The infant mortality was 166 and 211 per 1000 births in 1909, while the infant mortality throughout the whole city was 135, a decrease of 17 per cent. as compared with the previous five years. The two wards chosen are occupied by works and small dwelling-houses. The population density was 152·7 and 162·1 persons per acre, the average for the city as a whole being 44·2. The houses are from 60 to 100 years old. In 1896 inquiry showed that 63 per cent. of the houses were of the back-to-back type. A considerable proportion are situated in common courtyards. The most important industry is metal working, and the number of chimneys emitting smoke is considerable, so that the people live under gloomy conditions, due to the soot and absence of trees and open spaces. In 1212 homes visited regularly during 1908 no fewer than 45 per cent. had total incomes from all sources of less than 20*s.* per week, while 20 per cent. had less than 10*s.* per week. Some idea of the extent of the employment of married women is given by the statement that of the women who bore children during 1908 no less than 54 per cent. went out to work. "I do not think," says Dr. Robertson, "it is far wrong to assert that in this area, having a population of over 40,000 persons, at least 50 per cent. of all the married women go to work before or after their infants are born. In 15 per cent. of the homes

visited the woman's husband was out of work at the time of the visit." In the two wards there were 1503 children born alive during 1908 and 39 stillbirths. The birth-rate was, therefore, a high one—viz., 35·8 per 1000. 1212 mothers were included in the inquiry; of these 601 were industrially employed during pregnancy—i.e., 49·6 per cent. Those employed after the birth of their children and while the child was still alive were 31·5 per cent. The mortality among the infants born in 1908 of all mothers employed either before or after childbirth was at the rate of 190 per 1000, while among those not industrially employed it was 207 per 1000. In this district, therefore, where half the mothers go to work, the mortality is rather less among the working mothers than among those who are not employed. Of 100 babies born prior to 1908 to those industrially employed 25 died during the first year, while for those not employed the figure was 20. The average age of the employed mothers was 28, of the unemployed 30. Of the 1212 mothers, 1157 were living with their husbands, 24 were living apart, 7 were widows, and 24 were single; 20 of the 24 women living apart from their husbands were employed, and 22 of the single women. In every instance inquiry was made as to why the mothers went to work and the replies were: sole or main source of income, 81; to supplement small income, 556; preference for industrial work, 20. The work done brought in on an average 8*s.* 5*d.* per week. The total earnings of the household apart from the mother's wages in the cases were as follows: in homes where the mother did not go to work, 23*s.* 1*d.*; in homes where the mother did go to work, 20*s.* 1*d.* No less than 140 of the women continued to work up to within a week of their confinement, while 205 stopped work over three months before. 57 women returned to work at or before four weeks after confinement. 75 per cent. of the mothers who were not employed and whose babies lived for 12 months fed their children with the breast, while only 27 per cent. of those employed did so. The babies so fed were heavier and better nourished than the others. Poverty, however, had a considerable influence on the infant, whether breast-fed or not, and Dr. Robertson again indicates the need for some institution capable of supplying food to hungry expectant mothers and to those who are nursing their children and are badly nourished. "These mothers live more exacting and self-denying lives than probably any other group in the community. What food comes into the house is given to the children or the husband, while they themselves go on from day to day in a state of semi-starvation." In Birmingham the type of industrial employment in vogue does not appreciably influence the health of the mother or her infant, when the standard of comparison is that of women in equally poor circumstances who are not employed industrially, but it is not maintained that such employment is free from all harmful influence. The mere fact that it prevents breast-feeding is, in Dr. Robertson's opinion, a reason for some State interference. In this Birmingham area, however, it seems to be a question whether the additional poverty which would be occasioned by preventing mothers from working, say, six months after a birth would not be the greater of two evils.

Hospital Saturday Fund.

The report for the year 1909 states that the total receipts amounted to £19,689. This was £943 below the total for the previous year. The number of contributing firms was 2171. £10,000 were voted last year for distribution among the medical institutions of the city. The total number of patients received at the three convalescent homes maintained by the fund was 2986. Since the first home was opened 18 years ago 345,666 patients have been received. The treatment of consumptive patients at special hospitals continues to be a very important part of the work, but the provision is altogether inadequate. Although a greater number of applications were received fewer patients were sent away, owing to the limited accommodation at Eversfield Hospital, St. Leonards, and the closing of the sanatorium at Weston-super-Mare to consumptives. The committee reports that the scheme for providing a consumptive sanatorium of its own as a memorial for the late Sir William Cook has made considerable progress. Already a site has been found not far from Birmingham which is considered in every way to be eligible and it can be procured on reasonable terms. A special fund for this purpose has been opened.

General Hospital.

At the annual meeting of the governors held recently an earnest appeal for subscriptions was made. The subscription list has been falling off for the last nine years, and now only amounts to £7163. This was attributed partly to the liberality with which in-patients were accepted without tickets, subscribers having stated that hospital tickets were not so much inquired for, and they proposed to reduce their subscriptions. In future tickets will be required to a larger extent in non-urgent cases. During last year £18,306 were spent upon in-patients, from whom no tickets were received. At the same time income from investments was also diminishing. The total expenditure for the year was £27,122, and there was an adverse balance of £11,427. The cost per occupied bed was £80 16*s.* A serious financial fact last year was that the accounts of the triennial musical festival, the proceeds of which go to the hospital, showed an adverse balance (apart from donations) of £1172. With the exception of 1888, when there was an adverse balance of £477, the working of the festival has hitherto resulted in a substantial surplus.

Ear and Throat Hospital.

The annual report states that the total ordinary income for the year was £2780 14*s.* 2*d.* and the ordinary expenditure £3174 14*s.* 1*d.*, leaving an adverse balance of £462 1*s.* 6*d.* The number of in-patients treated was 1686 and of out-patients 8267.

Lying-in Charity.

The annual report shows that the work has increased in all directions. In the district 1680 cases had been attended, the largest number since the foundation of the charity. 379 cases were admitted to hospital and 55 pupils were trained. No case was fatal from septic infection. The income was £3808 and expenditure exceeded this by £705.

Skin and Urinary Hospital.

There were 167 in-patients and 7071 new out-patients last year. 185 patients with 3612 attendances were treated in the X ray and Finsen light department. The total expenditure was £3017, an excess over income of £351, the accumulated deficiencies being £1895. An appeal was made for increased subscriptions and donations. £1000 are required to complete the electrical department and a further £1000 to establish a radium institute.

School Hygiene.

The report of the medical superintendent (Dr. G. A. Auden) on the medical examination of school children during last year shows that 26,484 children were examined, making a total of 36,678 since inspection began. The following defects were found:—Vision, 6/12 or less (all causes), 2816; squints, 700; external eye defects (blepharitis, corneal opacities, ulcers, &c.), 472; ears (defective hearing, otorrhœa, &c.), 1235; tonsils and adenoids, 1470; heart affections (congenital and acquired), 188; lungs (symptoms suspicious of phthisis, chronic bronchitis, &c.), 81; phthisis, 50; paralysis of muscles of limbs, 87; deformities other than paralyses (kyphosis, genu valgum, &c.), 176; chorea, 25; speech defects, 96; epilepsy, 42; skin, (*a*) ringworm, 421; (*b*) other skin affections, 259; hernia, 84. The number of parents present at the examinations showed a satisfactory increase. Dr. C. E. O'Connor presented a separate report on the inspection of children attending special schools. The number among the physically defective who were so through tuberculous disease was very large, being more than half.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

School Children's Diseases.

Mr. S. Hosegood, the medical officer of health to the Swinton and Pendlebury district council, calls attention to the increased prevalence of scarlet fever, especially in two of the wards. He attributes this increase in part to "parental indifference," which often leads to delay in dealing promptly with the first case occurring in a neighbourhood. In these wards an unnoticed case has frequently "been the focus for a more or less wide distribution of the disease." He gives expression to an opinion on the part played by schools in the spread of scarlet fever, which is not, at any rate, universally held. His observations as schools medical officer did not lead him to the conclusion that the spread of

disease was appreciably affected by school attendance, but was rather due to home influences and surroundings. He drew attention to a matter of great moment and one difficult to deal with—namely, to the absence of care on the part of parents in properly safeguarding the patient from contact with others. Without this care it was manifestly impossible for an efficient system of oversight and supervision to have adequate effect." There is evidently room here for much missionary work among our careless and ignorant population—ignorant, that is, not so much of the "three R's" as of many matters relating to the comfort and well-being of their families.

Gift of a Sanatorium to Bolton.

Mr. Thomas Wilkinson, J.P., recently gave a residence standing in its own grounds at Sharples, Bolton, to his native town. The value of the gift, including endowment, is estimated at about £100,000. Mr. Wilkinson was well known in his younger days as an athlete, and during his business career was a successful blockade runner at the time of the American war between North and South. Though now advanced in years and in somewhat feeble health he took part in the inauguration ceremony the other day. He is shortly to be made one of Bolton's freemen. He has also given an adjoining residence and the land about it, and as the whole of the buildings on these sites are admirably fitted for the purposes of a sanatorium, Bolton must be congratulated on the fact that its phthisical patients within the Bolton union area can now be treated in a thoroughly well-equipped sanatorium in pleasant surroundings.

Salford Hospital Dispute Ended.

It may be remembered that some time ago there was a dispute with the Salford guardians as to the medical superintendence of Hope Hospital, in which the British Medical Association disapproved of the arrangements, and the hospital was practically boycotted so far as applications for medical positions were concerned. As the result of negotiations, however, the medical administration is to be remodelled. The medical superintendent is to take complete control of the institution. The salary is to be £350 a year, increased by annual increments of £50 up to £500. There is a liberal allowance for housing.

Flannelette and Fireguards.

Flannelette continues to levy toll on the lives of the children. Last week a little girl named Almond, 4 years of age, was burnt to death in Hulme. This case was remarkable for a fraudulent attempt to show that the "accident" took place in spite of a fireguard being in front of the fire. The grandmother, it seems, after the occurrence borrowed a guard and tried persistently, as the coroner said, to pass off a neighbour's guard as the Almonds'. He said that she had tried deliberately to deceive the inspector who visited the house soon after the accident, and also his own officer a day later, and had tried to make a child tell a lie about it. He thought a prosecution ought to arise from the case. The guard was borrowed from a woman who had little children of her own, so another accident might have easily happened. No doubt the well-known views of the coroner had suggested the fraud. A case has just been described to me in which a little lad aged 8 years has died from his flannelette nightgown catching fire.

March 29th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Opening of the New Dental Hospital.

THE handsome and well-equipped building at the junction of Pembroke-place and Boundary-place, which has been erected during the last 14 months at a cost of £10,000, and is intended to supersede as a dental hospital the old institution in Mount Pleasant, was opened on March 19th by the Earl of Derby, in the presence of a large and representative gathering. Lord Derby arrived at the building at half-past four, and formally opened the hospital by the east, or main, door, being presented with a handsome gold key as a souvenir of the occasion. Lord Derby and the other visitors then inspected the building, a notable feature of which are spacious and exceptionally well-lighted apartments, and afterwards the entire company assembled in the large upper room, Lord Derby taking the chair. Amongst those present were the Lord Mayor and the Lady Mayoress, Sir Charles and Lady Petrie, Mr. L. S. Cohen (the chairman of the hospital committee) and Mrs. Cohen, Professor A. M. Paterson (honorary treasurer), Professor L. R. Wilberforce, Vice-Chancellor A. W. W. Dale, and a large number of members of the medical and dental professions. The Lord Mayor, in opening the proceedings, remarked that at the present time, thanks to the progress of medical science, people had made up their minds that the care of teeth was of great importance for the health of the body, and dental hospitals were now recognised as an absolute necessity for the welfare of the community. There was one feature of the hospital which was to be commended; he referred to the arrangement whereby those who used the hospital were able to contribute towards its support according to their means. He hoped this system would long continue. Mr. Cohen proposed a vote of thanks to Lord Derby for having opened the hospital. Referring to the building fund, Mr. Cohen thanked in particular Mrs. and Miss Holt, Sir William Hartley, and Sir John Brunner for their handsome subscriptions, as also the dental staff, who had subscribed £1000 for the equipment of the hospital. They required £10,000, and now they were only £1500 short. The committee had bought the land from the corporation, who had commuted a ground rent of £900. A large portion of the land had not yet been built upon, and it was proposed to utilise it as a lawn tennis ground or as a croquet lawn in connexion with the University. Liverpool had reason to be proud of its new dental hospital, which was accessible from all parts of the city. Professor Paterson moved a vote of thanks to the subscribers to the building fund, and said that it was the best and cheapest dental hospital ever built. Mr. Cohen had spared no effort to make the hospital a success, and he was the first to come forward with a promise of 10 per cent. (£1000) on the amount required. He also paid a tribute to the great assistance the committee had received from Mr. W. H. Gilmour (the warden of the hospital). Mr. Gilmour seconded the vote of thanks to the subscribers in an appropriate speech. Mr. Mansell (the chairman of the staff) presented to Mr. Cohen a replica of the key given to Lord Derby, and expressed the hope that he would long be spared to continue his services as chairman of the hospital. Vice-Chancellor Dale proposed a vote of thanks to the Lord Mayor and Lady Mayoress, and eulogised the beneficent work of the hospital.

Hospital Sunday Fund.

The collections on behalf of the Hospital Sunday Fund for the year 1910 to date amount to £5493 4*s.* 5*d.* The corresponding collections for 1909 amounted to £5526 18*s.* 6*d.*, whilst the corresponding collections for 1906 amounted to £5567 15*s.* 9*d.* These amounts do not include donations. A further list will appear later.

Another Death from Anthrax in Liverpool.

The Liverpool coroner held an inquiry on March 21st touching the death of a woman, aged 41 years, who was employed by a firm of sack merchants as a bag-mender. On March 16th she was engaged mending some sacks which had contained bones. A small boil was observed on her neck, and she became ill. On the following day she was taken to the David Lewis Northern Hospital, and thence to Fazakerley Hospital, where she died the same day from anthrax. The bones were said to have come from Alexandria with a mixed cargo of hides, skins, and wool. Upon hearing the medical evidence the jury returned a verdict of "Death from anthrax."

March 25th.

LEEDS.

(FROM OUR OWN CORRESPONDENT.)

Installation of the Chancellor of the University.

THE Court of the University, on the nomination of the Council, has invited His Grace the Duke of Devonshire to follow the late Marquis of Ripon as Chancellor. The acceptance of the position by the Duke has caused the liveliest satisfaction in University circles, for everyone who remembers the association with the Yorkshire College of the late Lord Frederick Cavendish will regard as singularly appropriate the selection of a member of the same distinguished

family as head of the University. The installation will take place on June 11th.

Appointment of Lecturers in Practical Surgery and in Operative Surgery.

Consequent on the appointment of Mr. R. Lawford Knaggs to the professorship of surgery, a vacancy has been created in the lectureship on practical surgery. Mr. Walter Thompson has been appointed by the Council to this position. Mr. Thompson was the lecturer on operative surgery, and in this capacity he is succeeded by Mr. J. F. Dobson.

Closing of the Winter Term.

The second term at the medical school came to an end on March 23rd, and the third term will commence on April 25th. As on former occasions, dissection may be carried on during the vacation after Easter Tuesday.

Annual Meeting of the Leeds General Infirmary.

There was a large attendance at the annual meeting of the friends of the General Infirmary, which was held on March 16th. On these occasions the treasurer, Mr. Charles Lupton, is in the habit of taking the annual report and balance-sheets as read and making some careful comments on them. Mr. Lupton's comprehensive grasp of all that pertains to hospital finance and management tends to make all that he says worthy of careful note. Dealing with the work of the infirmary Mr. Lupton said that the increasing demand on the accommodation seemed to make the institution get smaller and smaller year by year, and he contemplated the necessity of an early appeal to the public for an increase in accommodation. As usual, the work had increased, for the number of in-patients was 220 over that of the former year and amounted to 7357, while the new out-patients numbered 48,351, an increase of about 6000. Though the infirmary had paid its way and invested some funds during the past year, Mr. Lupton showed that this excess of income over expenditure was due to causes which were accidental and which could not be relied upon to occur again. Of £44,000 received £19,000 represented legacies and special donations, and, indeed, the only source of income which has not lessened was that of the Workpeople's Hospital Fund, which in spite of bad trade had given the same handsome subscription of £5250 as in former years. On the other hand, the ordinary subscription list was back to where it was in 1892, and the congregational subscriptions to where they were in 1870. The total expenditure of the institution had increased by £1300. Among immediate requirements was the opening of a new ward with 28 beds, and the provision of two additional operating theatres. A sum of £7000 would be required to meet the cost of structural alterations, and from £3500 to £4000 to meet the increased cost of maintenance. Under ordinary circumstances the income was some £6000 less than the expenditure, and that deficiency, though happily more than met this year, had to be covered from the precarious source of special legacies and donations. Mr. Lupton also pointed out that the infirmary was opened in 1868, and it was, like all buildings 40 years old, requiring the annual expenditure of large sums in maintenance and repairs.

March 29th.

WALES.

(FROM OUR OWN CORRESPONDENTS.)

The Extension of Cardiff.

To those acquainted with the rapid increase during the past 20 years, not only of Cardiff but also of the districts immediately adjoining, the enlargement of the boundaries of the city would appear to be but a natural development and quite in accordance with the spirit of the times. A few years ago an attempt was made to include the adjoining urban district of Penarth within the city area, but the proposal was unsuccessful owing to the opposition of the Penarth residents, who feared that the rates of the urban district would be raised to those which prevail in Cardiff. A committee of the corporation is now considering the details of a scheme, to be embodied in a Parliamentary Bill, for the inclusion in Cardiff city of portions of the rural district of Llandaff and Dinas Powis. The present proposals are that Llandaff, Whitchurch, and Llanishen should be included in the enlarged area. The newly erected asylum, or as it is officially styled, Mental Hospital, which has been erected by the Cardiff corporation, is situated in Whitchurch, and the Cardiff waterworks, including a reservoir of 300,000,000 gallons capacity, which served the town before the Brecknockshire Beacons supply was obtained, are in Llanishen. The tendency of the present day is to gather adjoining populous districts under one administrative control, and with the examples of the federated pottery towns and the proposed creation of a Greater Birmingham it is a little surprising that the Cardiff people have not considered the more ambitious scheme of making the area of the Cardiff union co-terminous with that of the city. The union had a population in 1891 of 173,000 and in 1901 of 229,000, and includes, in addition to Cardiff, the rural district of Llandaff and Dinas Powis and the urban districts of Barry and Penarth. The aggregate population at the present time is well over 300,000. As already stated, some of the Cardiff enterprises are situated in the Llandaff and Dinas Powis rural district, and the Cardiff water is supplied to Penarth, while negotiations are proceeding for its supply to Barry. The large outfall sewer which is now being constructed for the discharge of the Cardiff sewage into the Bristol Channel beyond Lavernock point passes through the Penarth urban district and could be utilised to receive the Penarth drainage to the advantage of that town, the sewage of which is now discharged into the Channel near to Penarth Head and in the proximity of the promenade. For Customs purposes Cardiff, Penarth, and Barry are one port, and the Cardiff port sanitary authority includes within its area of administration Cardiff and Penarth, Barry being a separate port sanitary authority. There thus appear to be many reasons why the creation of a Greater Cardiff should be possible and to the advantage of the districts concerned.

Pauperism in Wales.

At the last meeting of the Hay board of guardians Mr. Hugh Williams, the Poor-law inspector of the Local Government Board for North and South Wales and Monmouthshire, referred to the recently issued Order of the Board relating to the boarding out (within unions) of children. He stated that of the 2500 children in his district 900 were in the several workhouses and belonged chiefly to people who had been described as the "ins and outs." Nearly 1000 were boarded out with foster parents and were for the most part well cared for, some 500 were in certified schools, while about 250 were in service under the supervision of the guardians, who saw that they were paid and properly treated. There were in the workhouses of Wales and Monmouthshire about 10,500 inmates, but barely 100 of this number were capable of doing a good day's work. It is disheartening to learn from Mr. Williams that the rate of pauperism is higher in Wales than in other parts of Great Britain, notwithstanding the fact that it includes large and prosperous industrial centres. He expressed the opinion that the increase in pauperism was a problem which boards of guardians must set themselves to solve, and urged that, although it appeared cheaper for the moment to give out-relief, the offer of the workhouse should be made more frequently, such an offer being no hardship to questionable people while it acted beneficially upon the community as a whole.

Obituary: David Davies, F.R.C.S. Eng., of Aberdare.

Through the death on March 17th of Mr. David Davies, F.R.C.S. Eng., L.R.C.P. Edin., L.S.A., the medical profession of the South Wales colliery districts has lost its oldest member. Mr. Davies was born in 1821, and after serving an apprenticeship with the late Dr. Redwood of Rhymney studied at Guy's Hospital. In 1843 he took the M.R.C.S. and two years later settled in Aberdare where he has lived ever since, retiring from practice only three years ago. Aberdare, which has now a population approaching 50,000, was inhabited 65 years ago by about 7000 persons, and its colliery developments have been very great. In 1863 Mr. Davies was appointed medical officer of health of Aberdare, and held the position for 44 years, during which period sewerage and water-supply schemes have been carried out and the general sanitary administration of the town has been developed. As surgeon to the collieries which sprang up during his lifetime, Mr. Davies had considerable local reputation, and he lived long enough to see the enormous improvements which were made

in surgical practice owing to the introduction of aseptic methods. He was on the commission of the peace for Glamorgan, and took a considerable amount of interest in the public life of Aberdare. He joined the Volunteers in 1859 and retained his commission as honorary surgeon until the formation of the Territorial Force.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

The Edinburgh Corporation and Consumption.

TWO recommendations of the public health committee of Edinburgh were brought before a meeting of the corporation of the city on March 22nd. One recommendation was that a contribution of £450 per annum should be made to the Dispensary of the Royal Victoria Hospital for Consumption, which should be used for extending the work of the Dispensary, while the information which had been accumulated by the Dispensary officials should be placed at the disposal of the medical officer of health. The second recommendation was that a grant of £500 per annum should be made to the hospital, in return for which ten beds should be set apart in the hospital for early cases of phthisis to be selected by the medical officer of health. There was a good deal of discussion on these recommendations and there was a considerable minority opposed to the scheme, including the late convener of the committee, Dr. Cullen. The recommendations were, however, carried by 28 votes to 12.

New Librarian for the University of Edinburgh.

At a meeting of the Edinburgh University Court Mr. Frank C. Nicholson, M.A., was appointed chief librarian to the University. Mr. Nicholson was a distinguished student at Christ Church, Cambridge, taking honours in the classical tripos, and special distinction in German in the mediæval and modern languages tripos. He studied in Germany. He held the post of assistant librarian to the University of Aberdeen, and in 1903 was appointed acting librarian to the Royal College of Physicians of Edinburgh. He is well qualified for the post, and many of the readers of THE LANCET will be interested to know that he is a son of the late Professor Alleyn Nicholson of the University of Aberdeen.

Proposed Hospital at Insch.

The late Miss Margaret Smith, Alvah Cottage, Insch, by her will leaves £50 towards a fund for the erection of a hospital at Insch for the relief of sick and ailing persons. This fund is to go along with a legacy of £50 bequeathed by her brother, the late Mr. James Smith of Insch. Miss Smith directs that the sum of £50 shall be retained by her trustees, and the interest thereof accumulated by them so long as they can legally do so, until sufficient funds are obtained to erect a hospital as mentioned.

Sidlaw Sanatorium.

The governors of Dundee Royal Infirmary at their last meeting gave formal approval of the draft agreement providing for the transference of the Sidlaw Sanatorium. The chairman expressed the gratitude of the governors to Mr. Caird for his donations. He then outlined the course of negotiations between parties and remarked that an agreement was come to, approved by Mr. Caird, whereby not only were 20 beds set aside for tuberculous children and seven endowed beds retained for adult phthisical patients, irrespective of sex, but accommodation was also reserved for other sufferers from pulmonary complaints, and thus the original purpose of the institution seemed reasonably fulfilled.

Medical Inspection of Schools in Aberdeen and the North.

The Secondary Education Committee for Aberdeenshire has now received replies from most of the boards of the county on its proposed scheme for medical inspection. In all 86 boards have decided to adopt the committee's scheme, four have as yet intimated no decision, and one, that of the Rayne board, has signified disapproval. By the committee's scheme it is proposed to appoint a medical officer at a salary of £300 (exclusive of travelling expenses), which is to rise by £25 per annum to £400. It is also proposed to appoint an assistant or assistants, the salary proposed being £200, to rise annually by £25 to £300.—A meeting of Caithness Secondary Education Committee was held in Wick recently. The committee had before it a report from the bursary committee as to the medical inspection of school children, in which it was estimated that the cost of the scheme for the county would be £500, one-half of which had to be paid by the county committee. It was decided that, first, by recommending the scheme of grants to school boards and reducing the grants by 20 per cent. a saving of £240 could be made; and, second, by dropping out of future budgets of the committee the sum set aside to make grants to teachers attending vacation classes a further saving of £60 would be effected, and this would meet the cost to the extent payable by the committee for the medical inspection. It was considered that these were the only two modes of carrying out the medical inspection: by having inspection for the county alone or by coöperating with Sutherland. The committee appointed a subcommittee of three to meet with the Sutherland education committee on the subject.

Presentation Portrait to Professor A. Ogston.

The committee in charge of the presentation portrait of Professor Alexander Ogston requests intending contributors to forward their subscriptions at an early date to the honorary secretary, Dr. J. Mackenzie Booth, 1, Carden-place, Aberdeen.

Obituary.

Mr. Alexander Forbes Chisholm Clark, M.B., C.M. Aberd., died at his residence in Dundee on March 15th from an attack of pleurisy. Dr. Clark was 44 years of age, a son of Mr. William Clark, and a brother of Dr. W. H. Clark, Woodside, Aberdeen. After a brilliant student career he graduated M.B., C.M., Marischal College, before he was 21 years old. He practised at New Deer and Old Deer, and was afterwards assistant in the Melrose District Asylum for two or three years. He then took up practice in Dundee, where he has been for 20 years. He was of a gentle, retiring disposition, and was held in high esteem. He is survived by a widow and two young daughters.—The death took place on March 26th at his residence, Parkburn House, Kilsyth, of Mr. John Fraser, M.D. Edin., L.R.C.S. Edin., who was a native of the parish of Dores, near Inverness. He graduated M.D. and L.R.C.S. in 1852. Three years after graduating he settled in Kilsyth, where he continued to practise until about a month before his death. From the time of the adoption of the Police Act in Kilsyth until his death he acted as burgh medical officer; he was one of the medical officers to the parish council, and held several appointments in connexion with friendly societies and works in the district. Dr. Fraser built up a very large practice in Kilsyth, and for many years required the services of two or three assistants.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Convalescent Home, Stillorgan: Annual Meeting of Governors and Subscribers.

AT the recent annual general meeting of the governors and subscribers of the Convalescent Home, Stillorgan, the report of the committee of management stated that 1145 patients had been admitted to the institution during the year 1909. In the course of his address to the meeting the chairman stated that during the South African war several soldiers had been admitted to the institution, and with highly beneficial results. In 1862 the number of patients admitted was 57 only; in 1882 it was 792; and in 1908 it had increased to 1262. Mr. A. J. Horne, President of the Royal College of Physicians of Ireland, in proposing the adoption of the report, pointed out to the audience that the home existed for the purpose of supplying fresh air, rest, and wholesome food for the sick poor of Dublin and the neighbouring counties. The cost per diem of each inmate was 10¾*d.*

Kingstown and the Health Resorts and Watering-places Act.

As I have on a former occasion pointed out, there were several Irish mineral and thermal springs which over a century and half ago quite rivalled in the public eye the fame and fashion of Bath, and stood far higher in medical and scientific estimation than did those of Buxton

and Harrogate at that time. They gradually lost their celebrity and popularity when the "union" came to centralise Irish fashion in London. Now that the Health Resorts and Watering-places Act of last year has given a new chance to our Irish resorts, the corresponding public bodies have special opportunities, and some of these are already paying active attention to the provisions of Mr. MacVeagh's useful measure. It was proposed at a recent meeting of the Kingstown urban council that a rate should be struck for the purposes mentioned in the Act, and a levy of ½*d.* in the £ was unanimously agreed to. But the council rejected a recommendation that a sum of £100 should be contributed to the funds of the central council formed by a number of persons specially interested in the promotion of the objects of the Act. The majority preferred to formulate a general scheme and to procure afterwards the financial assistance of those councils that adopt the Act in carrying it out; the main argument in favour of this procedure is that it will prevent overlapping and consequent waste of resources.

Ulster Hospital for Children and Women.

At the annual meeting of the friends of this charity it was reported that 227 children, 74 women (gynæcological), and 6 women (maternity) were admitted into the wards, while in the extern department there were 2260 children (including 466 eye cases) and 612 gynæcological and 269 maternity cases. Financially, the income for the year was £1062 17*s.* 2*d.*, to which, when the sum of £151 3*s.* 6*d.*, carried forward as a balance from the previous year, was added, left a net income of £1224 0*s.* 8*d.* The expenditure was £1218 9*s.*, which left a balance of £5 11*s.* 8*d.* in hand. Towards the building fund for the new hospital £7550 have been subscribed.

Royal Victoria Hospital, Belfast.

The annual meeting of the governors of this hospital was held recently. The report stated that during 1909 there were 3068 cases admitted into the wards, which with 220 remaining from the previous year, makes a total of 3288 intern patients. Of these new cases, 1713 were surgical and 1365 were medical. In the extern department there were 29,850 new cases. The total number of new cases treated in the hospital (intern and extern) amounted to 32,891. Financially, the year started with a debit balance of £768 6*s.* 3*d.*, and closed with a balance of about £1000 more on the same side (£1787 10*s.* 8*d.*). The receipts from all sources amounted to £15,454 17*s.* 5*d.*, and the disbursements of all kinds came to £16,474 1*s.* 10*d.* Special attention was drawn to the want of more electrical equipment, the accommodation for which is at present too small, and also for a proper equipment for the vaccine-therapy work.

Seizure and Destruction of Lard.

A firm in Belfast was summoned by the Belfast corporation for having in their possession on Feb. 16th, 1910, for the purposes of trade, 74 barrels of lard to which a false trade description—to wit, "pure Continental lard"—was applied contrary to statute. Further, the firm was summoned on the ground that the lard was unwholesome. After hearing a great deal of evidence the magistrates decided that the article contained in the 74 barrels was unwholesome, and condemned it to be destroyed under the supervision of the medical officer of health. Further, they imposed a penalty of £20 on the other charge of applying a false trade description to the lard, and ordered the lard to be forfeited and destroyed.

March 29th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Meeting of the International Dental Federation.

THE annual meeting of the International Dental Federation was held at the Sorbonne, Paris, on March 25th. Professor Dastre, of the University of Paris, representing the Minister of Public Instruction, welcomed the members. The President, Mr. W. B. Paterson of London, delivered an address, in which the Federation's work, as the permanent bureau of international dental congresses, was outlined for the ensuing year. Among the various subjects indicated the following were set down for consideration: Public dental hygiene in connexion with Poor-law schools and the naval and military services, and pedagogics in the medical and dental schools from an international point of view. At the conclusion of the President's address speeches were made by the representatives of the various national dental societies and associations constituting the federation—viz., M. Francis Jean and Dr. C. Godon of Paris; Professor Jessen, Strassburg; Mr. J. H. Mummery, London; Dr. Williams, Adelaide, Australia; Dr. Florestan Aguilar, Madrid; M. Rosenthal, Brussels; Professor Kirk, Pennsylvania University; Ch. Vincenzo Guérini, Naples; Dr. Lenhardtsen, Stockholm; M. van der Hoeven, The Hague; and others. The appointment of committees on dental education and public dental hygiene was then made. During the meeting, which occupied two days, the award of the Miller International Memorial Prize was made for "eminent services to dentistry" to Dr. G. V. Black, of Chicago, U.S.A. In the absence of Dr. Schaeffer-Stuckert, of Frankfort, the report of the secretary-general was read by Dr. W. Guy, dean of the Edinburgh Dental School. The report, amongst other matters, referred to the question of the admission of dentists to International Medical Congresses, on which an official communication had been addressed to the Permanent Committee of the International Medical Congress now in session at The Hague as follows:—

The Executive Council of the International Dental Federation has the honour to ask the Permanent Committee of the International Medical Congress to take into serious consideration its opinion on the question of the admittance of dentists to, or their exclusion from, future International Medical Congresses.

If there is to be a Section of Stomatology or Dentistry, then, as the work of such a section will be to invite, to collate, and to discuss every advance in dental science and art, and, as the great proportion of such advance is made by dentists, it appears obvious that its work will necessarily be incomplete and its survey greatly limited, if it does not include dentists in its membership. The Council of the International Dental Federation would therefore urge upon the bureau of the International Medical Congress the wisdom and propriety of admitting dentists to a Dental Stomatological Section, if it is desired that the work of such a section be authoritative and complete.

The Council of the International Dental Federation further submits the opinion that if the work of a so-called Stomatological Section is to be limited to the discussion of such matters only as are of medical and surgical interest and importance, as distinguished from dental, then it appears to it that a Stomatological Section is hardly necessary, as these matters can be better and more fully discussed in the Sections of Medicine and Surgery.

In short, it considers that scientifically there is no justification for the existence of a Stomatological Section which excludes dentists, and hopes therefore that your committee will decide to strengthen and complete the Stomatological Section by admitting dentists.

On March 27th the ceremony of the unveiling of a memorial statue to Horace Wells, dentist, Hartford, Connecticut, discoverer of surgical anæsthesia by nitrous oxide gas in 1844, took place in the Place États Unis. The Minister of Public Works presided and was supported by several departmental heads of the municipality, Professor Dastre and other members of the Medical Faculty of Paris, the president of the British Dental Association, and members of the International Dental Federation and the American Dental Society of Europe. Various eulogistic speeches were delivered.

The Floods and the Health of Paris.

The normal average of deaths of the city of Paris during the first eight weeks of the year is 8850. In 1909 the total deaths during the same period amounted to 8919, and this year during the same period, when the flood was at its height, the deaths amounted to 7713. As regards typhoid fever, from Feb. 20th to 26th, 1910, there were 31 cases and 3 deaths among the 2,700,000 inhabitants. In the corresponding week of the year 1909 there were 36 cases and 6 deaths. Surely these figures are the most striking of all.

The International Congress of Physiotherapy.

This Congress was opened by the President of the Republic in the large amphitheatre of the Sorbonne on March 29th in the presence of a large official gathering. The Congress and associated exhibition will remain open until the end of the week.

(FROM OUR OWN CORRESPONDENT.)

Hospitals and Well-to-do Patients.

THE "Consiglio degli Ordini dei Sanitari" (a body which has not a little in common with both the British Medical Association and the General Medical Council) has, after much animated discussion, decided on taking action in abatement of an abuse of long standing in hospital administration—to wit, the admission of well-to-do patients into the

wards originally destined for the poor or the less-favoured portion of the community. Representatives of the principal medical schools and seats of hospitals throughout the kingdom were present, Dr. Arturo Guzzoni, professor of obstetrics in the University of Messina, presiding. Evidence was brought before the council of the abuse in question—amounting in many cases to this: that not only are the ailing poor often "crowded out" by admissions well able to call in a duly qualified practitioner for treatment under their own roof, but that the interlopers even in hospital are able, thanks to their ample means, to pay for extra care on the part of the nursing *personnel*, so that the other inmates of the ward, unequal to the disbursement of "tips," have often to put up with perfunctory attendance and to suffer in consequence. Now, however, in the interests of the public and in those of the profession, we are likely to see the end of this abuse, the council having unanimously come to the following resolution:—

The "Consiglio Federale," in its endeavour to carry out the just conception of the "hospitalisation" of the greater number of patients and to protect the interests of the poor, resolves that the wards of public hospitals should no longer be open to patients whose private means are known to be ample, but that these latter should be accommodated, with a special *personnel* in attendance, in wards set apart for them exclusively, admission to which will be conceded on terms of payment proportioned to the clinical attention required, it being left free to the consultant or practitioner and the patient to settle between them the remuneration due.

The late Miss Isla Stewart.

May Florence be allowed to lay its little *immortelle* on the grave of this true "Sister of Mercy"? When just three years ago, at the instance of the governing body of St. Bartholomew's, she came to the City of Flowers for a brief respite from work she received not only from the profession but from the well-informed lay public, Italian as well as British, the welcome due to her honourable record in hospital administration and philanthropic endeavour. All who had the opportunity of meeting her were speedily impressed by her force of character, her centripetal insight into detail and her appreciation of the dominating factor, her catholic sympathies, her *sagacité de cœur*. No experience, particularly in her own *métier*, was thrown away upon her, and the hints and suggestions she made in her survey of the local hospitals were treasured all the more that there was some hope of her early return to the city when she might have witnessed how loyally and intelligently her advice had been utilised. But *dis aliter visum*. Florence was destined never to see her again, and now, to the regrets which follow her, can but add the expression of its own:—

Va-te-ne in pace, alma santa e bella.

March 26th.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

The New Hungarian Pharmacopœia.

THE new Pharmacopœia Hungarica will come into force on July 1st. It differs greatly from the preceding one, inasmuch as it comprises several new features with regard to the manufacture of drugs and the dispensing of prescriptions. A chapter has been added on the sterilisation of hypodermic solutions. The officially assigned maximum doses of certain drugs, especially of those which may act as poisons, are altered in several instances, generally in the direction of diminution. For instance, in the last Pharmacopœia the maximum dose of atropine was 0·002 gramme, and that of extract of belladonna was 0·05 gramme; whilst in the new one these doses are respectively 0·001 and 0·03 gramme. "Poisons" are denoted by the mark +, and "very active poisons" by the mark ++; these drugs are supplied by the pharmacists only on the production of a medical prescription. In the last Pharmacopœia 120 substances were marked + and 21 were marked ++, but in the new one 137 substances are marked + and 25 are marked ++. The substances marked + include bromine salts, antipyrine and its combinations, formaldehyde, guaiacolum carbonicum, kalium sulphoguaiacolicum, liquor hydrogenii hyperoxydati concentratissimus, and santonine. In order to protect Hungarian pharmaceutical chemists from the German and Austrian competition the new Pharmacopœia names certain proprietary preparations, when it is desired to include them, according to their chemical composition, without reference to their commercial designations. For instance, protargol is described not by that name but as argentum proteinicum; dionin as æthylmorphinum hydrochloricum; and bromidia as mistura chloralo-bromata. Of course, when it happens that the trade name has no scientific equivalent, it remains unchanged in the Pharmacopœia. New drugs to the number of 124 have been added, and 120 old ones have been omitted. Among the latter is agaricus chirurgicus, which has been used only as a hæmostatic after the application of leeches. Aqua calcis saccharata has also been omitted because it did not fulfil the expectation that it would act as an antidote against poisoning by carbolic acid. Hydrargyrum iodatum flavum has been omitted because nobody prescribes it. Guaiacolum is omitted, being replaced by the better preparation guaiacolum carbonicum, which is now made official. Petroleum rectificatum and cognac are also omitted because they can be obtained in every grocer's shop. Sal thermarum Carolinarum (Carlsbad salt) is omitted because the artificial Carlsbad salt is just as good and much cheaper. Stibium sulphuratum rubrum is obsolete and therefore omitted. Unguentum sabadillæ is omitted as it is of doubtful efficacy, and on account of its violent local action it may even prove dangerous. Vinum colchici is omitted because the Pharmacological Congress held in Brussels did not sanction the preparation of powerful drugs in the form of medicated wines. Vinum condurango is omitted because the fluid extract of condurango is much more efficacious. Vinum malagense is omitted because it is for the most part an artificial wine, and our Hungarian product, the Tokajer wine, is substituted for it. Acetate of zinc and valerianate of zinc are omitted as being obsolete. A few remarks may here be made regarding some of the new additions to the official materia medica. Acidum acetylosalicylatum: This substance, commercially known as aspirin, is indispensable at present. Æther ad narcosim: Our former official ether was not suitable for use as a general anæsthetic and foreign ether had therefore to be imported; the æther ad narcosim, if prepared according to the instructions of the new Pharmacopœia, will be very suitable for narcosis, and the expensive foreign ether will be replaced by a trustworthy home product. Æthylmorphinum hydrochloricum: This substance, known commercially as dionin, is extensively used in ophthalmology. Amylenum hydratum: This substance is a good hypnotic, especially in cases of alcoholic psychoses. Argentum proteinicum: This substance, commercially known as protargol, is indispensable in urological practice. Benzinum: This substance is indispensable in surgical practice. Chloroformum ad narcosim: It was necessary to bring into the Pharmacopœia a preparation which shall be purer than the one used at present and able to compete with the chloroform of foreign makers such as Pictet or Macfarlane. Chloroformum ad usum externum: As the anæsthetic chloroform is expensive a cheaper preparation for external use had to be introduced. Fluid extract of secale cornutum: Until now German preparations, such as Denzel's and Bombellon's, have been in use; the fluid extract made according to the instructions of the Hungarian Pharmacopœia is efficacious and not liable to decomposition. Liquor ferri albuminati and liquor ferri albuminati saccharati: There are so many untrustworthy commercial preparations of iron that it seemed necessary to describe good preparations which have a definite composition, containing 0·4 per cent. of iron. Pastilli nitroglycerini: Clinicians have requested that an official preparation of nitro-glycerine shall be kept in the pharmacies. Syrupus kalii sulphoguaiacolici: This substance is very much the same as sirolin prepared by Hoffman La Roche Co. at Basle in Switzerland; it has the recommendations of cheapness and good quality, as well as of being a home product. The other recent additions to the Hungarian Pharmacopœia need no special explanation.

March 26th.

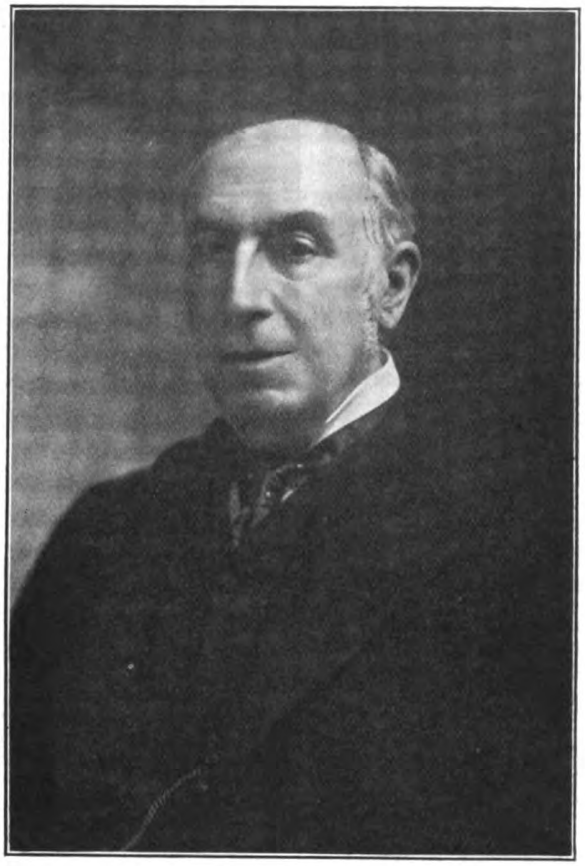
DEATH OF A SUPER-CENTENARIAN.—Mr. Jeremiah Martin Simmonds, who on March 21st reached the remarkable age of 102, died two days later at his residence in Brighton, where he had lived for nearly 80 years. He was the oldest inhabitant of Brighton. Simmonds was a gardener and had been three times married. There are now two centenarians living in Brighton; they are Mrs. Norman and Mrs. Sinden. They occupy beds side by side in the workhouse infirmary.

Obituary.

WALTER BUTLER CHEADLE, M.A., M.D. CANTAB., F.R.C.P. LOND., F.R.G.S.,

CONSULTING PHYSICIAN TO ST. MARY'S HOSPITAL AND TO THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

IN the death of Dr. Cheadle the medical profession has sustained a heavy loss, and there will be many who, hearing the sad news, will feel that they have parted with an old and valued friend. Dr. Cheadle passed away on Good Friday, March 25th, after a long and distressing illness, which was borne with steadfastness and heroic fortitude, and throughout which he showed those qualities that had gained for him the true admiration of his friends.



Walter Butler Cheadle was a Yorkshireman, being the son of the Rev. James Cheadle, Vicar of Bingley. He was born in October, 1836, and so has died in his seventy-fifth year. He was educated at Bingley Grammar School and went up to Cambridge as a scholar of Gonville and Caius College in 1855. A good athlete, and fond of cricket and all field sports, he excelled as an oarsman, and had it not been for a family bereavement would have rowed in the University boat-race in 1859. When talking over old times he often used to remark laughingly that it was fortunate for him that he had been compelled to resign his seat in the boat as he could not swim a stroke, and it was during that year's memorable boat-race that the Cambridge boat capsized. Leaving Cambridge, he pursued his medical studies at St. George's Hospital and obtained his M.B. degree in 1861. Between this date and 1865, when he proceeded to his doctorate, he had an experience such as falls to few medical men, an experience which marked him out as an explorer of great endurance and resource. On June 19th, 1862, he embarked in the s.s. *Anglo-Saxon* with the late Viscount Milton to explore a route across the continent of North America to British Columbia through British territory by one of the northerly passes in the Rocky Mountains. During the hazardous journey many adventures and great dangers were encountered in safety. These were recorded in a most fascinating book, "The North-West Passage by Land," written conjointly by the leader of the expedition and Dr. Cheadle. This book speedily ran through eight editions, and its interest was much enhanced by a ninth edition in 1901, which contains a postscript by Dr. Cheadle, touching upon the further explorations that had been made in the country, and the subsequent fate of the prominent men who had accompanied Viscount Milton and himself on their historic journey. Dr. Cheadle was always a modest and most retiring man, and it was a rare pleasure to induce him to show the numerous interesting relics in his possession. The travellers returned in the *China* on March 5th, 1864, to find themselves famous, but Dr. Cheadle laid aside his geographical laurels to settle down once more to hard medical study for his M.D. degree. In 1866 he was appointed assistant physician to St. Mary's Hospital upon the retirement of Sir James Alderson, and for nearly forty years he was in active service there. In these days it seems strange to record that he was dermatologist to the hospital until the election of Sir (then MR.) Malcolm Morris. In 1869 he was appointed dean, and took an active part in founding entrance scholarships and advancing the status of the school. The same year saw his appointment as assistant physician to the Hospital for Sick Children, Great Ormond-street, where he achieved a far extended reputation for the treatment of children's diseases. During his 23 years of service at this hospital he used his influence repeatedly to add to the number of subscribers, and endowed the "Cheadle" cot in memory of his first wife. Dr. Cheadle was in active hospital life at a time when the "lady doctor" was greatly exercising the medical world, and in the teeth of strenuous opposition he upheld her cause, and gave lectures at the Medical School for Women at a time when it required some moral courage to do so. He took a practical interest in the training and position of nurses, and among other services readily granted to them he gave at one time a series of lectures on hygiene to the Nursing Association in Bloomsbury-square. Always public-spirited, he supported the athletic clubs attached to the medical school of St. Mary's Hospital, presented portraits of some of the most distinguished of its teachers and students to the library, and in 1898, shortly before his retirement from the staff, he gave £600 to endow a Cheadle prize and medal to be awarded to students of St. Mary's for proficiency in clinical medicine. His connexion with the Royal College of Physicians of London was a long one. He was elected a Fellow in 1870, examiner from 1885–88, Councillor and Censor in 1892, 1893, and 1898, and Lumleian lecturer in 1900.

When we recall the immense experience that Dr. Cheadle possessed we can readily understand the value of his writings, which were essentially terse and practical. In 1877 he made his first observations upon a mysterious disease in childhood characterised by pain and tenderness, hæmorrhages, and swelling of the gums, an account of which was afterwards published in THE LANCET; now it is generally known as infantile scurvy, the name he gave to this disease. In 1888 he delivered the classical Harveian lectures upon Rheumatism in Childhood. In 1889 his equally well-known book upon the artificial feeding of infants appeared. In 1896, on the last occasion of a meeting of the British Medical Association in London, he introduced the discussion on Acute Rheumatism in the Medical Section. In 1900 he devoted the Lumleian lectures to "Some Cirrhoses of the Liver," and lastly must be mentioned his "Occasional Lectures on the Practice of Medicine," a volume full of practical hints from a mature judgment.

As a teacher Dr. Cheadle was at his best when at the bedside with senior students and qualified men, and what especially impressed his pupils was his eminently sagacious conduct of his cases. He never fussed, but he did much in little details for his patients' comfort. For many years Dr. Cheadle had a large and responsible practice and inspired the greatest confidence in his patients. Circumstances rather than desire drove him largely into children's practice, for he himself had an expressed antipathy to the designation of specialist. His manner with children was particularly charming and they rewarded him with their complete confidence and affection. As a physician he possessed great insight, a finely balanced judgment, and much therapeutic skill. He was a man of imposing presence, and dignified, courteous, and reserved in manner. Absolutely straightforward and possessed of great kindliness of heart, his was a personality which must have remained in the memory of the most thoughtless of his students, for there was no finer representative of British medicine. Many heavy sorrows fell upon him in later years and as a result he withdrew more and more into himself and was seldom to be seen in public. He was twice married, first to Anne, second daughter of Mr. W. Murgatroyd of Bingley, secondly to Miss Emily Mansel Mansel, daughter of Mr. Robert Mansel of Rothbury, both of whom predeceased him. He leaves four sons by his first wife.

Dr. Cheadle's body was buried at Eastbourne on March 30th, in the presence of a number of his old friends.

Dr. D. B. Lees sends us the following tribute to his former colleague both at St. Mary's and at the Great Ormond-street Hospitals:—"Dr. Cheadle's contributions to the advancement of medical knowledge were mainly the results of his careful work and observation in a region then only partially explored and full of opportunity for the investigator—the study of the diseases of infancy and of early life made possible by the establishment of the Hospital for Sick Children, Great Ormond-street. In this field Jenner, Dickinson, Gee, and others had already worked, but valuable discoveries still were possible. Dr. Cheadle paid special attention to the question of the proper feeding of infants and to the morbid conditions produced by errors in this matter. He laid down the principles which should regulate the feeding of infants, and the practical application of these principles, in his lectures on the Artificial Feeding of Infants delivered at St. Mary's Hospital. To him is due also the earliest recognition of the occurrence of scurvy in young children as a clinical fact. His Harveian lectures on the various phases of rheumatism in early life were full of instructive facts and observations, and showed that the current conception of acute and subacute rheumatism as a form of arthritis occurring in adults, with occasional cardiac and other 'complications,' must be modified by the inclusion of very different symptoms and combinations of symptoms produced in early life. The reception of this truth was for a time only partial, and the 'peculiarities' of the disease in childhood were appended to descriptions drawn from adult patients. Even now it is not sufficiently realised that the

WALTER BUTLER CHEADLE, M.D., F.R.C.P., F.R.G.S.

true type of the disease is that which occurs in children, and that it is the adult that is 'peculiar.' When this view is universally accepted, it will be seen how valuable was the elucidation of the facts supplied by Dr. Cheadle. Dr. Cheadle did effective work in many capacities at St. Mary's Hospital—as lecturer on pharmacology, on pathology, on medicine, and on clinical medicine, and for four years as dean of the medical school. His memory will long be cherished as an upright, conscientious, practical and careful physician, whom everyone respected. The gold medal in clinical medicine which he founded has already produced much good work, and is the most valued distinction open to students of St. Mary's Hospital. Dr. Cheadle was of quiet and retiring disposition, but all who knew him were impressed by his sincerity, his straightforwardness, his unselfishness, and his kindness of heart. Of such a man and of such true original work his colleagues cannot but be proud."

Another former colleague writes:—"Dr. Cheadle's kindly nature and his genial manner endeared him to all who knew him, and to none more than to his colleagues at St. Mary's Hospital, with whom he at all times worked with unvarying loyalty and with never-flagging interest in the welfare of hospital and school. And none of those who knew him well could but be impressed with his high sense of honour and his devotion to duty. He regarded the regular and punctual performance of his hospital work as a call upon him never to be postponed or delayed; he never grudged giving ample time to it, and there was scarcely a day in which he did not visit his wards. And his patients one and all appreciated the time and attention he gave to them. He always brought to bear on them the same mental activity and clinical acumen that rendered his opinion second to that of no one. He was not given to theorise or to overstate what he found or inferred. What he did not understand he frankly stated, but he was very accurate and singularly correct in his diagnosis and in his interpretation of symptoms. Dr. Cheadle was too conscientious to rely always upon his own judgment alone; when doubt entered his mind he frequently invited the opinion of his colleagues, even of his juniors. Throughout his career he always kept himself well informed upon, and ready to adopt, new methods of treatment, or to avail himself of the use of newly introduced drugs. And he was most exact and discriminating in his directions for treatment and dieting of the individual patient. His teaching at the bedside was never formal, but it was always practical and given in a quiet, attractive manner which was especially grateful to those sensitive students who, under-estimating their own powers, shrink from the ordeal of too searching an examination. To the preparation of his short courses of lectures, given usually in the theatre, Dr. Cheadle always gave great pains and illustrated them with diagrams, experiments, specimens, and records of cases which made them invaluable. The large numbers who attended them showed how they were appreciated, and there must be many generations of students who find their practical value in their daily work, especially in the care and treatment of young infants. Dr. Cheadle was a loyal colleague and an unfailing friend, unassuming, unostentatious, generous, and honourable, with a high standard of duty and of conduct which he never failed himself to observe, and he leaves behind him affectionate memories among all who knew him at St. Mary's."

CANADA.

(FROM OUR OWN CORRESPONDENTS.)

The Conservation of Natural Wealth.

FOLLOWING in the footsteps of the United States and of some European countries, Canada intends to inaugurate measures at once to conserve her natural wealth. President Taft, speaking on the subject recently in the United States, expressed himself thus: "The problem is how to save and how to utilise, how to conserve and still to develop, for no sane person can contend that it is for the common good that nature's blessings are only for unborn generations." The Canadian Commission for conserving the natural resources of the country and for taking measures for the maintenance of public health met in the Carnegie Library, Ottawa, when it was decided that precautions should be taken to conserve the forests of Canada, and especially of British Columbia, and in every way to safeguard the national natural resources, under which heading are included fur-bearing animals and all game, as well as timber and water-sources. Dr. P. H. Bryce, chief medical inspector of the Department of the Interior, is one of the Commissioners.

Bill to Abolish Compulsory Vaccination in Ontario.

A Bill has been introduced into the Ontario Legislature to abolish compulsory vaccination. Municipal councils in Ontario now have the right to pass by-laws to enforce vaccination and not infrequently employ this power. The Bill is for the purpose of repealing the present Act and of leaving it to each person to decide for himself or herself whether he or she should be vaccinated.

High Rate of Infant Mortality in Ontario.

The death-rate of infants under one year of age in the Province of Ontario is very high. The annual report by the Registrar-General of births, marriages, and deaths in the Province of Ontario for the year ending Dec. 31st, 1907, shows that in Toronto during that year there were 6680 births, of which number no less than 1313 infants died before they reached the age of one year, giving a death-rate of 196 per 1000 births. In Ontario out of a total of 53,584 births in 1907, there occurred 8041 deaths of infants under one year of age, giving a death-rate of 150 per 1000 births. The corresponding rates for the same period in Chicago were 134 per 1000 births and in New York 171 per 1000 births. At a recent meeting of the Academy of Medicine of Toronto a resolution was moved in the Section of State Medicine by Dr. Goodchild requesting the Academy to appoint a special committee to consider and report upon the question of infant mortality. This resolution was carried and a committee has been appointed.

New Medical Building of McGill University.

Some of the buildings of McGill University were destroyed by fire about three years ago, and among these the building of the Medical Faculty. All have been rebuilt, with the exception of the medical building, which is in course of construction and which will be completed, it is expected, in the early part of the summer. The new medical building, which although lacking a wing is finished so far as the exterior is concerned, is a solid, somewhat picturesque stone edifice which faces and is in convenient proximity to the Royal Victoria Hospital. It is well arranged internally, containing large and airy lecture-rooms, library, and numerous class-rooms. The wing which will complete the structure is to be commenced at once. It is worthy of note that among the medical students of McGill University no fewer than 55 are English.

Toronto General Hospital.

Work will commence early this spring upon the erection of the new Toronto General Hospital, the ground having been partially prepared last fall. Recently the hospital has been in receipt of another handsome donation of $250,000 from Mr. J. C. Eaton, of Toronto. This is to be devoted to the surgical side of the hospital and is to commemorate the donor's father, Mr. Timothy Eaton. The site of the new hospital cost $608,615, and it is proposed to expend some $2,000,000 on the construction. Toronto is to give an additional $200,000. The plan of the hospital will be as follows: A main building fronting on College-street; an emergency building, the gift of private benefactors; the out-patient department, the gift of Mr. Cawthra Mulock, Toronto; building for private and semi-private patients; nurses' home with accommodation for 174 nurses; Burnside building, for accommodation of obstetrics; servants' quarters; central power-house; pathological building to be built and maintained by the University of Toronto, which is additional to a cash grant of $600,000. The public wards of the hospital will contain 449 beds; the private and "semi-private" wards of the hospital will be in a separate building with capacity for 98 beds. For the eye, ear, nose, and throat department there will be 36 beds; gynæcology, 39 beds; general surgery, 145 beds; medicine, 150 beds; emergency, 9 beds; obstetrics, 36 beds. This provides for 124 more beds in the public wards than in the present building and 22 more than in the present private wards.

The Milk-Supply of Ontario.

Last spring the Ontario Government appointed a Milk Commission to inquire into the milk-supply of the province and

to look into the milk-supply problem generally. At the present session of the Legislature, the commission has reported through its chairman, Dr. A. R. Pyne of Toronto. The report recommends that the general principles governing the production, care, and distribution of milk for human consumption should be fixed by the legislature; that in the interests of the public health and common decency more attention should be paid to the cleanliness of cow stables and of the healthfulness of cattle, and to this end the consuming municipalities should be empowered to make inspections at the source of supply and be urged to appoint veterinaries to act in conjunction with the local medical officer of health; that in cities of over 50,000 population no milk should be sold in shops except in bottles or other sealed packages; that cans, bottles, and other utensils used in handling milk should be used for no other purpose, and should be promptly rinsed by the consumer on being emptied. Toronto was found to have the worst milk-supply in Ontario and Ottawa the best. Toronto consumes 2336 eight-gallon cans of milk a day, which comes from about 900 farms within a radius not exceeding 40 miles. The report finds that "certified" milk is the ideal, but can probably never be attained except for the sick and infants; that pasteurised milk is an expedient but a good one. On the question of pasteurisation, the report makes special mention of the work being done in the Hospital for Sick Children, Toronto, where, through the generosity of Mr. John Ross Robertson, a pasteurisation plant was installed last summer. Here some 1200 children are fed upon pasteurised milk in the wards annually, and some 12,000 as out-patients. As the mortality of the hospital is about 1 in 3, it is being carefully watched as to what effect it will have in reducing that mortality.

March 21st.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—H. R. L. Allott (Section I.), Sheffield; S. Danziger (Sections I. and II.), Manchester; J. A. Laughton (Section I.), Charing Cross Hospital; C. P. A. de L. Pereira (Section II.), Birmingham; L. M. Potter (Section I.), Geneva and Royal Free Hospital; C. Pyper (Sections I. and II.), Leyden; E. Renouf (Sections I. and II.), Royal Free Hospital; R. Rowlands (Section II.), Glasgow and Westminster Hospital; and G. F. Wilson (Section II.), London Hospital.

Medicine.—K. Baylis (Sections I. and II.), Royal Free Hospital; M. Graves (Section I.), London Hospital; A. W. Hansell (Sections I. and II.), Leeds; A. Y. Massey (Section II.), Toronto and University College Hospital; C. P. A. de L. Pereira (Sections I. and II.), Birmingham; and G. F. Wilson (Section II.), London Hospital.

Forensic Medicine.—A. W. Hansell, Leeds.

Midwifery.—H. R. L. Allott, Sheffield; E. G. Brisco-Owen, Cardiff and Royal Free Hospital; and L. M. Potter, Geneva and Royal Free Hospital.

The diploma of the Society was granted to the following candidates, entitling them to practise medicine, surgery, and midwifery:—S. Danziger, A. W. Hansell, C. P. A. de L. Pereira, and G. F. Wilson.

VICTORIA UNIVERSITY OF MANCHESTER.—At examinations held in March the following candidates were successful:—

FINAL M.B. AND CH.B.

G. M. Benton, C. G. Brentnall, R. A. Jackson, N. T. K. Jordan (Second-class Honours), Cedric Pimblett, Alexander Porter, W. W. Stacey, and A. C. Turner.

Obstetrics.—Estelle I. E. Atkinson and T. E. Dickenson.

Medicine and Surgery.—G. T. Cregan.

Medicine.—W. B. Walmsley and William Wright.

Forensic Medicine and Toxicology.—A. E. Ainscow, Rupert Briercliffe, Caleb Davies, H. A. Dunkerley, E. R. Eatock, Gertrude H. Geiler, P. S. Green, Harold Heathcote, R. C. Hutchinson, W. H. Parkinson, W. Hoyle Parkinson, Alexander Reid, J. B. Scott, W. A. Sneath, J. P. Stallard, James Walker, and Charlotte E. Warner.

SECOND M.B. AND CH.B.

Walter Barnes, W. L. Cox, W. C. C. Easton, R. B. Gorst, G. B. Horrocks, A. H. Macklin, and Harold Sheldon.

Physiology.—L. B. Baird, L. S. Daly, and Roderick MacGill.

THIRD M.B. AND CH.B.

General Pathology and Morbid Anatomy.—O. R. Allison, Benjamin Herald, A. H. Holmes (distinction), L. W. Howlett, W. H. Laslett, Newton Matthews, Frank Oppenheimer, Samuel Rawlinson, G. E. Sawdon, R. P. Stewart, and Gordon Whitehead.

THIRD B.D.S. EXAMINATION.

A. C. W. Hutchinson.

Physiology, Dental Anatomy, and Histology.—T. A. B. Corless.

DIPLOMA IN DENTISTRY (THIRD EXAMINATION).

L. W. Ward.

Physiology.—Wilfrid Jackson.

Dental Anatomy and Histology.—D. M. Lawrie.

DIPLOMA IN DENTISTRY (FINAL EXAMINATION).

W. G. Dykes and C. E. McNabb.

Dental Surgery and Dental Prosthetics.—F. B. Preston.

DIPLOMA IN PUBLIC HEALTH.

John Allen, William Bradley, David Fenton, W. J. Hoyten, R. A Needham, and R. T. Turner.

DIPLOMA IN VETERINARY STATE MEDICINE.

W. W. Henderson, John Holroyd, A. B. Mattinson, and Brennan De Vine.

UNIVERSITY OF LEEDS.—At the second examination for the degrees of M.B., Ch.B. (Anatomy and Physiology), the following candidates were successful:—

H. Angel, J. H. Blackburn, J. Ferguson, G. W. L. Kirk, F. H. Kitson, G. P. Mellis, J. C. Metcalfe, M. Peto, S. Samuel, and H. W. Symons.

The following appointments to external examinerships were made in the Faculty of Medicine:—Anatomy: E. Fawcett, M.D., C.M. Physiology: W. D. Halliburton, M.D., F.R.C.P. Materia Medica and Pharmacy, Pharmacology and Therapeutics: A. R. Cushny, C.M., M.D. Pathology and Bacteriology: G. Sims Woodhead, M.A., M.D. Forensic Medicine: F. J. Smith, M.D., F.R.C.P. Public Health: H. T. Bulstrode, M.D. Medicine and Mental Diseases: L. E. Shaw, M.D., F.R.C.P. Surgery: L. A. Dunn, M.B., F.R.C.S. Obstetrics and Gynæcology: J. S. Fairburn, M.B., F.R.C.S.

ASSOCIATION OF MEDICAL OFFICERS OF HEALTH.—A council meeting of this association was held on March 24th at the Holborn Restaurant, with Dr. F. G. Crookshank in the chair. Mr. D. A. Belilios, the honorary secretary, reported that at the last meeting of the Home Counties Branch of the Society of Medical Officers of Health, Dr. Crookshank (chairman of the association) had been nominated for the presidency of the society in succession to Dr. Cooper Pattin. It was unanimously agreed that steps be at once taken to support Dr. Crookshank at the election, which is to take place at 1, Upper Montague-street, Russell-square, on April 8th, at 5 P.M.

THE HOME TRAINING OF GIRLS.—The education committee of Brighton has approved of a scheme of an experimental character for the establishment of a school of home training for girls. A systematic course of instruction in domestic subjects is to be provided for girls immediately after leaving the elementary schools. The "municipal school for home training," as it is to be called, is to be open to 80 girls per annum; while selected groups of girls definitely intending to enter domestic service will be drafted into a model home for short periods of special practice in actual housework. The teachers are to be resident in the home, which will be managed by a committee of ladies.

MUNICIPAL MILK DEPÔTS.—The Lambeth borough council on March 17th showed itself more concerned about public health than its own public health committee. The committee presented a report by Dr. J. Priestley, the medical officer of health, containing some striking statistics of the saving of infant life effected by the municipal milk depôt, and followed it with a recommendation that the depôt be discontinued. At the council no one, not even the chairman of the committee, defended the proposal, and by a considerable majority it was decided to continue the depôt. Dr. Priestley stated that during four years 672,032 bottles of "humanised" milk had been supplied to 849 infants and children. The death-rate amongst those who were fed on the milk for six months or more was only at the rate of 22·7 per 1000, and the average on all the depôt-fed children only 69·5 per 1000, against a general infantile death-rate in the borough varying in the different wards from 110·9 to 199·7 per 1000. Making allowance for the comparatively small numbers dealt with, it was evident that there had been a large saving of life amongst the depôt-fed children and infants, and, in addition, the depôt had had a considerable educational influence. The council had allowed £200 yearly to meet the cost, and this sum had been somewhat exceeded in 1908 and 1909. The depôt could supply 400 to 500 children per day without proportionately greater expense. The cost compared favourably with that of the depôts at Woolwich and Battersea. The

public health committee brought forward its recommendation on the following grounds: that municipal milk depôts had not yet been legalised; that the systematic visiting of new-born infants since the Notification of Births Act came into operation made the depôts unnecessary; and that the number of applicants for the milk had not shown a progressive increase.

THE GRESHAM LECTURES.—Four lectures on elementary domestic hygiene will be delivered at the City of London School, Victoria Embankment, E.C., by Dr. F. M. Sandwith, the Gresham Professor of Physic, on Tuesday, Wednesday, Thursday, and Friday, beginning with April 5th. The lectures, which begin at 6 P.M. and are free to the public, embrace the subjects of elementary physiology, air and water, and the sanitary requirements of a home.

SAILORS' HOSPITAL AT VENICE.—Mr. de Zuccato, H.M. Consul at Venice, in his annual report just issued through the British Foreign Office, writes:—"The cosmopolitan hospital continues to give the utmost satisfaction to all classes of seafaring people, as this institution has been placed in a condition of high efficiency, in accordance with the best British methods, chiefly through the indefatigable efforts of Lady Layard, the honorary secretary. The hospital deserves to be visited and the committee to be encouraged in the charitable work they are carrying on. It is situate at Rio della Croce at the Giudecca, but there are steamers going there from St. Mark's every 20 minutes. Any small contributions English tourists might kindly give towards the comfort of those fellow-countrymen who are detained there by sickness would be gratefully received and acknowledged by Lady Layard, Ca' Capello, San Polo; or the Rev. A. L. Price, D.D., English Chaplain, Casa Hruska, Aocademia, Venice."

THE ROYAL SANITARY INSTITUTE.—A sessional meeting of the institute will be held at 90, Buckingham Palace-road, London, at 5 P.M. on April 6th, when a paper will be read on "Sanitary Aspects of Floods and Measures to be taken to Prevent Epidemics arising therefrom" by Dr. A. J. Martin, Inspecteur Général des Services d'Hygiène de la Ville de Paris. Mr. A. Wynter Blyth will preside. On April 8th there will be a provincial sessional meeting at Plymouth when Colonel J. Lane Notter will preside. The proceedings will commence at 7.30 P.M. in the Guildhall by discussions on the "Removal of Town Filth" and "The Relative Value of Disinfectants in the Control of Diseases." The first will be opened by Mr. J. Paton, the borough engineer and surveyor of Plymouth, and the second by Mr. O. Hall, medical officer of health of Devonport. On the following day (Saturday) visits will be made to Messrs. James and Rosewell's Lead Works, and a luncheon will be held at the Globe Restaurant. Application for tickets and for further particulars should be made to Mr. F. M. Williams, Municipal Buildings, Plymouth, who is acting as local honorary secretary of the meeting; or to Mr. E. White Wallis, the secretary of the Royal Sanitary Institute, Buckingham Palace-road, London, S.W.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Easter Holidays.

ONLY three Parliamentary days have been devoted to the Easter holidays by the House of Commons this year, whilst the House of Lords is taking a week. These periods are much shorter than Parliament usually allows itself at this time of the year, but of course the whole Parliamentary situation is dominated by an unusual set of political events. The next few weeks, during which the question of the limitation of the veto of the House of Lords will be discussed, bid fair to be exciting and strenuous.

Death Certificates Charges Bill.

A Bill to provide "for the reduction in charges for death certificates in certain cases" has been introduced into the House of Commons by Mr. GILL. It has been read a first time. The measure has the support of Mr. A. HENDERSON, Mr. JOHN TAYLOR, Mr. PARKER, Mr. SHACKLETON, Mr. TYSON WILSON, and Mr. JAMES HASLAM.

Three Royal Commissions.

It is officially stated in a Parliamentary paper that the Royal Commission on Vivisection, appointed in 1906, is now engaged in the preparation of its report, but that, in view of points that have arisen, it has appeared desirable to call further evidence. In regard to the Royal Commission on Tuberculosis, the hope is expressed that the work will come to a close and the final report be presented in the autumn of this year. The Commission was appointed by Royal Warrant, dated August 31st, 1901, to inquire with respect to tuberculosis whether the disease in animals and man is the same; whether animals and man can be reciprocally infected with it; and under what conditions, if at all, the transmission of the disease from animals to man takes place. Three interim reports, with an appendix containing details of the experimental work, have already been issued. The Royal Commissioners on Sewage Disposal, appointed in May, 1898, are now investigating the question of the disposal of trade effluents (other than distillery effluents) when not mixed with sewage, and are continuing observations on the effect of discharging effluents of known composition into streams, with a view of reporting more fully on the question of standards and tests. They are also investigating the conditions under which green growths, such as *Ulva latissima*, are fostered in estuaries and how they may be prevented. The interim reports already presented by the Commissioners deal with (1) certain chemical and bacteriological investigations in relation to sewage disposal made under the direction of the Commission; (2) trade effluents and the setting up of rivers boards and a central authority for the purpose of settling disputes between manufacturers and local authorities and for the better protection of rivers and other waters; (3) the dissemination of diseases by means of contaminated shell-fish and other evils caused by the discharge of unpurified sewage and trade effluents into tidal waters; (4) the main question of what methods of sewage disposal may be properly adopted by local authorities; and (5) the disposal of distillery effluents.

HOUSE OF COMMONS.

WEDNESDAY, MARCH 23RD.

Territorial Hospital Arrangements.

Viscount VALENTIA asked the Secretary of State for War, in view of the fact that on mobilisation some county associations were ordered to provide within a week a fully-equipped general hospital, the administrator of which was expected to arrange for having a call upon local tradesmen for hospital equipment, drugs, and surgical appliances, besides fittings for a building in which to store them, that the local tradesmen appeared unwilling to set aside the requisite stock owing to the inconvenience to them of locking up the capital required, and that the county associations were precluded by C. M. 221 from incurring any expenditure on purchase, storage, or other provision for equipment, whether he would consider the necessity for a special grant to be devoted to the above object.—Mr. HALDANE replied: The whole question is under consideration.

Anthrax Outbreaks Amongst Animals.

Mr. BARNSTON asked the Parliamentary Secretary to the Board of Agriculture whether, in view of the increase in the outbreaks of anthrax throughout the country, the Board would institute an inquiry as to the best means of exterminating the disease.—Sir EDWARD STRACHEY answered: The Board's veterinary officers are constantly engaged in making inquiry as to the causes of the spread of this disease, and as to the measures that can most usefully be taken to control it. The Board are also considering what steps can be taken to bring about a more uniform and efficient diagnosis. They do not think that a general inquiry on the subject at the present time would be likely to be attended with any beneficial results.

Chinese Pork in the Isle of Man.

Mr. FELL asked the President of the Local Government Board whether his attention had been called to the promise made by the authorities in the Isle of Man that the Chinese pork which was being cured into bacon there, after being rejected at the ports of London and Liverpool, should not be offered for consumption in that island but should be exported at once; and whether he would take similar action and see that it was not landed in England for consumption.—Mr. BURNS answered: I have no information with regard to the first part of the question. As regards the latter part of the question I may refer the honourable gentleman to my previous replies on this subject.

BOOKS, ETC., RECEIVED.

ALLEN, GEORGE, AND SONS, London.

The Iphigenia in Tauris of Euripides. Translated into English Rhyming Verse, with Explanatory Notes, by Gilbert Murray, LL.D., D.Litt. Price not stated.

ARNOLD, EDWARD, London.

A History of the London Hospital. By E. W. Morris. Price 6*s.* net.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

EVANS, E. LAMING, M.D., B.C. Cantab., F.R.C.S. Eng., has been appointed Surgeon to the Surgical Aid Society, Salisbury-square, E.C.

GRAY, H. M. W., M.B., Ch.B. Aberd., F.R.C.S. Edin., has been appointed Senior Surgeon to the Royal Aberdeen Hospital for Sick Children.

LINDSAY, W. M., M.B., Ch.B. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Biggar District of the county of Lanark.

MARR, JAMESINA J., M.B., Ch.B. Edin., D.P.H., has been appointed Assistant Medical Officer under the Aberdeen School Board scheme of Medical Inspection.

MILNE, MEARNS A., M.B., Ch.B. Aberd., has been appointed Medical Officer to the Craig Parish Council.

POTTS, GEORGE, F.R.C.S. Edin., has been appointed Honorary Aural Surgeon to the Kent County Ophthalmic Hospital, Maidstone.

THOMPSON, HERBERT P., M.D. Edin., F.R.C.S. Edin., has been appointed Honorary Physician to Heatherdene Convalescent Home of the Sunderland Infirmary at Harrogate.

WIGHT, G., M.B., Ch.B. Edin., D.P.H., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Burntisland District of the county of Fife.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BARNSLEY, BECKETT HOSPITAL.—Second House Surgeon, unmarried. Salary £60 per annum, with apartments, board, and laundry.

BERMONDSEY MEDICAL MISSION, 44, Grange-road, Bermondsey, S.E.—Resident Medical Assistant (female). Salary £70 per annum, with board and lodging.

BIRKENHEAD UNION.—Junior Resident Assistant Medical Officer. Salary £100 per annum, with board, washing, and apartments.

BIRMINGHAM, CITY ASYLUM.—Junior Resident Medical Officer, unmarried. Salary £150 per annum, with board, &c.

BRECKNOCK COUNTY AND BOROUGH INFIRMARY.—Resident House Surgeon, unmarried. Salary £120 per annum, with apartments, board, attendance, &c.

BRIGHTON, SUSSEX COUNTY HOSPITAL.—Third House Surgeon, unmarried. Salary £50 per annum, with apartments, board, and laundry.

BRISTOL GENERAL HOSPITAL.—House Physician, Casualty House Surgeon, and Assistant House Physician for six months. Salary £60 each, with board, residence, &c.

CENTRAL LONDON OPHTHALMIC HOSPITAL, Gray's Inn-road, W.C.—Assistant Surgeon.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.—House Surgeon. Salary 40 guineas per annum.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—Clinical Assistant.

CROYDON GENERAL HOSPITAL.—Honorary Radiographer.

DARLINGTON HOSPITAL AND DISPENSARY.—House Surgeon, unmarried. Salary £120 per annum, with board, lodging, and laundry.

EPSOM, LONDON COUNTY ASYLUM, Horton.—Junior Assistant Medical Officer, unmarried. Salary £160 per annum, with board, apartments, and washing.

HAMPSTEAD GENERAL HOSPITAL.—House Physician and House Surgeon, each for six months. Salary at rate of £70 per annum, with board and residence.

HEREFORD COUNTY AND CITY ASYLUM, Burghill, Hereford.—Junior Assistant Medical Officer, unmarried. Salary £120 per annum, with board, apartments, and laundry.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £30, with board and residence. Also Casualty Officer. Salary £200 per annum, with lunch.

HULL, ROYAL INFIRMARY.—Assistant House Surgeon. Salary £80 per annum, with board and lodging.

ILKESTON, BOROUGH OF.—School Medical Officer and Assistant Medical Officer of Health (female). Salary £250 per annum.

LONDON FEVER HOSPITAL, Islington, N.—Honorary Surgeon.

MACCLESFIELD GENERAL INFIRMARY.—Junior House Surgeon. Salary £60 per annum, with board and residence.

MIDDLESEX HOSPITAL, W.—Aural Surgeon. Also Third Assistant in Cancer Research Laboratories. Salary £150 per annum.

NEW HOSPITAL FOR WOMEN.—Surgeon (female).

NOTTINGHAM GENERAL HOSPITAL.—Honorary Physician.

PARISH OF ST. GILES INFIRMARY, Brunswick-square, Camberwell.—Assistant Medical Officer. Salary £120 per annum, with apartments, board, and washing.

POPLAR HOSPITAL FOR ACCIDENTS, Poplar, E.—Assistant House Surgeon for six months. Salary at rate of £80 per annum, with board and residence.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—House Surgeon, House Physician, Junior House Surgeon, and Junior House Physician. Salaries of two former £75 per annum, and of two latter £40 per annum, with residence, board, and laundry.

REETH UNION AND RURAL DISTRICT COUNCIL, Yorkshire.—Medical Officer and Medical Officer of Health. Salary £95 per annum.

ROCHDALE INFIRMARY.—Junior House Surgeon, unmarried. Salary £80 per annum, with board, residence, and laundry.

ROTHERHAM HOSPITAL AND DISPENSARY.—Assistant House Surgeon. Salary £80 per annum, with board, lodgings, and washing.

ROYAL EAR HOSPITAL, Soho.—House Surgeon. Salary £40 per annum.

ROYAL HOSPITAL, Richmond, Surrey.—Assistant House Surgeon. Salary £70 per annum, with board and apartments.

ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, E.C.—Clinical Pathologist. Salary 50 guineas per annum.

ROYAL INSTITUTE OF PUBLIC HEALTH.—Harben Demonstrator of Bacteriology and Comparative Pathology. Salary £250 per annum.

ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Bacteriologist. Salary at rate of £120 per annum, with lunch.

ROYAL NATIONAL ORTHOPÆDIC HOSPITAL.—Resident House Surgeon, unmarried. Salary £100, with rooms, board, and washing.

ROYAL NAVAL MEDICAL SERVICE.—Examination for Fifteen Commissions.

SALFORD ROYAL HOSPITAL.—House Surgeon for six months. Salary at rate of £60 per annum, with board and residence.

SEAMEN'S HOSPITAL SOCIETY, DREADNOUGHT HOSPITAL, Greenwich, S.E.—Assistant Physician.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

SHEFFIELD UNIVERSITY.—Demonstrator in Anatomy. Salary £150 per annum.

SOUTHAMPTON, ROYAL SOUTH HANTS AND SOUTHAMPTON HOSPITAL.—Junior House Surgeon for six months. Salary £60 per annum, with rooms, board, and washing.

SOUTHWARK UNION INFIRMARY, East Dulwich-grove, S.E.—Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

STAFFORD, STAFFORDSHIRE GENERAL INFIRMARY.—Assistant House Surgeon. Salary £82 per annum, with board, residence, and laundry.

STOKE-ON-TRENT, NORTH STAFFORDSHIRE INFIRMARY AND EYE HOSPITAL, Hartshill.—House Physician. Salary £100 per annum, with apartments, board, and washing.

STOW-ON-THE-WOLD RURAL DISTRICT COUNCIL.—Medical Officer of Health. Salary £50 per annum.

TAUNTON, TAUNTON AND SOMERSET HOSPITAL.—Resident Assistant House Surgeon for six months. Salary at rate of £50 per annum, with board, lodging, and laundry.

THROAT HOSPITAL, Golden-square, W.—Resident House Surgeon. Salary £75 per annum, with board and laundry.

UNIVERSITY COLLEGE HOSPITAL.—Mechanical Assistant in Electro-Radiographic Department. Salary £78 per annum, with dinner and tea.

YORK COUNTY HOSPITAL.—House Surgeon. Salary £100 per annum, with board, residence, and washing.

YORK DISPENSARY.—Two Resident Medical Officers, unmarried. Salary £130 per annum, with board, lodging, and attendance.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Ballycastle, in the county of Antrim; at Brackley, in the county of Northampton; at Milnathort, in the county of Kinross; at Salford, in the county of Lancaster; at Henley-on-Thames, in the county of Oxford; at Portishead, in the county of Somerset; and at Denbigh, in the county of Denbigh.

Births, Marriages, and Deaths.

BIRTHS.

MASTERMAN.—On March 5th, at Jerusalem, the wife of E. W. G. Masterman, M.D., F.R.C.S., Medical Superintendent of the English Mission Hospital, Jerusalem, of a son.

REINHARDT.—On March 24th, at South Eaton-place, Eaton-square, S.W., to Dr. and Mrs. Charles Reinhardt—a son (Patrick Hope).

WEBLEY.—On Feb. 19th, at Negritos, Peru, South America, the wife of Arthur S. Webley, L.R.C.P., M.R.C.S., of a son.

MARRIAGES.

BARK—OLIVER.—On March 10th, at St. Luke's, Walton, Liverpool, by the Rev. G. H. Casson, C.M.S., Uganda, Ernest Gilbert Bark, M.B., B.S. Lond., of Liscard, Cheshire, elder son of Ernest Bark, M.R.C.S., L.R.C.P., of Handsworth, Birmingham, to Emily, daughter of Mrs. Oliver, of Walton, and of the late William Oliver.

JAMIESON—GUNN.—At West Coates Parish Church, Edinburgh, on March 16th, 1910, by the Rev. Dr. Forrest, John Alexander Jamieson, M.B., Ch.B. Edin., to Christina Sinclair, elder daughter of James Gunn, Esq., 8, Henderland-road, Murrayfield, Edinburgh.

DEATHS.

BRODIE.—On March 12th, at West Ealing, from pneumonia, William Haig Brodie, M.D. Edin., M.R.C.P. Lond., F.R.C.S. Eng., D.P.H., aged 53 years.

CHEADLE.—On March 25th, at Portman-street, W., Walter Butler Cheadle, M.A., M.D., F.R.C.P., F.R.G.S., in his 75th year.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

MEDICAL PRACTICE IN BASUTOLAND: AN INTERESTING REPORT.

THE report on the Blue-book of Basutoland for the year 1908–09, which has just been presented to Parliament, contains a medical section of unusual interest. It appears that there has been a considerable increase in the smuggling of spirits into the territory, and also that a new form of intoxicant has been introduced from Bechuanaland during the last few years. The local name for this is "Qadi"; it is said to be made from ants' eggs. It has been found necessary to prohibit its use on the Government Reserve owing to its demoralising effect; it produces violent intoxication, and is said seriously to impair the intellects of those who use it habitually. Mr. Edward C. Long, the principal medical officer, comments on the remarkable increase in the work of his department in recent years. Prior to 1890 there were resident medical officers at Maseru and Leribe, a medical missionary subsidised by the Government at Mohales Hoek, and at Mafeteng a medical practitioner from Wepener attended the dispensary once a week. At all these stations free dispensaries for natives were maintained at Government expense. At first but few natives availed themselves of this privilege and the duties of the medical officers were light. In 1890 and 1891 resident medical officers were stationed at Mafeteng and Mohales Hoek respectively. From the latter station Quthing was visited once a fortnight. In 1896 a resident medical officer was placed there. The free dispensaries were inaugurated with the idea of combating witchcraft, which was much practised throughout the territory. The people at first regarded the innovation with suspicion and disfavour, but soon began to appreciate its advantag s, and the number of patients increased rapidly. As years passed it was found that the privilege of free treatment was being abused; it was therefore determined to impose a fee of 6*d.* for each attendance at the dispensary. The annual attendance was at this date about 20,000 and the revenue derived from the department *nil.* The following year the attendance fell to 9000, but has increased year by year, being at the present date over 36,000, the revenue being about £800. In the period about 1890 medical officers had their own private stock of drugs which they used for the few European residents. The system gave rise to a belief in the native mind that the Government drugs were of an inferior quality, and people frequently requested to be treated by the medical officer at his own house. To encourage such a prejudice would have defeated the object with which the dispensaries were inaugurated. The medical officers were therefore instructed to use Government drugs for private work and refund monthly the value of the drugs thus used. This action quickly abolished the prejudice against the Government dispensaries. In 1890 there was practically no accommodation for in-patients except two small rooms attached to the Maseru dispensary and a couple of native huts at Leribe. It was generally supposed that natives would be deterred by superstitious fears from submitting to hospital treatment, but a determined effort was made in the face of great difficulties and discouragement to disprove this and develop some sort of hospital work. It was felt that if the policy aimed at by the Government was to be realised it would be greatly assisted by such means. The actual accommodation at this time was of the meanest description. At Mafeteng for upwards of a year a disused stable was the only building available. There were no hospital attendants and no water-supply. If an operation was performed the dispensary had to be cleared for the purpose and the medical officer's writing-table of the morning was the operation-table of the afternoon. There were no beds and no bedding. Patients lay on mud floors in their own blankets, and their relatives or friends nursed them as they could. From year to year small sums were granted to improve existing buildings and to erect additional accommodation, which, however, continued to be of the most primitive nature. In 1897 a grant of £400 was made for building what were by courtesy called operation rooms at four stations. Some native hospital attendants, a few blankets, and surgical appliances were also provided, and the lack of accommodation eked out by a supply of tents. The applications for hospital treatment continued to increase, and as only surgical cases were admitted the buildings became, if possible, every year more and more unsuited for the purpose for which they were being used. In 1903 the first real advance towards providing suitable accommodation for in-patients was made by the erection at Maseru of a properly built and equipped hospital of 30 beds. An adequate staff, including two trained European nurses, was also provided. The wisdom of this policy was soon manifested; the institution rapidly became popular with the natives, and the beds were always filled. The same liberal policy was pursued in providing hospitals at Leribe in 1906, and last year at Mafeteng, while one now in course of erection at Mohales Hoek will be shortly ready for occupation. A small

hospital of eight beds has also been put up at Quthing. The accommodation at Maseru has been found insufficient, and the provision of 16 additional beds is contemplated. In 1908 an X rays installation was provided at Maseru and has proved of great value. The number of in-patients has risen from 280 in 1899 to 1070 last year. Some criticism has been levelled against the policy of providing first-class accommodation for natives, especially the provision of proper bedding and hospital clothing, and it has been asserted that some simpler accommodation would have met the needs of the case. Five years' experience at Maseru has shown that such criticism is not justifiable. The accommodation and equipment are only such as are necessary to carry out modern surgical methods. There is, moreover, the great educational advantage and civilising influence of compelling all who are admitted into hospital to submit to hospital cleanliness and hospital discipline. Although the equipment is of the best, the patients are not in any sense coddled. Strict discipline is maintained, and the diet is adapted to the social condition of the inmates. Prompt eviction follows any failure to conform to the rules of the institutions. The work of the medical department has grown in other directions. In former years the Government employees, who are all entitled to free medical attendance and medicine, were few in number and mostly unmarried men. At the present day there are over 200 Europeans in receipt of such free attendance. Questions relating to sanitation and public health, which were formerly ignored, now claim a good deal of time and attention. Basutoland is still without any ordinance bearing on sanitation and public health. The unqualified practice of medicine continues throughout the territory, and the annual sum paid by the people to those who impose on them would doubtless suffice to maintain two or three Government institutions. The general health of the territory has been good and there have been no epidemics of importance.

WANTED—TREATMENT FOR "BILIOUS HEADACHE."

"SUBSCRIBER" writes:—"At present I have three female patients, two married with children and one unmarried—the two married are about 38 years of age and the unmaeried 43. They suffer weekly or fortnightly from severe headaches followed by bilious vomiting which lasts from one to two days. I have tried dieting, magnesia and grey powders, citrate of magnesia, citrate of caffeine, bismuth, soda, iron, and arsenic. In the intervals between the attacks the patients are perfectly well and all their organs seem sound. I should be grateful for suggestions for treatment."

CONTRIBUTIONS FROM THE WELLCOME RESEARCH LABORATORIES.

AMONGST the recent researches which form a valuable feature of the work of the Wellcome Laboratories we have received reports upon the following: "The Tests for Purity of Quinine Salts," by Frank Tutin; "The Configuration of Tropine and ψ-tropine and the resolution of Atropine," by Marmaduke Barrowcliff and Frank Tutin; "The Constituents of the Fruit of Ecballium Elaterium," by Frederick B. Power, Ph.D., and Charles W. Moore, Ph.D.; "Syntheses in the Epinephrine Series," by Frank Tutin, Frederic W. Caton, and Archie C. O. Hann; "Chemical Examination of Jalap," by Frederick B. Power, Ph.D., and Harold Rogerson, M.Sc.; and "The Chemical Examination of Elaterium and the Characters of Elaterin," by Frederick B. Power, Ph.D., and Charles W. Moore.

THE HOSPITAL GAZETTES.

THE *pièce de résistance* in the *Charing Cross Hospital Gazette* (March) is a paper on the Mind of a Child by Dr. David Forsyth. The doings of the hospital football team occupy a good proportion of the remaining pages.——As was to be expected, *Guy's Hospital Gazette* (March 19th) also devotes a fair amount of attention to games and includes accounts of the victorious semi-final and final ties for the Rugby Cup as well as that of the semi-final for the Surrey County Association Football Cup, which was won by Guy's against Townley Park after a hard game by 4 goals to 2. Mr. P. H. Ward writes from a mission station in Rhodesia an account of a 12 hours' night journey through the bush in the rainy season to the assistance of a parturient woman only to find a "B.B.A." when he arrived. It is an interesting sketch of frontier practice.——The *London Hospital Gazette* (March) is to be complimented upon the production of an ingenious piece of foolery in connexion with a widely-circulated "picture-puzzle" advertisement on a page apparently produced with the collusion of the advertisers.——In the magazine of the *London School of Medicine for Women* (February) Dr. F. Murray contributes some notes on the Practical Application of Swedish Medical Gymnastics and Massage to some Forms of Deformity and Disease, and an interesting series of topical articles reflects brightly the social life of the school and hospital.——To the *Middlesex Hospital Journal* (March) Mr. A. Pearce Gould contributes some Notes on the Work of Ambrose Parey, and Dr. A. O. English edits Harvey's account of the Autopsy of Old Parr, who, as many people know, is supposed to have lived until his 153rd year after habitually drinking sour milk and to have succumbed at last to the ill-considered hospitality of a nobleman.——*St. Bartholomew's Hospital Journal* (March) contains an account of the patron saint of the hospital, with a plate illustrating Marc D'Agrate's somewhat unpleasant statue of the saint carrying his own skin which stands in Milan Cathedral. "D. M. S." contributes an exciting yachting experience, and "A. B. P. S." a smart copy of verses.——*St. George's Hospital Gazette* (March) also prints verses in which "G. D. H. C." shows the unexpected metrical potentialities of medical nomenclature:—

> "With micro-organisms next you soon get quite familiar,
> Bacillus enteritidis, B. coli, and B.D.,
> The Diplococcus intracellularis meningitidis,
> The Treponema pallidum (a Protozoon, he!)
> Pathologists will tell you of the Endotheliomata,
> Of Lymphatism, Leukanæmia, Splenomegaly;
> Of Hypertrophic Pulmonary Osteo-arthropathy,
> And of Telangiectases, whatever they may be!"

It reads like an incantation.——*St. Mary's Hospital Gazette* (March) contains an extract from the Diary of a Ship's Doctor, following on a paper bearing the curious title of "The Sieve," by Dr. M. Handfield-Jones.——To *St. Thomas's Hospital Gazette* (March) Mr. G. H. Makins contributes some interesting Impressions of American Surgery, recently acquired at Rochester, U.S.A., Chicago, Cleveland, and Baltimore. Of Crile he says: "I saw him do a number of operations, amongst which I may mention as novelties two extensive extirpations of the breast and axillary glands, the wounds in which were left entirely open, in order to allow of direct exposure of the tissues to the action of the X rays. Dr. Crile spoke hopefully of this method, but said it was in the experimental stage."

BOVRIL PICTURES.

WE have received from Bovril, Limited, a signed artist's proof of their latest bonus picture, which is an excellent reproduction of an oil painting by W. Hatherell, R.I., entitled "The Vicar of Wakefield," which was exhibited in the Royal Academy in 1909. The size of the gravure is about 30 × 16½ inches and of the paper about 40 × 30 inches. Messrs. C. W. Faulkner and Co., Ltd., who are responsible for the gravure, are to be congratulated upon the excellence of the reproduction. We have also received three other good reproductions of pictures, two by Mr. Hatherell, of which one is entitled "The King's Derby (1909)" and the other "John Wesley," and one by Arthur Drummond entitled "This Little Piggie."

FORMULÆ, INDICATIONS AND DOSES.

Mr. E. Merck of Darmstadt and 16, Jewry-street, London, E.C., has issued a useful compilation of recent pharmaceutical preparations, and more particularly those to which special attention is given by this firm. The preparations are arranged in alphabetical order and reference to them is made serviceable by the inclusion of a therapeutic index.

Mac.—Our correspondent is advised to have nothing to do with such a publication. His friend should consult a medical man.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

MONDAY.

ODONTOLOGICAL SECTION (Hon. Secretaries—D. P. Gabell, E. B. Dowsett, J. Howard Mummery) at 15, Cavendish-square, W.: at 8 P.M.

Paper:
Dr. R. Ackerley: Observations on the Condition of the Mouth in 1000 Consecutive Cases of Chronic Disease.

Casual Communications:
Mr. Herbert Tilley: Two Cases of Suppurating Dental Cysts Invading the Antrum.
Mr. W. de C. Prideaux: (1) A Case of Vertical Fracture through the Mandible and Canine Tooth; (2) A Case of Rupture of a Gastric Ulcer while in a Dental Chair.

THURSDAY.

EPIDEMIOLOGICAL SECTION (Hon. Secretaries—W. H. Hamer, G. S. Buchanan) at 15, Cavendish-square, W.: at 8.30 P.M.

Paper:
Dr. Niven: Summer Diarrhœa and Enteric Fever.

FRIDAY.

CLINICAL SECTION (Hon. Secretaries: H. D. Rolleston, Albert Carless) at 15, Cavendish-square, W.: at 8.30 P.M.

Cases:
Dr. Finzi (with Mr. Gordon Watson): A Case of Epithelioma of the Lip treated with Radium (shown a year ago).
Dr. Finzi (with Dr. William Hill): Malignant Growth of Neck treated with Radium, with Recurrence in Mediastinum.
Mr. Charters Symonds: Rodent Ulcer treated by Radium (shown before).
Dr. Jacob: Acholuric Jaundice.
Dr. Hertz and Dr. F. S. Adams: Formation of Gallstones containing Typhoid Bacilli within 68 Days of the Onset of Typhoid Fever.
And other Cases.

NORTH-EAST LONDON CLINICAL SOCIETY, Prince of Wales's Hospital, Tottenham, N.

THURSDAY.—4.15 P.M., Discussion on Vaccine Therapy (opened by Dr. G. Macdonald).

SOCIETY OF MEDICAL OFFICERS OF HEALTH, 1, Upper Montague-street, Russell-square, W.C.

FRIDAY.—5 P.M., Mr. C. S. Loch: The Majority Report of the Royal Commission on the Poor Law.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Mr. C. Nourse: External and Middle Ear.

FRIDAY.—3.45 P.M., Lecture:—Mr. C. Nourse: External and Middle Ear.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (4th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. THURSDAY (7th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, (9 A.M., Major, 2 P.M.).

FRIDAY (8th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.) Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor 9 A.M., Major, 2 P.M.).

SATURDAY (9th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs. 50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnières, Paris.

The Lumleian Lectures
ON
ANGINA PECTORIS.

Delivered before the Royal College of Physicians of London

BY WILLIAM OSLER, M.D., F.R.S.,
REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF OXFORD.

LECTURE III.[1]

Delivered on March 17th.

PROGNOSIS.

MR. PRESIDENT AND FELLOWS,—How well the introduction to the "Prognostics" fits angina pectoris! A very excellent thing is it indeed, Hippocrates says, for the physician to cultivate prognosis, and nothing so much inspires confidence as the power of foreseeing and foretelling in the presence of the sick the present, the past, and the future, and he will indeed manage the cure best who has foreseen what is to happen. And almost as if he had this very disease in view he adds: "For it is impossible to make all the sick well; this indeed would have been better than to be able to foretell what is going to happen; but since men die, some even before calling the physician, from the violence of the disease, and some die immediately after calling him, having lived perhaps only one day, or a little longer, and before the physician could bring his art to counteract the disease, it therefore becomes necessary to know the nature of such affections."

The essence of prognosis lies in recognising, as Hippocrates says, "the nature of affection." And yet the thought must arise how futile to discuss the future in a disease, aptly described in so large a number of cases in Sencea's words as "meditatio mortis." I am sorry my figures do not allow me to agree with my brother regius of Cambridge, that of "all perilous maladies it [angina pectoris] is perhaps the most curable."

A consultant has great difficulty in making his experience of any disease effective, particularly in this matter of prognosis. A patient seen once or twice arouses intense interest, and then vanishes from his clinical ken, and the oft-repeated impressions of other cases leave a blurred image like that of a composite photograph. My practice was to get the notes of each angina case in good order at once, typewritten, and filed away, and then at intervals my secretary could write to the medical man in charge and add a note on the patient's condition.

It takes courage to make a prognosis. Fulness of knowledge does not always bring confidence; the more one knows the more timidity may grow. The faculty which enables a man to look all round a question, to take a philosophical view of it, may be tempered with doubt, and an inability to reach a conclusion. A cocksure diagnosis and a positive prognosis may express the assurance of ignorance. In reviewing a long series, the high mortality and the great frequency of sudden death give a sombre tint to the picture, and yet I shall hope to show you plenty of bright patches. Seeing the more severe cases, the experience of the consultant is apt to be misleading, nor is always the lesson of his mistakes so thoroughly learned as by the general practitioner who lives in the same town with them. To know of the future is naturally the ardent desire of the patient and his friends, and whether we like it or not an opinion must be expressed. Sometimes out of pure kindness the tongue belies the head and always the great aphorism rings its warning—Experience is fallacious and judgment difficult. Now that we know more of the diagnosis of disease we talk less about prognosis, and to be of any value the latter must follow the former and grow out of it naturally. Often the one thing needful, the diagnosis, may embrace both prognosis and treatment; more than once this has happened in connexion with the disease under consideration. The first step is to get a clear idea of the nature of the affection—Is it an expression of organic disease of heart or arteries or is it only a painful disturbance of vascular function?

[1] Lectures I. and II. were published in THE LANCET of March 12th (p. 697) and 19th (p. 839), 1910, respectively.

PROGNOSIS IN RELATION TO ETIOLOGY.

From the standpoint of prognosis the disease may be studied in various ways. Naturally the most important consideration relates to etiology. In any case three questions are suggested: Is it syphilitic mesaortitis? Are the arteries involved in a general or local sclerosis? Is it a so-called functional condition unassociated with organic lesion of the arteries?

Syphilis is of the first importance, and we have learned to recognise the frequency with which this disease attacks the root of the aorta, causing angina pectoris, aortic insufficiency, or aneurysm. In 17 cases of my series there was a history of syphilis, and it is interesting to note that a majority of the patients were under 45 years of age. In many of the cases it was not possible to connect the attacks directly with the disease. I have already spoken of the lesion—a mesaortitis—sometimes limited to the supra-sigmoidal area. A characteristic paroxysm may be the first symptom; a patient may, indeed, die in the initial attack. Nothing may be detected on physical examination; there may, perhaps, be slight superficial tenderness on pressure over the region of the aorta. Insufficiency of the valves may come on under observation. A striking result of the extended use of Wassermann's reaction has been to show the importance of syphilis in aortic valve disease. The disease is not always confined to the root of the aorta; in three of my patients it was of the diffuse sclerotic type without special limitation. The prognosis is often very favourable.

The first case of angina pectoris I saw in Baltimore was a lieutenant in the navy, aged 30 years, who had had syphilis six years before. For a year he had attacks and had had to be off duty for many months. There was no enlargement of the heart, but there were systolic murmurs at both mitral and aortic areas. With the iodide of potassium he improved sufficiently to return to duty. After having lost sight of him for many years I then heard of him again, that he had remained perfectly well. A man, aged 58 years, seen on Oct. 28th, 1904, had severe attacks with moderate arteriosclerosis. I would not have recognised the specific nature of his trouble had I not seen him in 1898 with a most interesting syphilitic nephritis and periosteal nodes. The blood pressure was high, the aortic second sound ringing; but it was a favourable circumstance that the albuminuria had disappeared. He stood an anti-syphilitic treatment very well, progressively improved, the attacks gradually lessened, and he has remained well.

It is not always easy to determine whether or not syphilis is a factor, and yet it is well to give the patient the benefit of the doubt. A man, aged 56 years, who had had for three months very characteristic anginal attacks, had lived just the sort of life likely to bring them on—a gross eater, hard worker, heavy smoker, and yet the arteries were not specially sclerotic; the heart was not enlarged and the sounds were clear. He had had syphilis 30 years before. He improved with the use of iodide of potassium, and had no attacks for more than four years. I saw him very frequently, and it was not always possible to keep him in the "straight and narrow way." He died suddenly one night, probably in an attack, before a medical man could reach him.

In persons under 40 years of age it is always well to bear in mind the possibility of syphilis. A woman, aged 37 years, whose case had been a great anxiety, had paroxysms of angina with hypertension and acute pulmonary symptoms. There was no doubt as to the severity of the disease. The question of syphilis had not been discussed until she complained of an ulceration of the throat, which Dr. Warfield at once diagnosed as syphilitic. The transformation in a month was nothing less than marvellous. I had not thought of a possibility of her recovery.

The outlook is not always so satisfactory. I followed for a couple of years, with Dr. Julius Friedenwald, the various phases of aortic root syphilis in a man, aged 36 years, who had paroxysms of great severity, often associated with collapse, and once on the street with unconsciousness. Aortic insufficiency arose under observation. When I saw him on Feb. 2nd, 1904, he was having attacks every day, and could not walk more than 100 yards without pain and oppression in the chest, "as though there was a stone under the breast-bone growing larger and larger." Marked improvement followed anti-syphilitic treatment, and he was able to go back to his business for a year or more, and was

comparatively free. Then, in spite of vigorous treatment, the attacks returned, and finally in one of them he died.

The sclerotic aortitis may be the only lesion. John W., aged 24 years, a farmer, died in an angina attack, of which he had three or four during the fortnight. He was admitted to the hospital on May 25th, and died on June 8th, so that his illness did not last more than three and a half weeks. He had had syphilis nine years before. He was a healthy, muscular fellow, with a good pulse, sclerotic arteries, and an apex-beat a little out from the normal position. The attacks were severe, and in one he died suddenly. Beyond dilatation of the chambers and some chronic passive congestion there was nothing special; the valves were normal, the orifices not narrowed; characteristic sclerotic aortitis involved the entire vessel. Many of the smaller arteries were thickened.

INDIVIDUAL HISTORY, CHARACTER OF ATTACKS, AND VASCULAR CONDITION.

"The cardinal fact in the prognosis of real angina is its uncertainty," with which statement of Walshe we all agree, and further he confessed that he knew no method by which we can reasonably tell whether a sufferer will be cut off the next minute or survive many years. The individual history, the character of the attacks, and the vascular condition are the important elements in the prognosis—taking it for what it is worth.

Much depends on the patient himself—on the life he has led—the life he is willing to lead. The ordinary high-pressure business or professional man may find relief, or even cure, in the simple process of slowing the engines, reducing the speed from the 25 knots an hour of a *Lusitania* to the 10 knots of a "black Bilbao tramp." The difficulty is to induce a man of this type to lessen "the race, an' rack, an' strain." As William Pepper used to say: "Give me the life of a hare rather than the existence of a tortoise." Not even the terrible outbursts of pain may suffice to check men of this stamp, and yet, like Kipling's ship, *The Haliotis*, many a sensible fellow, whose engines at 50 or 55 years of age had gone to pieces on the "long trail, the out trail," has been refitted and enabled to reach port in safety. We doctors are notorious sinners in this respect, but it is so hard to lessen work when in full swing, so much harder than to give up altogether, and how few of us at 50 or 55 are able to do this! A severe attack of angina may save a man's life. A Congressman had burnt the candle at both ends—work and whisky, wine and women, had made a wreck of him at 49; and a spree culminated in a paroxysm of angina in which he nearly died. Five years subsequently he was in excellent health, in spite of a high blood pressure and moderate sclerosis of the arteries. He dated the change of life from the attack which had frightened him into sobriety. A group of most encouraging cases show that long intervals of good health, and even complete freedom, may follow the adoption of reasonable habits. Let me refer to one or two. Last summer I met in London a distinguished American lawyer, whom I had seen ten years ago in a series of severe attacks, one of which nearly proved fatal. Following in the track of the intercostal pain he had an outbreak of herpes, the only instance I have seen of this complication. After six months' rest he resumed work at an easy pace. I saw in the papers a few weeks ago the death of General P. whom I saw in 1901, then aged 65 years. For two months he had attacks of angina, and once had a succession of paroxysms which kept him in bed for three days.

Not much stress can be laid on the character of the attack so far as the ultimate outlook is concerned. The immediate prospect is always doubtful; a mild paroxysm may be succeeded by a severe one, or death may occur with the appalling suddenness which is one of the features of the disease. The vaso-vagal features—pallor, sweating, faintness, and nausea—are serious in proportion to their prolongation and to the resistance they display to remedies. A man may come out of a state which seems absolutely desperate. One does not often see recovery and subsequent good health after such a paroxysm as in the following case, which was studied with great interest by Dr. McCrae and myself.

J. H. W., aged 60 years, admitted to a private ward on March 24th, 1904, was a vigorous, active man, the victim of many acute infections, but not syphilis. He had taken an average quantity of whisky and had worked hard. In June, 1902, when salmon-fishing, he had his first attack, then a second one in January, 1904; a third on Feb. 22nd, which was very severe, as he lost consciousness; a fourth on March 10th, also very severe; and a fifth a few days before he came into the hospital. He was a robust, healthy-looking man with a good colour, a feeble heart impulse, no superficial heart dulness, distant sounds; pulse of good volume, slightly irregular; marked sclerosis of the arteries. On April 4th at 1 P.M. he had an attack in which he looked as if he were dying; the hands and feet were cold and clammy, and at intervals he sighed deeply and threw up the chin; he was conscious; the pulse was from 42 to 48, regular but small; the heart sounds were feeble and distant. By 1.30 the ashen grey colour was replaced by slight lividity; the pulse rose to 52; the blood pressure was 120 mm. of mercury. At 2 o'clock the pulse was 60, better, quieter, and there was less cyanosis. At 2.30 the pulse was 68; he vomited several times, and at intervals had very deep sighing respirations. He was in a very critical condition all the afternoon, but gradually improved. Two days later, at 1.30 A.M., he had a mild attack of pain in the region of the heart with intermittency of the impulse. He gradually improved and left the hospital on June 23rd. Through Dr. McCrae I have heard from him at intervals, and he has kept very well. This man had six severe cardiac attacks, in one of which he nearly died, and yet he has now remained well and active for the past six years.

In the attack itself there are two bad prognostic signs—disturbance of respiration and slow, irregular heart action. The acute orthopnœa with signs of emphysema and œdema of the lung is serious, and not met with except in grave cases. Death may occur or the attacks may replace those of angina. Slow, grasping breathing, particularly if the patient has become unconscious, is of bad omen. Cheyne-Stokes respiration, a frequent accompaniment, is a bad sign when it comes on in a man who has not had it previously, in connexion with cardio-vascular or renal disease. The state of the heart is very deceptive. A man may die shortly after an apparently satisfactory examination. Listen to this report, jotted down at the bedside of a man in an attack, and who died five hours subsequently. "Pulse 92, at first regular and of good volume, but subsequently one or two beats dropped. There is nothing to attract one's attention in the pulse itself. (The blood pressure taken in the same afternoon was 160 mm. of Hg.) The arteries are not sclerotic; the apex beat is not visible; and between a high stomach tympany and an inflated edge of the lung it is not easy to make out the heart limits; the sounds are clear at apex and base, a beat drops occasionally; there is no gallop rhythm, nothing to indicate any serious disturbance; there is no heightened sensibility of the skin over the heart." This man had had anginal attacks on and off for a year. The heart was working with not more than 30 per cent. of a coronary circulation; one main stem was entirely obliterated, the other partially.

The small, feeble, rapid pulse is not of such ill omen as one of fuller volume, with marked arrhythmia; and a slow pulse with unconsciousness is always of grave import.

The circumstances that bring on an attack are almost of as much moment in the prognosis as its character. We all recognise the three chief factors—emotion, distension of the stomach, and muscular effort. Of the three emotion is of the least significance. Many instances of slight anginal attacks are brought on by anger, worry, or sudden shock; and while in individual cases they may be serious, yet the cause is rather easier to avoid, and always has seemed to me to be less dangerous, though John Hunter neither thought so nor found it so. In many elderly persons with stiff arteries the commonest cause is stomach disturbance; a full meal, indigestion, flatulence, particularly at nights, is certain to bring on an attack. And there are individuals who are sensitive to this cause only. As one patient expressed it: "Had I not to eat I never would suffer."

The angina of effort, the paroxysm that comes on invariably after a man walks a few hundred yards or after using his arms, is a coronary artery affair, and is, as a rule, more serious than that which comes on spontaneously or as a result of emotion. This feature is the most common indication of what you, Sir, call "primary cardiac angina." The parallel between the angina of effort and intermittent claudication has often been drawn, though the cardinal difficulty has been pointed out that in the one case a man stops walking, in the other the heart continues to work. A curious feature in some cases of this type is that a man

may be able to walk freely in his place of business, or in his house, and not be able to do so on the street. While constituting some of the most distressing cases, since even the act of dressing may bring on pain (*angor de toilette*), yet life may be prolonged, as in the case I mentioned of the man who had been a victim for some 11 years, and whose coronary arteries were calcified to their finest ramifications.

And the third important factor in prognosis is the patient's cardio-vascular condition. Persistent high tension with marked sclerosis of the arteries occurs in a very large group of cases, but it is important not to over-estimate their seriousness. The outlook may depend much less upon the existence of these factors than on the sort of man in control of them. An engineer of the "McAndrew" type will so handle his machine that the ship makes the voyage round the Horn to London with safety; whereas a man of a different type will wreck the engines and leave his ship a derelict. A large majority of all cases of angina pectoris have no obvious signs of disease of the heart itself. Of valvular lesions the aortic alone is important—insufficiency in the young man usually means syphilis; stenosis in the old means calcified aorta, narrowed coronary orifices, and rigid coronary arteries. Disease of the aorta itself is not often recognised. The prognosis of cases of aneurysm beginning with angina is, of course, serious, though as the sac grows the attacks may disappear.

FORMS OF ANGINA PECTORIS.

It was a distinguished President of this College, John Latham, who in 1812, I believe, first recognised that "certain symptoms did not always denote angina pectoris," and spoke of angina notha; and it is a useful division which recognises a minor and major type of the disease—or what I think is still better, a form without, and a form with, organic lesion of the cardio-vascular apparatus. A diagnosis of these two forms from each other is an essential preliminary to successful prognosis. It may have surprised some of you that the number of cases of mild or functional angina in my list was so small, but I carefully excluded all trifling forms of heart pain in nervous women, and have only considered the cases which presented the features of an anginal paroxysm. Of the 43 cases there were 23 in women, not so large a percentage as given by many authors. It is a useful division to group the cases of this type into the neurotic and toxic; the former occur much more commonly in women and the latter in men. In looking over the histories of 14 cases of the severer organic angina pectoris in women I see that in only two or three cases was the diagnosis in doubt. The average age was much above the other group—56 years. In not a single instance was there absence of sclerosis, high pressure, or heart disease, and the character of the attack in almost every instance stamped the nature of the case. I have more frequently mistaken organic angina for the functional form than *vice versâ*. Two of my worst mistakes were in medical men, and for their sakes I did not regret it, since both derived great comfort from the thought that they were not the subjects of angina vera. One man would have deceived Heberden himself, as he had hysterical attacks, at any rate, nervous outbreaks with spasm of the larynx, a sort of child-crowing, and a nervous dysphagia. Let me read the note I dictated at the end of his report:—"Against recurring attacks of moderate severity in a man of 53 must be balanced a healthy heart, a very nervous temperament, and the occurrence of laryngeal and œsophageal spasm. The patient is very apprehensive and feels sure he is going to die. I think the balance is in favour of a neurotic, functional condition." I was wrong; three years subsequently he died in an attack. The other patient had not a trace of obvious organic disease, but he had driven his engines very hard. He had smoked excessively, and at the time of the attack was very emotional. He improved so much that we all congratulated ourselves upon the correctness of our treatment and diagnosis. He dropped dead while speaking at the telephone.

Many subdivisions have been made of the neurotic form, but for prognosis they roughly fall into two, the distinction between which is the predominance of the vaso-constrictor or vaso-dilator phenomena. Many cases resemble what Gowers describes as vaso-vagal storms. Beginning with coldness of the hands and feet, numbness and tingling, with small pulse, pains are complained of in the heart itself, often more to the left, and in the pectoral rather than in the sternal region; the radiation may be marked, up the neck and down the arm, and much more than in the organic form superficial sensitiveness of the skin is noted. The attacks may pass off in the course of an hour or two, but in the severe ones there may be nausea and vomiting; the respiration is quickened, and there is an indescribable sense of fear and dread. With it all the patient may move about, and there is rarely present the characteristic immobility of the severe forms.

When the vaso-dilator features predominate the patient complains of fulness in the head, of a terrible distress in the back of the neck, or a general sense of superficial tension. As one woman expressed it: "I feel just like an inflated balloon on the point of bursting." The heart's action may be forcible, and there is widespread throbbing of the arteries. The face and hands may be congested and hot, the face sometimes slightly livid. Following these symptoms, or coming on at the same time, the patient begins to have heart pain, which may become very severe; the lines of radiation may be characteristic, and with these symptoms there may be remarkable prostration. One patient whom I saw very often in this type of attack never had cold hands or cold feet, and on several occasions so distended was the superficial vascular system that bleeding was suggested, but she would never consent. There is rarely much difficulty in determining the character of these attacks, with which are often associated neurasthenia and hysteria. Occasionally one meets with paroxysms of great intensity, in which as the pain reaches a maximum the patient is thrown into a sort of tetany. In a man aged 32 years, whose troubles began with palpitation, the pain was apparently very severe, and he had stiffness and cramp of the fingers, a sort of tetany in which they could not be moved. Sometimes he would get into a state of general rigidity, all the time complaining of terrible agony in his heart. Many patients have phobiæ.

The majority of these cases do well, and it sometimes happens, particularly in a man, that a reassuring diagnosis is all the treatment required. In attacks of extraordinary severity a fatal event may happen, as in the patient of Dr. Bullard, to which I referred in the last lecture. While gradual recovery in the course of a few months or a year is the rule, some cases are very obstinate. A man of 28, who had not worked for five years owing to constant recurrences of pain in the heart and along the inner side of the left arm, was exceedingly nervous, and after months of treatment we could do nothing with him. As he wrote pathetically: "I heard you say to the students that there was nothing wrong with my heart, but if you had it for a few nights and felt the pain in it, you would think quite differently."

The worst sort of neurotic angina may follow influenza, and the rapid recurrence of the paroxysms may render a man's life unbearable. An old student and valued friend in practice near Philadelphia, who was a little nervous and had occasionally had migraine, a month after influenza began to have the most extraordinary attacks. The pallor and coldness of his extremities exceeded anything I have ever witnessed; nothing could warm them; even after his legs had been for 15 minutes in water as hot as he could bear, when taken out he complained that they felt cold. In the attacks the mental distress was agonising, and he had a sense of terrible constriction across the upper part of the chest. He threw himself about the bed, and the condition was most painful to witness. He gradually recovered.

My experience of an angina which may be termed toxic is very limited. I have not seen more than a dozen instances in which to tea, coffee, or tobacco could the attacks be attributed. We may look forward to an increasing number of cases of heart pain, and of the mild type of angina in women, with the rapid increase of cigarette smoking. I saw last winter in Italy an American woman whose daily allowance of cigarettes was never under 25. She had an unusual feature—cardiac pain only after rising from a recumbent posture, and this would worry her for half an hour, so that it made dressing in the morning difficult.

It is interesting to note that very heavy smokers may die a vagus inhibition death, just such as we see in angina pectoris. Three robust, healthy persons of my acquaintance, not known to have had heart disease, but all incessant smokers of very strong cigars, died suddenly in this way, without warning—one aged 53 while walking; one a man of 36 fell off a chair at his club; the other a man of 38 died on the beach after bathing.

TREATMENT.

A retrospect of one's experience in treatment will be coloured by the general character of the special disease under consideration. I look back with unmixed satisfaction at my experience with typhoid fever, every aspect of which may indeed be dwelt upon with pride by every member of the profession. On the other hand, pneumonia arouses feelings, also unmixed, but of a totally opposite kind. There have been certain gains: we know our enemy better, but there is no pleasure to be had in looking back upon the record. And the other night, in going over case after case of my typewritten reports, I could not help taking stock in this way of angina pectoris. And on the whole, in spite of the frequency of the broad arrow, the feeling was one of satisfaction. Terrible as it is in certain aspects, angina has many circumstances in its favour: it kills late, it kills quickly, we are able to do much to lessen the sufferings of the victims, and we cure a certain number of cases. There are but few deaths under 40 years of age; no known disease kills so peacefully, so painlessly, and there has been real and solid progress in the advance of our knowledge of how to treat it.

As with prognosis, so with treatment: there are three great groups to be considered—syphilitic, neurotic, and arterio-sclerotic.

When a man gets a specific aortitis it means he has not had efficient treatment. There is nothing in the lesion of the arterial wall which mercury and iodide of potassium cannot control. The spirochætæ excite a diffuse granulomatous mesaortitis, with destruction of muscle and elastic fibres, and the chief difficulty arises from its insidious progress, so that irreparable damage may be done before any warning is given. The details of treatment offer nothing upon which I need dwell in this audience. The value of mercury, no matter what the stage of the syphilis, is emphasised when one actually sees the spirochætæ in large numbers in the aortic wall, as has been demonstrated by J. H. Wright, since so far as we know the metallic drug alone acts as a specific. Iodide of potassium clears up the exudate and, as is well known, will cause a node to melt away even faster than will mercury. One thing, too, it does with almost invariable success—relieves pain. Here is the secret of its great influence in aneurysm in which in the early stage it is as good as morphia in giving relief, clearing the exudate in the media and adventitia, and in this way relieving the pressure on the nerve elements.

In the neurotic cases, with a recognition of a basic disturbance in the vaso-motor apparatus, the treatment is most satisfactory, and only a few cases prove refractory. A modified Weir-Mitchell cure with hydrotherapy meets the important indication. Long experience has taught the value of the wet pack in restoring stability in vascular ataxia. Counter irritation over the heart is sometimes helpful. Of drugs the patients have usually had enough by the time they reach the consultant, and one part of the battle is to wean them from all sorts of mixtures. One patient laid out before me 22 prescriptions, and was much aggrieved not to have a twenty-third. Sometimes a reassuring diagnosis is the only treatment needed. I have always been sorry that an article on angina pectoris was in the "British Encyclopædia," since it has helped to make the very name deadly in the ears of the public; and there is an advantage in speaking to nervous patients of a false variety, which may mimic every phase of the true disease. When high tension is present, which is not infrequently the case in neurasthenia, the nitrites are helpful, and they have a very special value in the toxic forms, particularly that due to tobacco. In the cases with extreme vaso-motor ataxia I have long used the extract of ergot (ergotin) with advantage two or three grains three times a day.

I have nothing to add to the general knowledge which we all have of the treatment of the severer type of the disease, but I may give you my experience very briefly: first of the treatment of the paroxysm itself and then of the general conditions out of which it arises. It was not to be expected that our generation could have in any one disease a second therapeutic boon of equal importance to that given us by our distinguished Fellow, Lauder Brunton. Of the value of amyl nitrite in loosening arterial spasm and relieving the tension and strain upon which the pain depends we are all agreed We see its remarkable benefit, more particularly in the cases which begin with a widespread vaso-constrictor influence. Many practitioners express disappointment that it does not always relieve the pain promptly in the severe paroxysms; but it is not itself an analgesic, but only loosens the muscle grip; and it may well be that the painful effect of the disturbance of tension may persist after the spasm itself has disappeared. At any rate, experience teaches us that we often have to resort to morphia to relieve the atrocious character of the pain. Moderate doses, as a rule, suffice; but it is to be remembered that, as Burney Yeo pointed out, there are cases extraordinarily resistant; and I have reported an instance of status anginosus in which, between 10 o'clock on Saturday night and 1 P.M. on Sunday, five grains of morphia were given hypodermically and by the mouth with relief of the pain, but without giving sleep. In these terrible cases, in which attack follows attack, the nitrites are of as little use as water. In despair one may have to resort to chloroform. I well remember to have done so at first with fear and trembling, as the patient's heart was feeble, but it seemed imperative to give the poor fellow relief. I have used it many times since, and never with ill effects; in no case did sudden death occur during the administration or immediately after it. Theoretically the practice is a risky one, but neither in my hands nor in those of the late George Balfour of Edinburgh were there ill consequences.

Oxygen inhalations are useful, particularly when there is a dusky cyanosis and in the asthma-like dyspnœa. In the weak, failing, irregular heart one is tempted to give digitalis, and it may be tried, preferably by the hypodermic method. There is one type of case in which the drug should be used—when marked cardiac weakness follows an acute single attack in a comparatively healthy man. Post-mortem experience shows that the lesion in such a case is very likely to be blocking one of the coronary vessels. While anatomically the coronaries are not endarteries, functionally they are, and an infarct is, we know, very apt to follow; and if after the attack a pericardial rub is heard we may be certain this has happened. By maintaining the pressure within the myocardial vessels the extent of the anæmic necrosis may be lessened.

For the general condition the value of iodide of potassium in arterial lesions, and specially in the syphilitic variety, is universally recognised, and it may be given at intervals for months. Last winter I had an interesting talk with the distinguished Roman clinician Marchiafava, whose experience in angina pectoris is very large, and he gave me reports on cases treated with theobromia, from 20 to 30 grains in the day. A number of them were greatly benefited. I have only had the opportunity of trying it twice; in one case the use had to be interrupted on account of a complication; the other patient has been remarkably helped, particularly in the capacity of taking more exercise.

In the middle-aged man who has had an attack of angina it is usually a question of high tension with beginning or actual sclerosis of the arteries. So soon as a man has crossed that point in life when the pace is the fastest, whether we put it at 25 with Plato, at 40 with Montaigne, or to be more kind, let us put it with the sexagenarian himself, at the grand climacteric (63), the tubing begins to show signs of wear and tear, and the blood pressure gradually rises. Now there is nothing more difficult than permanently to reduce persistent high blood pressure. Drugs have really very little influence. The nitrites are helpful in temporarily lowering it; but take a man with a persistent pressure of 230 to 240 mm. of Hg, and you may get the record to 210 or 220, but to get it back to 150 or 160 and keep it there is not often within our power. Much more important results may follow change in a man's habits of life. I usually give two prescriptions—"Go slowly," "Eat less"—on which I find a great many patients put about the same value as did Naaman on the prescription of Elisha. A man who has kept a full head of steam in the boilers must learn to lower the pressure and be content with the quiet 10 knots an hour speed. It is very difficult to stoke the engines in due proportion to the work expected. No wonder there is high pressure and the machine goes to pieces when the furnaces are stoked for the *Lusitania* and the engines are asked to do the work of an ordinary ocean tramp. Like longevity, angina pectoris is largely a question of the arteries. It is an old story, this association of a long life with a small intake, a story well told by Cornaro in the sixteenth century,

and in our own day by our own Cornaro, Sir Herman Weber.

If, Mr. President, I have dealt with this important subject in a somewhat sketchy manner my apology must be that before such an audience I could not discuss trite and every-day features of so familiar a disease, so I thought it would be more interesting to give you my personal experience. It adds salt to life when men react differently to the same impressions. It is always with a shade of regret to find a colleague of the same way of thinking with myself on every question, so that I hope you have not all agreed with all of my conclusions. At any rate, Sir, mindful of the wise counsel of Lucretius, I have tried not to base wide opinions on small *signs*, and so involve myself in the snare of self-deceit.

ABSTRACT OF THE

Hunterian Lectures

ON

THE SURGERY OF THE LYMPHATIC SYSTEM.

Delivered at the Royal College of Surgeons of England on Feb. 23rd and 25th, 1910,

BY W. SAMPSON HANDLEY, M.S. LOND., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND; ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL.

LECTURE I.

Delivered on Feb. 23rd.

GENTLEMEN,—The rudimentary condition of lymphatic surgery is shown by the almost exclusively ablational methods hitherto employed. Thus, amputation or excision of the diseased tissue have been the methods of choice for lymphatic œdema of the tissues, while serous effusions are run to waste through a cannula. The conservative phase of lymphatic surgery is that to which I shall mainly direct your attention. For the aspect of the subject is being changed by the idea of the internal drainage of serous effusions introduced into it by my colleague, Dr. W. Essex Wynter, and by the use of capillary attraction along silk threads as a substitute for destroyed lymphatic vessels in lymphatic œdema, a method which I introduced two years ago. My material divides itself into three sections: (1) the surgery of lymphatic œdema; (2) the surgery of serous effusions; and (3) cancer surgery as a branch of the ablational side of lymphatic surgery. We will first consider the various forms of lymphatic œdema.

SOLID ŒDEMA DUE TO CANCER.

Dropsy associated with cancer may show itself as a serous effusion in the pleura or peritoneum, or as a local œdema. In the latter form it is most frequently seen in the arm. Less commonly it occurs upon the chest, for, as I have shown, in its early stage, *cancer en cuirasse* is simply a lymphatic œdema of the skin, and no cancerous elements are at first present in the thickened skin. I show you two sections of the thickened skin to illustrate this fact.

THE BRAWNY OR DROPSICAL ARM OF BREAST CANCER.

A brawny arm develops in 16 per cent. of all cases of breast cancer. Its frequent occurrence depends upon the commencement of the growth in a situation close to the root of the limb, conveniently placed to menace its lines of ymphatic communication. The œdema often commences as a general swelling of the whole limb. In some cases it begins at the wrist and travels upwards; less commonly it begins at the shoulder and travels downwards, or it may first be noticed at the back of the elbow. In some cases a sharp line of demarcation in the deltoid region separates the swelling from the normal tissues above. In other cases the shoulder shares in the swelling, which may in a late stage extend to the thoracic wall or to the opposite breast. Of 15 cases in which I have done lymphangioplasty in breast cancer, 8 have been on the right and 7 on the left side. Of 54 cases of brawny arm of which, apart from my operative series, I possess notes, 34 have been on the left side and 20 on the right side. The condition thus appears to be commoner on the left side. Occasionally in association with cuirass cancer both arms are affected.

Dropsical arm is associated with the more chronic forms of breast cancer. In the cases upon which I have operated an average period of six and a half years elapsed between the first sign of cancer and the development of the swollen arm. In one case the swelling took 13 years to develop, in two others 11 years. At the opposite end of the scale are two cases in which only six and nine months respectively intervened between the onset of breast cancer and the swelling of the arm. The period of survival which may be expected after a dropsical arm has appeared is difficult to determine, but is not a long one, and probably averages under one year, though in very chronic cases it may exceed three years. Into this short period is usually crowded most of the physical agony caused by the disease. The dropsical arm acquires most of its importance from the excruciating pain which it causes—a pain which in the worst cases almost passes the limits of endurance. This pain is referred to the whole limb, and varies from a dull ache to an intolerable burning agony. It is accompanied by a heavy, leaden drag, due to the weight of the limb. The pain varies in intensity, and there may at first be periods of complete intermission. In several of my cases the pain, though diffuse, has been much worse in the palm of the hand than elsewhere. After a time paralysis of the limb supervenes. The movements of the fingers are the last to be lost. The œdema interferes with passive as well as with active movements of the joints. The elbow is usually held in a position of slight flexion, and can be moved only through a small arc of 30 degrees or less. The wrist and fingers are also stiff, and when the œdema affects the shoulder vertical movements of the scapula upon the chest are prevented. Lastly, the arm may be deeply cyanosed.

PATHOLOGY OF THE DROPSICAL ARM OF BREAST CANCER.

Among the general factors which may contribute towards the appearance of dropsy in cancer is the watery state of the blood plasma demonstrated by Dr. J. J. Douglas, which acts in two ways—by diminishing transudation and by hindering absorption through the capillary walls. But the strict localisation of the area of œdema in brawny arm shows that local, not general, factors are the chief agents at work. The swelling was formerly considered to be caused by venous obstruction, and to result from the pressure of growth upon the axillary veins. Various considerations show the incorrectness of this belief. The fact appears to be that the venous obstruction in cases of dropsical arm is not the cause of, but is caused by, the dropsy. It has been shown by Professor E. H. Starling that if fluid is injected into the subcutaneous tissues of an animal's leg, obstruction or occlusion of the veins may be produced. The rise of pressure thus produced in the capillaries tends in its turn to increase the transudation of lymph and to aggravate the dropsy, and thus a vicious circle is set up. The return of the cyanosed limb to its normal colour within a few days of the operation of lymphangioplasty, which I have observed on more than one occasion, is an experimental proof of the truth of the explanation in the cases where this phenomenon is observed. In other cases no doubt the pressure of growth on veins is a minor factor in aggravating the œdema.

If venous obstruction is a consequence of "dropsical arm," or at most a minor factor in aggravating it, some other explanation of the dropsy must be sought. In point of fact, the onset of a dropsical arm is determined by the blocking, not merely of the main lymphatic trunks, but also of all the collateral routes about the shoulder by which the lymph could find a passage. The pathology of brawny arm is a corollary to the permeation theory. As I have shown, permeation spreads from the breast in an ever-widening circle, which must ultimately envelop the shoulder completely. I have demonstrated the growing edge of permeation in the deltoid region. Perilymphatic fibrosis converts all the permeated lymphatics, small and large, into cords of fibrous tissue, and the arm is entirely cut off from the lymphatic circulation by the destruction of the lymphatic channels, principal and collateral. Thus, as might be expected, the dropsical arm of breast cancer is not met with until the disease has reached a very advanced stage. Often within a few months of its appearance obstruction to the pleural lymphatics shows itself by the

appearance of pleural effusion. What is the factor which determines the collection of serous fluid on the pleura of the affected side? It is the choking-up of the subpleural lymphatic plexus by permeation, or its obliteration by consequent perilymphatic fibrosis. Of the former process I am able to show you an excellent photograph. Some time after the arm has been cut off from the lymph circulation the process of permeation, at the opposite side of its circle of extension, reaches the pleura, and though repeated tapping may give temporary relief, death is certain within a few months at most. Thus in a majority of chronic cancers which produce brawny arm death is due to internal lymphatic obstruction—a lethal factor the importance of which seems hitherto to have escaped recognition. On two occasions Mr. A. G. R. Foulerton has examined lymph for me from cases of dropsical arm, and in both instances has found it sterile.

ORIGIN OF THE OPERATION OF LYMPHANGIOPLASTY.

Until two years ago the only treatment available for cases of dropsical arm, after elevation had ceased to produce any effect, was either amputation of the arm or the use of morphine. The readiness of patients to listen to the suggestion of amputation is the best possible proof of the intolerable agony caused by the disease. Two years ago I was asked to amputate a dropsical arm, the patient's consent to the operation having been obtained. At this time my work in the Cancer Research Laboratories of the Middlesex Hospital had taught me that the condition would be cured if the swollen limb could be provided with a new set of lymphatic vessels. And I bethought me of a section in my possession showing a silk ligature which had been embedded in the tissues for ten years. Though superficially eroded the main substance of the thread is intact. Moreover, the interspaces between the silk fibrils are so small that no intrusive cells have been able to enter and obstruct them. The section, moreover, affords no evidence of any clotting of the tissue fluids in the interspaces of the thread. These facts pointed to a silk thread as affording for the tissue fluid a permanent conduit, sufficiently unabsorbable, and not liable to obstruction by organisation or thrombosis. I accordingly buried a number of silk threads in the subcutaneous tissues of the arm, and permanently relieved the pain and swelling during the remainder of the patient's life. I mention these facts to show that the operation of lymphangioplasty was not a casual happy thought, but the end-product of a long course of laboratory work, which seemed at the time to have no practical application to the treatment of lymphatic obstruction.

BENEFITS TO BE EXPECTED FROM LYMPHANGIOPLASTY.

Before describing the operation I wish to state clearly that it is a palliative only and that it has no claims to prolong life or to modify the natural downward course of the disease. In favourable cases it has the following effects: (*a*) Complete relief from pain within 24 hours, unless the pain is partially due to some cause, such as nerve pressure, independent of the œdema. (*b*) A marked and rapid fall in the tissue tension of the whole area drained by the threads. The arm in consequence, instead of being hard and brawny, becomes abnormally soft and flabby. This may sometimes occur even though postural treatment is neglected and in the absence of any marked diminution of the diameters of the arm. (*c*) Rapid subsidence of the swelling, commencing immediately in the hand and extending to the forearm within 24 hours. At first the upper arm is unaffected, or its diameters may even slightly increase. But within a week or two the diameters of the upper arm are also markedly lessened. The subsidence is usually permanent, unless and until pleural effusion supervenes to interfere with drainage. These effects are at first dependent upon the adoption of proper postural after-treatment, but after a few months elevation of the arm may be entirely abandoned without any marked increase of swelling. (*d*) Return of power to the paralysed arm if the paralysis is of recent date. If the paralysis is of more than a few months' standing, no return of power is to be expected. (*e*) An improvement in the general condition, dependent partly upon relief from pain and its associated symptoms of insomnia and depression, and partly upon the abandonment of sedatives.

TECHNIQUE OF LYMPHANGIOPLASTY FOR BRAWNY ARM.

The special materials necessary are a set of suitable probes, lymphangioplasty forceps, with jaws specially designed to take a firm grip of either end of the probe; and a supply of No. 12 tubular twisted silk. These requisites may be obtained from Messrs. Mayer and Meltzer. The tissues of the arm are drained by two long U-shaped lines of silk, each line composed of two threads of No. 12 tubular twisted silk. One of these lines drains the front of the arm, the other the back. The bend of each U lies immediately above the wrist, and its two limbs occupy respectively the radial and ulnar side of the limb. Thus, along the whole length of the limb, are found four double lines of silk, spaced out round the limb as nearly as possible at quadrant intervals.

The principal difficulties of the operation are connected with the maintenance of the silk in an aseptic condition. Owing to the large area dealt with, extending on to the back, the necessary changes in the posture of the arm, and the length of the silk threads, accidental contact may very easily occur between the silk and the surface of the skin, the edges of the incisions or surrounding objects. I regard the use of masks as essential, and the silk ends not actually dealt with at the moment must be kept wrapped in sterile gauze, which is also useful to protect them from the edges of the incisions as they are being drawn in after the probe.

I will now lay before you my clinical experience of the operation in a series of 15 cases, analysed into five classes:—

A. CASES IN WHICH A DROPSICAL ARM IS THE ONLY MANIFESTATION OF ACTIVE DISEASE.

Three of the cases in my series may be regarded as ideal ones for the operation of lymphangioplasty. Each of these had a long history of cancer, the disease having begun respectively 14, 14, and 7 years previously. Evidently, the defensive processes of fibrosis were exceptionally active. In each of these cases no clinically discoverable mass of cancer existed at the time of the operation, and no ulceration was present as a menace to operative asepsis. Under these conditions the operation appears to be uniformly successful. In all these cases pain and swelling were relieved within a day or two of the operation. One of them remained free from pain and swelling to the day of her death (Case 1); a second survives 21 months after the operation without recurrence of the swelling (Case 5), but still suffers occasional attacks of pain, due to a palpable axillary recurrence which has now appeared. In the third case (Case 8), after complete relief lasting about four months, pleural effusion showed itself, and pain and swelling in some degree recurred in the arm, owing to consequent impaired lymph circulation in the thorax. The pain, however, was slight, and though morphine had been habitually used prior to the operation, it remained unnecessary until the patient's death from pleural effusion and thoracic growth.

B. CASES IN WHICH RECURRENT MASSES OF GROWTH ARE PRESENT, BUT ULCERATION AND PLEURAL EFFUSION ARE ABSENT.

Six of my cases come under this heading. In all of these cases recurrent masses of growth were present in the neighbourhood of the brachial plexus. Three of these were successful; in one the period of benefit was very short, and two were failures. In this class of case the difficulty is to decide how much of the pain is due to nerve pressure and how much to the dropsical arm. Evidently, in view of the successful cases, the mere presence of growth in the axilla or supraclavicular region is not a bar to operation, but the relief obtained may not be complete, and in half the cases no benefit results. My experience teaches that if the pain is referred mainly to the axilla or supraclavicular region, or if it is a lancinating pain shooting down the arm, little or no benefit is to be expected from lymphangioplasty. If, on the contrary, the pain is a heavy diffuse pain referred to the whole limb, or if it is located in the elbow or the hand, the operation will afford relief, even though there is recurrence above or below the clavicle.

C. CASES IN WHICH AXILLARY OR THORACIC ULCERATION IS PRESENT AND PLEURAL EFFUSION IS ABSENT.

This is a class of case which I approached with caution and with some reluctance, for I feared that in the presence of a cancerous ulcer upon the thorax or in the axilla, it would be very difficult to prevent contamination of the silk threads. The first case (Case 7) upon which I operated in the presence of ulcerated growth was submitted for a month previously to ionic medication with mercury in order

to cleanse the ulcers. In two later cases antiseptic irrigation or applications of acetone have been employed. Thanks to the loyal coöperation of medical and nursing colleagues in these and other precautionary measures, the calamity of suppuration has never occurred. In every case all the incisions have healed by primary union, nor has it been ever necessary in any of the cases under this heading to remove the threads. Repeated success in these cases has increased my boldness in dealing with them. In my latest case (Case 15) the axilla was a gaping chasm pouring out pus, and the ulceration had completely surrounded the arm save for a bridge of normal tissue posteriorly, about 6 inches wide, which afforded the only possible avenue for the threads. In this case, primary union of the incisions occurred, and the patient is delighted with the relief of pain and swelling, and the return of muscular power which have resulted from the operation. Mr. A. O. English acted as house surgeon, and the case was nursed in Stafford Ward, one of the cancer wards of the Middlesex Hospital.

The onset of acute eczema of the arm three weeks after operation in one of the cases is a complication unique in my experience, and may fairly be regarded as an unfortunate accident which spoiled a case giving every promise of success. I may remind you that when physiologists wish to increase the production of lymph in a limb, the method they adopt is to scald the skin of the anæsthetised animal. It is easy to believe that acute eczema would have a similar effect. The other two cases in this class were unequivocal successes. It may, I think, be concluded that the presence of ulceration does not appreciably increase the risk of lymphangioplasty, provided means are taken to clean the ulcers and to shut them off effectually from the field of operation. With my present experience I should not hesitate to operate upon cases presenting thoracic ulceration.

D. Cases in which Pleural Fluid or other Evidence of Thoracic Cancer is Present, but the Condition of the Patient does not Negative a General Anæsthetic.

When pleural fluid is present the balance of life remaining to the patient is in any case likely to be a short one. Thus in one case the chest only filled up two days before death, and 70 ounces of fluid were present in the pleura on the affected side. This is an extreme case. As a rule pleural effusion precedes death by two or three months, occasionally perhaps by a year. Apart from this question of survival the success of the operation is doubtful, for hydrothorax shows that the lymphatic block extends over a wide area including the pleura. Under such conditions nothing can be promised, but if paracentesis is also done a few weeks' relief may be obtained, and therefore an urgent desire on the patient's part for a brief respite from pain may justify an operation. The necessity of morphine—a drug to whioh many people have a kind of conscientious objection—may thus be postponed for a while.

E. Cases in which the Patient is so Ill that the Risk of a General Anæsthetic cannot be Faced, or in which the Silk Threads must be Led through Cancerous Tissue.

These cases are quite unsuitable for lymphangioplasty, a fact which I learned by experience in one of my earliest cases.

Mortality of Lymphangioplasty for Breast Cancer.

The case to which I have just referred is the only one of my series in which primary union has failed, and the only one in which death has followed closely upon the operation. Including this unsuitable case, the operation mortality of my series is 7 per cent.; excluding it the operation mortality is *nil*. I think an impartial critic will agree that the latter is the fairer estimate, and that my cases show the procedure to be almost free from risk to life when asepsis is maintained. The operation is indeed equivalent merely to a 5-inch skin incision, that being about the aggregate length of the multiple small incisions. Shock and hæmorrhage need not be feared.

The Choice of Cases for Lymphangioplasty.

The preceding analysis of my cases shows that lymphangioplasty is contra-indicated in cases where a general anæsthetic cannot be borne, and in cases where the silk threads would have to pass through cancerous tissue. It is also inadvisable to operate where there is growth present about the shoulder, if the pain is mainly an axillary one, or is a lancinating pain shooting down the arm. In the presence of pleural effusion or thoracic secondary growths the benefits of the operation are transient, but the shortest period of relief may, under the circumstances, be considered by the patient as worth having.

Minor Degrees of Swelling.

Minor degrees of obstruction to the return of lymph from the arm are not infrequently met with in breast cancer. The operation of lymphangioplasty should not be applied indiscriminately but should be reserved for the severer degrees of lymph stasis in which other modes of treatment are powerless. The axillary scarring which necessarily follows removal of glands may sometimes lead to persistent œdema of the arm, usually slight in amount. In such cases the application of a bandage and the elevation of the arm on an inclined plane for one or two hours a day will usually suffice. But in true brawny arm, even in favourable cases, where the affection has not reached the stage of brawny hardness, the effects of posture are temporary and imperfect. If the œdema is marked and progressive, and if postural treatment is painful or ceases to be effective, the stage of brawny hardness should be anticipated and prevented by the performance of lymphangioplasty. The only objection to this course is that the patient will underestimate the benefits she has derived from the operation, for prophylaxis is less striking than cure and earns less gratitude.

Erysipelas as a Cause of Lymphatic Œdema.

Lymphatic œdema sometimes, though rarely, supervenes on erysipelas in situations where the subcutaneous tissues are loose and easily distended by serous fluid. Its most common situation is the eyelids, though it may affect more or less the whole of the face. In such cases it is easy to imagine, though impossible to prove, that the lymphatic vessels of the part have been obliterated by an unusually severe lymphangitis which has swept through them like a prairie fire, leaving only fibrous cords to represent the vessels. No satisfactory treatment has hitherto existed for lymphatic œdema of the eyelids following erysipelas, and I was very anxious for an opportunity to try the effect of lymphangioplasty in such a case. In the absence of a suitable case I have been unable to try this method of operation. Priority in the application of lymphangioplasty to this class of case belongs to Mr. A. B. Mitchell of Belfast, who has recorded two successful cases. I am much indebted to Mr. Mitchell for supplying this conclusive evidence of the value of lymphangioplasty in post-erysipelatous œdema. These cases supply an additional proof, if one were needed, that the effects of lymphangioplasty in the limbs are not primarily due to the elevation which forms a necessary part of the after-treatment. The eyelids tend to drain by gravity either into the face or the scalp, whether the patient be standing or lying. Yet until the operation in each of Mr. Mitchell's cases the œdema had persisted unchanged for about two years.

The South Kensington Science Museum.—The President of the Board of Education has appointed a Departmental Committee to consider and report upon various questions in regard to the present condition and the future development of the valuable collections comprised in the Board's Science Museum at South Kensington and Geological Museum in Jermyn-street. In particular the committee are asked to advise him (*a*) as to the precise educational and other purposes which the collections can best serve in the national interests; (*b*) as to the lines on which the collections should be arranged and developed, and possibly modified, so as more effectively to fulfil these purposes; and (*c*) as to the special characteristics which should be possessed by the new buildings which it is hoped will shortly be erected on the South Kensington site to house these collections, so as to enable the latter to be classified and exhibited in the manner most fitted to accomplish the purposes they are intended to fulfil. The committee consists of Sir Hugh Bell, Bart., D.C.L. (chairman), J. J. Dobbie, F.R.S., LL.D., Sir Archibald Geikie, K.C.B., F.R.S., R. T. Glazebrook, D.Sc., F.R.S., Andrew Laing, M.I.C.E., the Hon. Sir Schomberg McDonnell, K.C.B., C.V.O., Sir William Ramsay, K.C.B., F.R.S., LL.D., Professor W. Ripper, D.Eng., M.I.C.E., Hon.M.I.Min.E., Sir W. H. White, K.C.B., F.R.S., LL.D., with Mr. F. G. Ogilvie, C.B., one of the secretaries of the Board of Education, as secretary.

The Goulstonian Lectures

ON

A CONTRIBUTION TO THE LOCALISATION OF CEREBRAL FUNCTION, BASED ON THE CLINICO-PATHOLOGICAL STUDY OF MENTAL DISEASE.

Delivered before the Royal College of Physicians of London on March 1st, 3rd, and 8th, 1910,

BY JOSEPH SHAW BOLTON, M.D. LOND., F.R.C.P. LOND.,

FELLOW OF UNIVERSITY COLLEGE, LONDON; SENIOR ASSISTANT MEDICAL OFFICER, LANCASTER COUNTY ASYLUM, RAINHILL, ETC.

LECTURE II.[1]

Delivered on March 3rd.

MR. PRESIDENT AND GENTLEMEN,—Before proceeding to the consideration of the results of my investigation of the cortex cerebri of certain selected cases of insanity I propose to refer briefly, from the clinico-pathological aspect, to certain abnormal and morbid appearances which are exhibited by the intracranial contents of the subjects of mental disease.

ABNORMAL AND MORBID APPEARANCES OF INTRACRANIAL CONTENTS IN MENTAL DISEASE.

With few exceptions, which are unimportant in this connexion, such abnormal and morbid appearances have long been well known, but, at any rate up to the time when I published my first paper on the subject, no attempt had been made to correlate these with any special symptomatology, and they had been described as common concomitants of the more chronic forms of insanity. Of these abnormal and morbid appearances, the more important are abnormal structure or wasting of the cerebrum, thickening and opacity of the pia-arachnoid, disease of the cerebral vessels, excess of intracranial fluid, subdural deposit, thickening of the dura mater, and abnormalities of the cranial vault. In two consecutive series of 200 and 233 cases of mental disease, from which cases of general paralysis and special examples of gross lesion, &c., were excluded, and in which both the clinical and the post-mortem aspects presented by these were systematically recorded, I was able to determine that an important correlation existed between these.

The cases of the first series were divided pathologically into five convenient though artificial groups—namely: (1) cases with or without abnormal but without morbid appearances; (2) cases with slight morbid appearances—namely, slight excess of intracranial fluid, slight thickening of the pia-arachnoid, which stripped rather more readily than natural, and slight or no cerebral wasting; (3) cases with morbid appearances of moderate grade—namely, intracranial fluid to the level of the tentorium, moderate thickening of the pia-arachnoid which stripped readily from the hemispheres, and a moderate degree of cerebral wasting; (4) cases with marked morbid appearances—namely, intracranial fluid well above the tentorium, much thickening and opacity of the pia-arachnoid which stripped very readily from the cerebrum, much wasting of the cerebrum, and, as a rule, marked disease of the cerebral vessels; and (5) cases with gross morbid appearances—namely, very marked excess of intracranial fluid, marked thickening and opacity of the pia-arachnoid which stripped like a glove from the hemispheres, gross wasting of the cerebrum, and almost invariable affection of the cerebral vessels which were usually markedly diseased.

On comparing the cases, from the aspect of symptomatology, with the post-mortem records, it was at once evident that these five groups corresponded, with few readily explicable exceptions, with five artificial clinical groups—namely: (I.) cases without dementia; (II.) cases with appreciable dementia; (III.) cases with dementia of moderate grade, i.e., the ordinary chronic lunatic with moderate dementia; (IV.) cases of severe dementia; and (V.) cases of gross dementia.

[1] Lecture I. was published in THE LANCET of April 2nd, 1910, p. 905.

Exactly similar results followed the study of the second and confirmatory series of cases; and I have since for some years been accustomed to prognose with certainty intracranial appearances in all but the rare cases in which I have been uncertain as to the clinical state of the patient.

AMENTIA AND DEMENTIA.

For reasons which I shall very briefly lay before you I was hence able to subdivide cases of mental disease into two types—namely: (1) cases which from the macroscopic post-mortem aspect exhibited abnormal, no abnormal, no morbid, or slight morbid appearances, and (2) cases which exhibited morbid appearances of any grade of severity and in some instances abnormal appearances also. The former group from the clinical aspect I class under the term "amentia," which I employ to connote *the mental condition of patients suffering from deficient neuronic development;* and the latter under the term "dementia," which I use to signify *the mental condition of patients who suffer from a permanent psychic disability due to neuronic degeneration following insufficient durability.*

The subjects of amentia, therefore, as I shall suggest from the macroscopic and prove from the microscopic aspect, suffer from a more or less marked grade of subevolution of the cerebrum. The chief clinical varieties of amentia are low grade amentia, or idiocy and imbecility with or without epilepsy, and high grade amentia, which includes "moral," unstable, and excited cases, together with cranks and asylum curiosities, recurrent cases of all types, hysteria, epileptic insanity, and true paranoia and allied cases.

Before referring to the question of dementia, a further explanatory description of this mental condition is necessary. The word "dementia," and particularly the word "demented," are employed by alienists for different purposes. Some speak of demented patients recovering, others regard almost any reasonably quiet chronic case as demented, and others, again, deny the possibility of in any way whatever correlating psychic states and material conditions of the brain, and regard such as a form of confusion of thought. It is therefore necessary, in addition to defining the term, to indicate the commoner symptoms which are presented by patients suffering from dementia. These, in brief, are as follows:—General dulness and apathy, a loss of initiative, and an indifference to their surroundings; a marked degree of stereotypism of all the mental processes, and an inability to learn new acquirements; a mechanical method of performance of known acquirements, a general stupidity and inability to understand when an attempt is made at correction of any kind, and a tendency to revert to accustomed modes of speech and action; finally, there is a tendency to the repetition of accustomed action which often shows that these have been performed in the entire absence of intelligent volition. This description, I may remark, in certain respects resembles that given by numerous experimental physiologists with regard to the motor exhibitions presented by certain lower vertebrates after removal of the cerebral hemispheres, and by certain higher mammals after removal of the frontal lobes.

The subjects of dementia, as I shall indicate both macroscopically and microscopically, suffer from a more or less marked grade of involution or dissolution of the cerebrum. I group such cases into a primarily neuronic class of senile, presenile, mature, and premature types; into a progressive and secondary class, which includes senile dementia associated with gross degeneration of the cerebral vessels, and, as the result of a special study, general paralysis also; and into a class of special varieties following sense deprivation, epilepsy, and cerebral lesions.

This generalisation of amentia and dementia is a gross one, and, as I shall indicate shortly, is based on the fact that cases of mental disease exhibit a lesion of the cortex of the prefrontal region of the cerebrum, which lesion, in the case of amentia, is of the nature of a true subevolution, and, in the case of dementia, is of the nature of a true involution or dissolution.

I would remark that the existence of amentia does not preclude the onset of dementia, that the necessary precursor of dementia is a more or less severe grade of mental confusion, and that mental confusion, when incited by temporary and removeable causes—e.g., alcoholic excess—is often entirely recovered from. Further, certain clinical indications are frequently, though not constantly, present which

enable a prognosis to be made as to whether a given case of mental confusion is recoverable or will result in dementia. Again, it is certain that recoverable mental confusion may occur in persons possessing normal cerebra. Lastly, mental confusion, followed by dementia, more commonly occurs in cases with cerebra of normal or relatively normal development, though probably of deficient neuronic durability, than in cases with cerebra which exhibit some grade of subevolution. The generalisation may, in fact, be made that the greater the grade of amentia the less is the tendency to dementia, not through a more normal durability of the cortical neurons of the former, but owing to the fact that cases of amentia so readily suffer from symptoms of mental alienation under any form of "stress" that, as a rule, little or no irreparable damage to the cortical neurons results.

The generalisation of amentia and dementia, I may remark, does not cover the subject of special symptomatology, which, as I hope to indicate but not yet to fully prove, depends on the degree of evolution of the cortex of the projection areas and zones of lower association of the cerebrum.

Of the abnormal and morbid intracranial appearances to which I am about to refer, the simplest, and that which is most readily determinable with accuracy, is the weight of the stripped cerebral hemispheres in the fresh state. In the following table are classified under the five groups which I have indicated the weights of the stripped hemispheres from 417 consecutive and unselected cases of mental disease.

Weights of Stripped Hemispheres from 417 Cases.

Group.	Total number of cases and condition.	Males.		Females.	
		Number of cases.	Average weight in grammes.	Number of cases.	Average weight in grammes.
		Normal.	589	Normal.	534
I.	61. No wasting	21	552	40	497
II.	95. No, or slight wasting	21	564	74	485
III.	96. Moderate wasting	31	560	65	482
IV.	90. Marked wasting...	38	511	52	456
V.	75. Gross wasting ...	25	513	50	437

It is at once evident that the weights in all the groups are much below the average normal weight, which I have estimated from the recent statistics of Marchand. I do not lay stress on this point as Marchand's results were obtained from the brains of Hessians, although if to the weights of Group III. one added the 30 to 50 grammes which it is probable they have lost in consequence of wasting they would come approximately up to Marchand's figures. I would, however, indicate the obvious and important conclusion that the average weights of the hemispheres in Group III. must before wasting had occurred have been considerably greater than those in Groups I. and II. The average weights of the hemispheres of Groups IV. and V., in which severe and gross wasting had occurred, point to the same conclusion—namely, that the original weights in these groups must have been considerably greater than those in Groups I. and II., since the loss of cerebral tissue in the former groups cannot average less than about 100 grammes and may be much more, in view of the large amount of intracranial fluid which is present. The striking conclusion thus follows that the average brain weight of lunatics without intracranial morbid appearances is less than the original average brain weight of lunatics who exhibit these. In other words, the cerebra of Groups III., IV., and V. have fallen from a higher original level of development than that to which those of Groups I. and II. have attained.

[Certain abnormal and morbid appearances were then referred to, and the regions of wasting in dementia were described as follows:—(1) The greatest amount occurs in the prefrontal region. (2) The wasting is next most marked in the remainder of the first and second frontal convolutions. (In dementia paralytica Broca's gyrus should, as a rule, be included here, and (2) and (3) should follow (4).) (3) It is perhaps next most marked in the ascending frontal and Broca's gyri, though this grade should, in many cases at least, follow (4). (4) It is next most marked in the first temporal gyrus and the insula, and in the superior and inferior parietal lobules. In practically all cases it is more marked in the two former than in the two latter. (5) It is least marked in the remainder of the cerebrum (including the orbital surface of the frontal lobes), particularly the inferio-internal aspect of the temporo-sphenoidal lobe and the posterior pole of the hemisphere.]

I am of the opinion that exceptions to this general order are invariably due to vascular or traumatic causes, and should therefore be excluded from the ordinary and normal wastings of dementia.

I will now show a number of hemispheres in illustration of the abnormal and morbid appearances which I have indicated. They are chosen on clinical grounds, being from cases in which I was interested and with the mental condition of which I was very familiar. [Of these illustrations the following three are selected, and are shown in Figs. 11, 12, and 13.]

Fig. 11 illustrates a large brain of rather simple pattern and without morbid intracranial appearances. The case showed no dementia. Figs. 12 and 13 respectively show cerebral wasting of moderate and severe grades (Groups III. and V.). The first of these exhibited a moderate degree and the second a severe degree of dementia.

[The conditions influencing the passage of cases from Group I. to Group III. were then indicated, and the influence of degeneration of the cerebral arteries in causing still further cerebral dissolution with passage into Group IV. and Group V. was referred to and summarised as follows:—*In a cerebrum which has begun to break down, or where degeneration has progressed to the "moderate" stage (Group III.), the presence of incidence of gross degeneration of the cerebral vessels will cause rapid progress of the neuronic degeneration, with, from the clinical aspect, gross dementia.*]

MICROMETRIC EXAMINATION OF THE CEREBRAL CORTEX IN MENTAL DISEASE.

I now turn to the second part of my subject—namely, the description of the results of the micrometric examination of the cerebral cortex. The series I am about to describe includes 30 cases, of which 4 are normals, and 26 are types of mental disease, which grade from the idiot on the one side to the gross dement and gross general paralytic on the other. In 12 cases the visuo-sensory and visuo-psychic regions, and in 17 cases the prefrontal, have been examined and measured, whilst in one, to which I shall refer in greater detail, all these regions have been exhaustively dealt with. From the theoretical aspect a series of cases in which all three regions had been studied would have been preferable. This, however, has not been possible, owing to the length of time occupied by the collection and examination of the material, and the great labour and particularly the eyestrain necessitated by such a method as that which I have been compelled to adopt. The micrometric study of the cortex by this method produces, however, such trustworthy and comparable results that the larger number of cases which I have thus been able to examine has widened the scope of the research without impairing the validity of the conclusions which result.

[Photographs of normal cortex and of cortices of cases of amentia and dementia were then exhibited.]

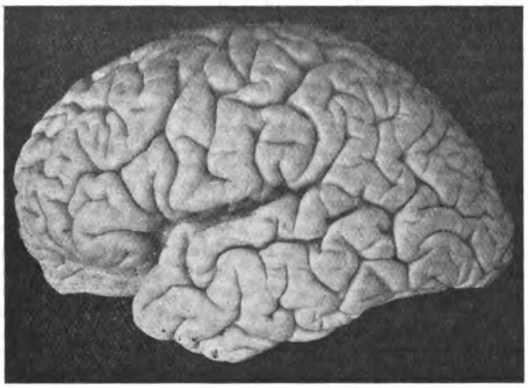
The final plate of this series (Fig. 14) shows the approximate depth of the cortex in a fœtus of six months, a stillborn infant, a case of severe amentia, a normal adult, and a case of severe dementia. Lines are drawn which include the second, and the third to the fifth laminæ, in order to show these more clearly.

I now come to the description of the results of the micrometric measurement of the cortex. I do not propose to describe the cases in detail or to trouble you with actual figures, as I have already dealt in detail with the method which I have adopted for the production of the general average measurements. I have therefore prepared the series of cases in percentages of the normal. I would remark that each case in itself represents the results of a small research, as the difficulties which have to be overcome in the preparation of vertical sections, which include a sufficient number of measurable regions, are considerable even before it is possible to begin the measurements. In several instances it has in fact been necessary to reject a likely case owing to

the impossibility of obtaining these, for in some cases either every block which one cuts turns out to be more or less oblique, or else some particular region, especially the flat surface or the bottom, is either oblique or missing. I may add that several cases, when ready for measurement, have required rejection owing to the existence of cerebral œdema.

On the plate (Fig. 15) are shown the general average measurements of 30 cases, grouped under visuo-sensory, visuo-psychic, and prefrontal regions. The cases are numbered to allow of identification, and those placed in the visuo-sensory and the visuo-psychic groups are the same. The cases included in each group are arranged on each side of the normals, those of amentia rising in order of mental capacity from the left-hand side, and those of dementia falling in order of grade of dementia on the right side. The visuo-sensory group includes one idiot, two imbeciles, a case of imbecility with premature dementia, two cases of recent acute insanity, and a case of simple acute mania of nine months' duration on the left-hand side of No. 8, the normal, and a case of epileptic dementia, two cases of blindness with dementia, a case of premature dementia, and a case of well-marked dementia on the right-hand side. The visuo-psychic group contains the same cases. The prefrontal group includes 5 cases of imbecility of different grades from severe to mild, 3 cases of recurrent and chronic insanity without dementia, 3 normal cases (the central one of which, No. 23, is taken as the basis for percentages), a case of imbecility with dementia, 2 cases of dementia of moderate grade, 1 case of well-marked dementia (No. 13, which is already included in the other groups), 2 cases of gross dementia, and 1 case of gross dementia paralytica.

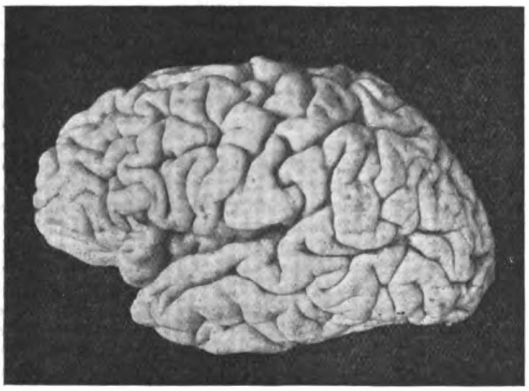
In the visuo-sensory region the laminæ indicated are from above down the first or superficial layer, the second or layer of pyramidal cells, the third or granule layer, which is in this region duplicated, and contains in its midst the line of Gennari, the fourth or inner line of Baillarger, and the fifth or layer of polymorphic cells. It is unnecessary at present to do more than draw your attention to the markedly decreased depth of the line of Gennari in the two blind cases, Nos. 10 and 11, which detail proves that the region under consideration is the projection area for visual sensations.



In the case of the visuo-psychic and prefrontal regions the laminæ indicated are from above downwards, the first or superficial, the second or pyramidal, the third or granule, the fourth or inner line of Baillarger, and the fifth or polymorphic.

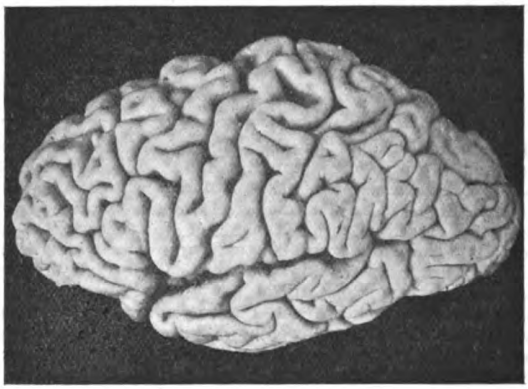
In the case of the gross dements, Nos. 28 to 30, in the prefrontal region, I would indicate that the depth of the outer two laminæ as measured is not an accurate criterion of the actual loss of neurons, owing to the proliferation of the non-neuronic elements which, especially in No. 30, is so marked as to a considerable extent to neutralise the results of neuronic destruction.

It is, of course, impossible to indicate the general conclusions which result from the study of these measurements without dealing with the cell layers individually. The most important result is, however, perhaps sufficiently evident to be worth pointing out.



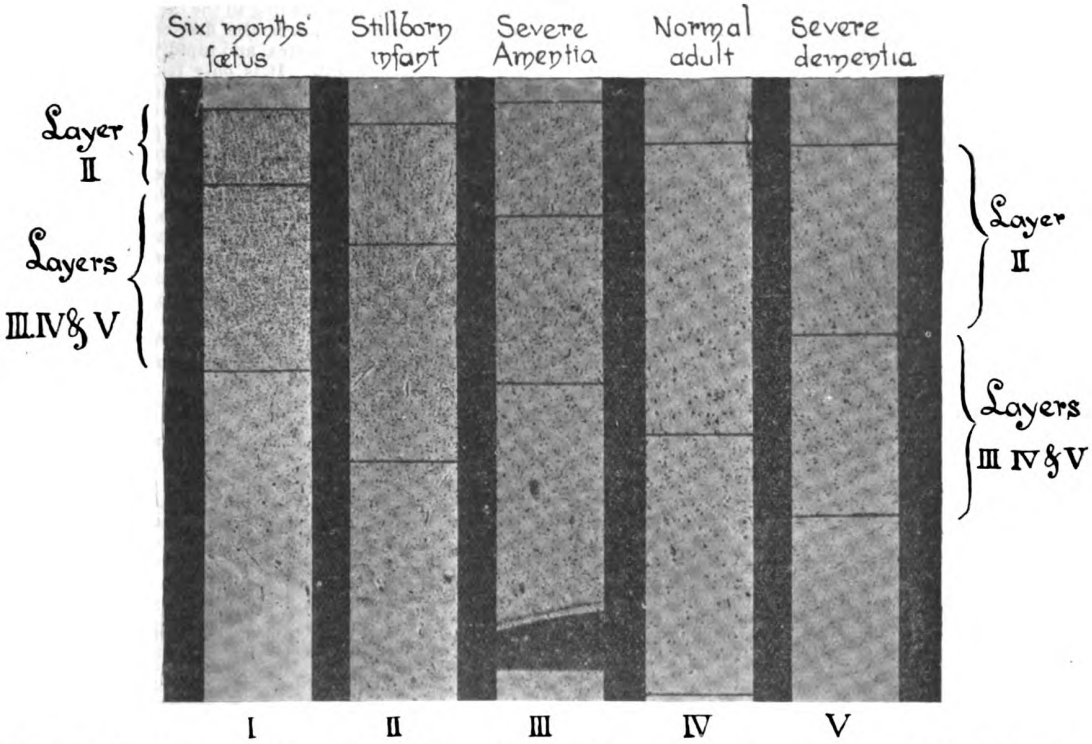
Taking the prefrontal region first, it is obvious that in this region a definite relationship exists between the depth of the cortex of the respective cases and the degree of amentia or dementia which existed. On the other hand, no such relationship exists in the case of the visuo-sensory and visuo-psychic regions, but an equally important conclusion may be drawn—namely, that great individual differences in depth are evident, in the former even more than in the latter, and that these individual differences not only bear no relationship to the degree of amentia or dementia which existed, but even in the case of the two regions differ in individual cases. The

FIG. 11.



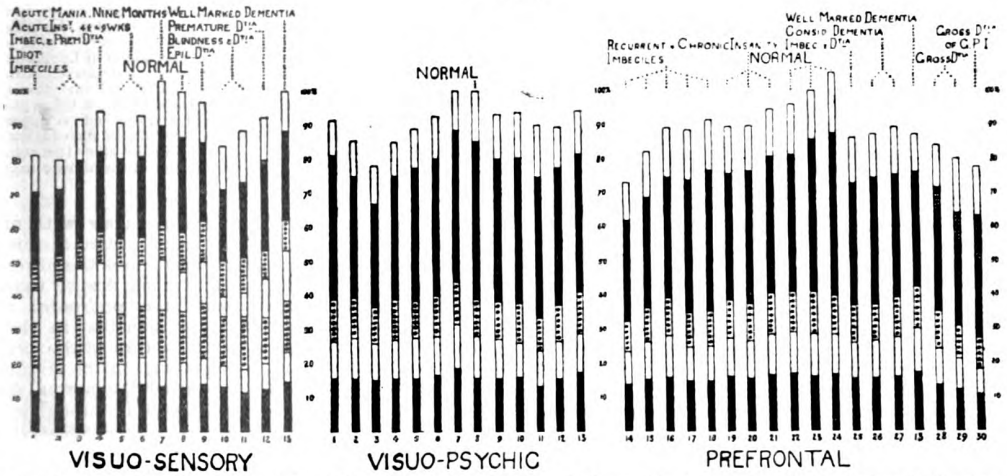
A female, aged 35 years, single. A drunken prostitute with over 50 convictions. Excitable, unstable, cunning, and very dangerous. A terror to the nurses owing to her violence and her unfounded accusations of ill-treatment. Cerebrum large and of rather simple pattern. Left hemisphere 618 grammes. No wasting.

FIG. 12.



A male, aged 41 years, single, seaman. Duration of attack nearly 15 years. A case of chronic insanity who was at first depressed and confused. He then exhibited ideas of persecution, became grandiose, and eventually developed a moderate grade of dementia. Until he became demented he never spoke, refusing to communicate with others except by signs or by writing. Left hemisphere 525 grammes. Considerable wasting, chiefly in the prefrontal region. Several small softenings in the left hemisphere (cf. mental condition). Slight atheroma of the cerebral arteries.

FIG. 13.

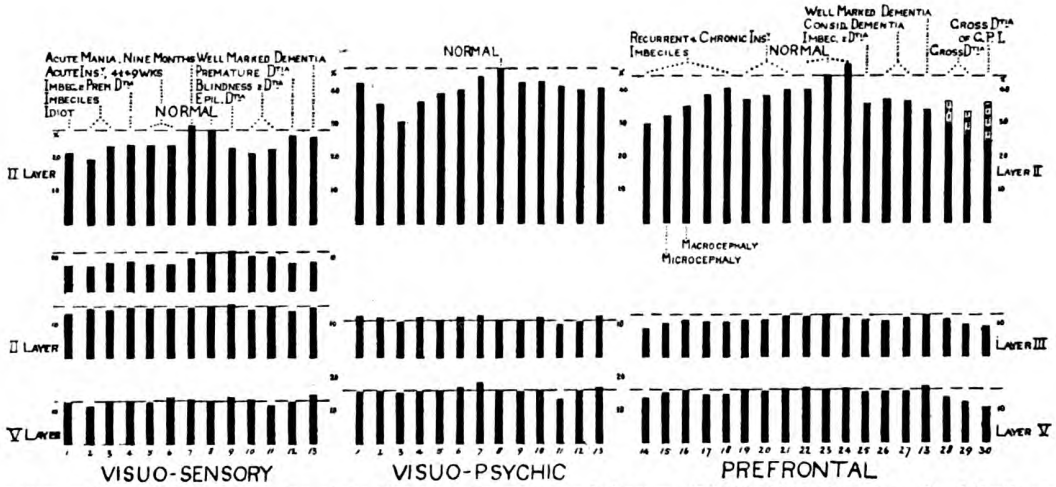


A female, aged 78 years, widow, housekeeper. Duration about three years. A case of marked senile confusion. She was lost to time and place, and restless. She undressed herself. She suffered from illusions of identity. She developed gross dementia. The cerebrum had originally been probably of above the average size. Left hemisphere 480 grammes. Gross cerebral wasting, which is especially marked in the prefrontal region. Some degree of asymmetry, the right hemisphere being of simpler pattern than the left. Gross degeneration of the cerebral arteries.

FIG. 14.

40 diameters. The development of the prefrontal cortex and its condition in amentia and dementia. Horizontal lines are drawn to indicate Lamina II., the pyramidal or associative lamina, and the combined III., IV., and V. laminæ. A comparison of columns I., II., and IV. indicates the relatively late development, and also the high degree of normal evolution of Lamina II. compared with Laminæ III., IV., and V. Column III. indicates the marked subevolution of the cortex which exists in severe amentia, and Column V. the marked dissolution of the cortex which occurs in severe dementia.

FIG. 15.



The general average depths, in percentages of the normal, of the cortices of 30 cases of various types. In the three series the cases are grouped on each side of the normals according to the grade of amentia and dementia. The numbers at the bottom of the columns indicate the several cases. The subdivisions of the columns from above downwards indicate the five laminæ of the cortex—namely, the outer fibre or superficial, the outer cell or pyramidal, the middle cell or granule, the inner fibre or inner line of Baillarger, and the inner cell or polymorphic. In the case of the visuo-sensory area, the receptive lamina consists of two layers of granules separated by an intermediate fibre layer, the line of Gennari, in which terminate the optic radiations, and which is much decreased in depth in Nos. 10 and 11, the two blind cases. The figure shows that, whereas in the prefrontal region the cortex varies in depth according to the degree of amentia and dementia, no such variation occurs in the case of the visuo-sensory and visuo-psychic regions. The further conclusions which are derived from a study of the individual cell layers are indicated in Fig. 16.

latter point is sufficiently evident if the first three cases are compared, since No. 1, an idiot, has poor visuo-sensory but good visuo-psychic measurements; No. 2, a well-marked imbecile, has equally poor visuo-sensory as, but rather worse visuo-psychic measurements than, No. 1; whilst No. 3, a moderate imbecile, shows fairly good visuo-sensory measurements but visuo-psychic which are much below those of either No. 1 or No. 2.

As the visuo-sensory region subserves the reception and the immediate transformation of visual sensations, and the visuo-psychic, as I indicated in the last lecture, is concerned with associational functions which have a special visual hall-mark, it may be concluded from these measurements that marked individual differences exist with regard to both these capabilities in the case of different subjects. The measurements thus afford anatomical proof of a clinical truth, which is, I think, generally recognised, in spite of the difficulty which attends its satisfactory exhibition.

In view of the possible criticism that the ages of the patients might to some extent explain the differences in measurement I would remark that these vary from 11 to 78 years, and that I have endeavoured, without success, to trace even a possible suggestion of any relationship between age and measurement.

FIG. 16.

The outer, middle, and inner cell laminæ of the 30 cases indicated in the last figure. (I.) The visuo-sensory area. Specialisation is marked, and is shown by the greatly increased depth and complexity of L.III., the middle cell or receptive lamina, and by the much decreased depth of L.II., the associative lamina, and the decreased depth of L.V., the instinctive lamina. Well-marked individual variation occurs in the cases of the outer cell or pyramidal lamina and the outer of the two granule layers. In this region the cortex does not vary in depth according to the degree of amentia and dementia. (II.) The visuo-psychic region. Specialisation is not marked but is indicated by the well-developed III. or granule lamina, and also by certain facts of evolution mentioned in Lecture II. Individual variation is well-marked in the case of the outer cell or pyramidal lamina. The cortex does not vary in depth according to the degree of amentia and dementia. (III.) The prefrontal region. Indications of specialisation and individual variation are practically absent. All the cell layers vary in depth according to the degree of amentia and dementia, and this variation takes place according to the order of normal development, L.V., the first to appear, being the least affected, and L.II., the last to appear, being the most affected. In amentia, therefore, the condition is one of true subevolution, and in dementia one of true dissolution or involution. In the case of numbers 28 to 30, the depth indicated in L.II., and to some extent in L.III., does not show the actual amount of neuronic loss, owing to the existence in these cases of more or less extensive reparative proliferation of the non-neuronic elements of the cortex.

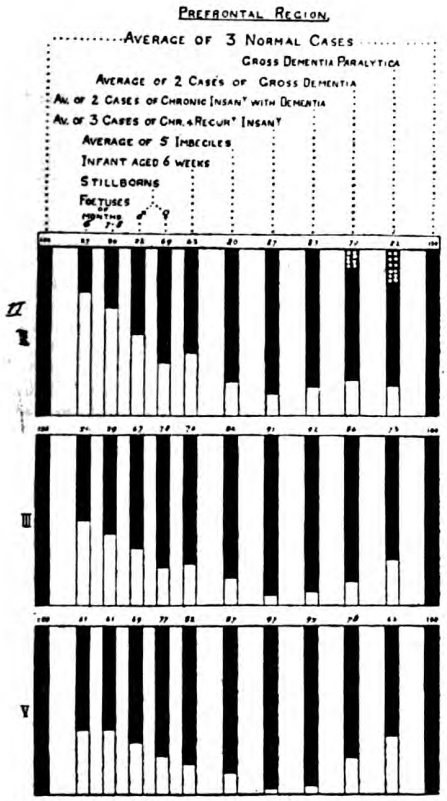
CONSIDERATION OF PRIMARY CELL LAMINÆ.

I will now pass to the consideration of the individual primary cell laminæ—namely, the second lamina or pyramidal layer, the third lamina or granule layer, and the fifth lamina or layer of polymorphic cells. These, as abstracted from the last plate, I will now show on the screen (Fig. 16).

It will be convenient to first consider all the three regions together from the general aspect and then to deal with each region individually.

In the case of the fifth lamina, it is evident that its depth in the visuo-sensory region is considerably less than—namely, about 13/16ths of—its depth in the visuo-psychic and prefrontal regions, whereas it is of exactly the same depth in the two last. Further, in the visuo-sensory region seven of the 12 abnormal cases reach to or above the normal line, whereas in the visuo-psychic region only five of 12, and in the prefrontal region but three of 15, excluding, of course, the three normals, which all reach it. The fifth lamina is thus, apart from the normal difference in depth, slightly better developed in the visuo-sensory region than in the visuo-psychic, and is much better developed in both these than in the prefrontal. Further, in the prefrontal region alone does this lamina in the several cases exhibit a gradation in depth which varies according to the degree of amentia and of dementia. This lamina is the first to be evolved during the development of the cortex, and rapidly attains to approximately the normal depth. It is only reasonably below the normal depth in the prefrontal region of infants, well-marked imbeciles, and gross dements, all of whom are unable to attend to the ordinary bodily functions, such as feeding, the calls of nature, &c. This lamina has been shown by G. A. Watson, as the result of his study of the cortex of the chief orders of the mammalia, to be the best developed and the most important cell layer of the neopallium. It is, therefore, impossible to avoid the conclusion that the inner cell lamina is the fundamental cell layer of the cortex, and that it is concerned with the performance of the instinctive, in contradistinction to the receptive, the psychic, and the voluntary psychic activities.

I now turn to the third lamina or granule layer. This lamina is exceptionally developed and complex in the visuo-sensory area, consisting of two granule layers with an interposed fibre layer, the line of Gennari, in which terminate the optic radiations. In the visuo-sensory area the lower of the two layers of granules is normally much deeper than is the same layer in the visuo-psychic and prefrontal regions, whereas the upper is slightly deeper than that in the visuo-psychic and of the same depth as that in the prefrontal region. Of these two layers of granules in the visuo-sensory area both in the series of cases reach the normal depth in only one instance, and the lower layer is throughout much better evolved than the upper. In the visuo-psychic area the granule lamina reaches up to or above the normal depth in 9 of the 12 cases. On the other hand, in the prefrontal region it is uniformly below the depth of the highest of the three normals in all the cases and well exhibits a gradation according to the degree of amentia and dementia. Being the lamina which is exceptionally evolved in the projection zones of the mammalian cortex, and being thus the layer which is especially concerned with the immediate transformation of afferent impressions, it is interesting to note the great variation in the degree of evolution of this lamina in the visuo-sensory region of the series of cases, and also that

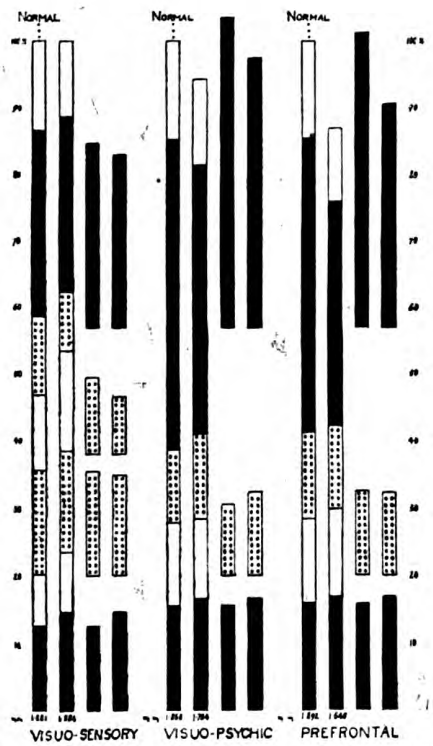


this variation is greater in the outer layer than the inner. I would further point out its relatively normal evolution in the visuo-psychic series and its subnormal depth in the prefrontal series.

It is, I think, easy to arrive at a reasonable explanation of these differences in degree of development. As I pointed out in the last lecture, the cortex of the visuo-sensory area is evolved earlier than that of the visuo-psychic, and this earlier than that of the prefrontal. It is, therefore, probable that in the case of the visuo-sensory area the individual differences in the middle cell or receptive lamina are indicative of individual differences in the functional capability of this lamina in different persons. On the other hand, in the prefrontal region the corresponding differences in the middle cell lamina are simply greater in degree than are those in the inner cell lamina and less than are those in the outer cell lamina, and are therefore due to the fact that the cortex of this region is, as a whole, in a condition of subevolution or dissolution according to the grade of amentia or dementia. In other words, the granule lamina of the visuo-sensory cortex exhibits considerable individual differences in its degree of evolution in different persons; the granule lamina of the visuo-psychic cortex does not, being usually developed up to or above the particular normal with which they are compared; and the granule lamina of the prefrontal cortex exhibits degrees of subevolution and dissolution that are part of the subevolution or dissolution of the whole cortex, which occurs in this region alone and varies in degree according to the existing grade of amentia or dementia.

I will now deal with the second lamina or pyramidal layer. This lamina passes the normal in one case in the visuo-sensory region, and in one of the three normal cases in the prefrontal region. In no other case does it reach the normal depth. In the visuo-sensory region it is in some cases better and in others worse evolved than in the visuo-psychic region. These differences bear no constant relationship to the degree of amentia or dementia. On the other hand, in the prefrontal region, the depth of this lamina varies directly according to the degree of amentia or dementia present. In normal evolution this lamina is the last of the cortical laminæ to be evolved, and it develops in the visuo-sensory area earlier than in the visuo-psychic, and in the visuo-psychic earlier than in the prefrontal region. It is poorly evolved in the lower mammalia, but rises in its degree of development during the ascent of the mammalian scale, as has been shown by G. A. Watson and by Brodmann. It is therefore concerned

FIG. 17.



PERCENTAGES OF AVERAGE DEPTHS, IN THE CASES OF LAYERS II., III. & V., ALL TO THE SAME SCALE IRRESPECTIVE OF ACTUAL DEPTH.

In this figure, for the purpose of direct comparison, the three cell layers of the prefrontal cortex of the cases which have been dealt with are averaged into percentages of the normal irrespective of actual depth. The figure proves that the inner cell lamina develops before the middle and the middle before the outer; that the same order of subevolution occurs in amentia, and that in dementia, if non-neuronic reparative proliferation of Laminæ II. and III. be allowed for, the last lamina to develop is the first to undergo dissolution, and the first the last.

FIG. 18.

MALE, AGED 44. WELL MARKED BUT NOT GROSS DEMENTIA. ENCEPHALON 1260 GRAMMES. WASTING SEVERE IN FRONTO-PARIETAL AND UPPER TEMPORAL REGIONS, BUT ESPECIALLY IN PREFRONTAL, AND OF AN UNUSUALLY PURE NEURONIC TYPE. CEREBRAL VESSELS NORMAL.

The figure shows, in comparison with the normal, the cortex of the visuo-sensory, the visuo-psychic, and the prefrontal regions of a case of well-marked dementia. From the aspect of total depth, the visuo-sensory area is normal, the visuo-psychic region shows a decrease of 6 per cent., and the prefrontal one of 13 per cent. In other words, the prefrontal region, which is the last to develop, shows the most affection, and the visuo-sensory area, which is the first to develop, shows the least. If the outer cell lamina or pyramidal layer be considered alone, there is a decrease of 6 per cent. in the visuo-sensory area, one of 13 per cent. in the visuo-psychic region, and one of 24 per cent. in the prefrontal. The middle cell lamina or granule layer exhibits an individual decrease in the visuo-sensory area, and is very well developed in the visuo-psychic and well developed in the prefrontal regions. The inner cell lamina is of a greater depth than that of the "normal" case in all the three regions, which fact suggests that the case under consideration was at any rate capable of development to a degree above that of this particular normal, even if this had not actually occurred.

with the psychic or associational, in contradistinction to the instinctive, activities of the cortex. From the table of measurements it may be concluded that these psychic or associational activities are in man pre-eminent and voluntary in the prefrontal region, that they are of less general but of more specialised significance in the visuo-psychic region, and that they are of much less, but nevertheless very specialised, significance in the visuo-sensory area, in which the second lamina is normally but five-ninths of its depth elsewhere. Further, the individual variations in depth in the visuo-sensory and visuo-psychic regions of the series of cases point to real individual differences in the specialised functional capability of these regions, whereas in the prefrontal region the differences are not of an individual nature but vary according to the degree of amentia or dementia which existed.

To turn finally to the general consideration of the cortex of each of these regions, I would again remind you that in normal evolution the visuo-sensory cortex develops before the visuo-psychic and the visuo-psychic before the prefrontal; and also that the inner cell lamina is evolved before the middle and the middle before the outer. In view of these facts it is evident from the study of the different series of cases that the visuo-sensory cortex is rather better evolved and much more specialised and individually variable than the visuo-psychic; that the visuo-psychic is better evolved than the prefrontal and that it also exhibits well-marked indications of specialisation and especially of individual variation; and that the prefrontal cortex shows clear indication, not of specialisation and individual variation, but of subevolution or dissolution according to the grade of amentia or dementia. I would also indicate that, as the three normal cases show, the degree of its evolution varies considerably in normal individuals.

In the case of the visuo-sensory area the specialisation is indicated by the great depth and complexity of the third or granule lamina and the markedly decreased normal depth of the second or pyramidal lamina and the somewhat decreased normal depth of the fifth lamina, whilst the individual variation is chiefly visible, though not necessarily in the same direction or to similar degrees, in the outer granule layer and the second or pyramidal lamina.

In the case of the visuo-psychic region the specialisation is indicated by facts of normal evolution which I pointed out in the last lecture, and by the well-developed third or granule lamina, and the individual variation is especially evident in the second or pyramidal lamina.

In the case of both regions it may be added that, specialisation being allowed for, whether the cases are considered individually or collectively, the degrees of evolution of the laminæ follow the normal order, the inner cell lamina being better developed than the outer or middle.

In the case of the prefrontal region, whether the cases be considered individually or collectively, there is direct evidence of degrees of subevolution according to the grade of amentia and of degrees of dissolution according to the grade of dementia. Further, this subevolution or dissolution involves the whole cortex, and this according to order of normal development, the inner cell lamina exhibiting the least decrease and the outer the most.

Lest this should be doubted by any statistician present, on the ground that the layers are not of the same depth, and that therefore exact comparison is not possible, I have, in the plate which I shall now show (Fig. 17), averaged together the depths of the laminæ of the various types of case and turned these depths into percentages so that each lamina appears of the same depth. It will be seen that the inner cell lamina is the first to be evolved, and the outer cell lamina the last; that the same order of subevolution applies according to the grade of amentia which existed; and that, in the case of dementia, also according to its grade, the outer cell lamina which is the last to be evolved is the first to undergo dissolution, and the inner cell lamina which is the first to be evolved is the last to undergo dissolution.

I will now complete this part of my subject by describing a special case in which I have exhaustively examined all the three regions under consideration. As far as it is possible to judge, the patient, before his illness, possessed at least the normal degree of intelligence, and probably more. In the course of less than two years he gradually developed a well-marked grade of dementia which was unusually profound for a man 44 years of age who did not suffer from degeneration of the cerebral arteries. The cerebral dissolution was therefore of an unusually pure neuronic type; and it seemed to me, in view of the originally good development of the brain, that a better case could not well be found for the exhibition of the different grades of cerebral dissolution which might be expected to be found on examination of the visuo-sensory, visuo-psychic, and prefrontal regions of the cortex, since it was probable that all these, in their original condition, were of at least the normal depth.

The results justified my expectation in that they showed quite clearly that the order of dissolution is the converse of that of normal evolution, the loss being most marked in the prefrontal region, next marked in the visuo-psychic zone, and least marked in the visuo-sensory area.

The results of the examination of this case are shown in the following diagram (Fig. 18), in which are contrasted, in percentages of the normal, the general average measurements of the visuo-sensory, visuo-pyschic, and prefrontal regions. From the aspect of total depth the visuo-sensory cortex is normal, the visuo-psychic shows a decrease of 6 per cent., and the prefrontal one of 13 per cent. When the laminæ are individually considered there is, in the case of the outer cell lamina or pyramidal layer, a 6 per cent. decrease in depth in the visuo-sensory area, a 13 per cent. decrease in depth in the visuo-psychic region, and a 24 per cent. decrease in depth in the prefrontal region. The middle cell or granule lamina is much below the normal in the visuo-sensory area; it is well above the normal in the visuo-psychic zone and it is of practically the normal depth in the prefrontal region. The inner cell or polymorphic lamina is considerably above the normal depth in the visuo-sensory area and is well above it in the visuo-psychic and prefrontal regions. Whilst it is impossible to be certain as to whether the cortex was originally fully evolved or not, it is obvious that the visuo-sensory area possesses an individually deficient granule or receptive lamina, and had commenced evolution in a manner which should have carried it beyond the level of the normal case. The latter remark applies equally to the visuo-psychic and prefrontal regions. If, however, the cortex of this case be credited merely with evolution up to the level of the normal case, the significant fact appears that the pyramidal or psychic lamina has become decreased in depth by 24 per cent. in the prefrontal region, by 13 per cent in the visuo-psychic zone, and by 6 per cent. in the visuo-sensory area.

SUMMARY OF RESULTS OF MICROMETRIC STUDIES.

As a summary of the results of my micrometric studies I would remark that the human cerebral cortex is originally evolved from three primary cell laminæ, an inner or polymorphic, which is concerned with the performance of organic and non-voluntary activities; a middle or granule, which is receptive in function; and an outer or pyramidal, which serves as the physical basis of the associative functions of the cerebrum. The last of these, as has been shown by the investigations of John Turner and of G. A. Watson, is the distinctive feature of the cortex peculiar to the mammalia, or the neopallium, to employ the term introduced by Elliot Smith. These three laminæ appear during normal development in the order in which I have stated them—namely, from within outwards—and the cortex of the visuo-sensory area is evolved before that of the visuo-psychic zone, and this before that of the prefrontal region.

In cases of mental disease grading from idiots and imbeciles through various types of non-demented and partially demented lunatics to the gross dement, marked differences in the degree of evolution and dissolution of the cortex exist, which, considered from the general aspect, follow the order of normal development. In amentia the condition is one of subevolution to different degrees; and in dementia the laminæ suffer in the reverse order to that of their evolution, the most affected being the latest developed, and the least affected being the earliest developed. The degree and type of these differences vary according to the region of the cortex, whether this be a projection area, a zone of special association, or the prefrontal region. In the case of the visuo-sensory area the prominent features are poor evolution of the pyramidal and polymorphic laminæ, and specialisation of the granule or receptive lamina. There also exist individual variations in the degree of evolution of the granule or receptive lamina, and in that of the pyramidal or associative lamina, which individual variations bear no

relationship to the degrees of amentia or dementia which exist in individual cases.

In the case of the visuo-psychic zone, the important feature, apart from an especially good evolution of the granule or receptive lamina, is a marked degree of individual variation with regard to the depth of the pyramidal or associative lamina. This individual variation is not only independent of the existing grade of amentia or dementia, but also of the individual variation in this lamina which occurs in the visuo-sensory area.

In the case of the prefrontal region, both specialisation and individual variation are practically or entirely absent, and the cortex merely exhibits degrees of subevolution or dissolution which vary according to the grade of amentia or dementia which exists in the individual cases. That the condition is one of true subevolution is shown by the fact that the laminæ are subevolved in the order of their normal development, the last to appear being the least developed and the first the most. The reverse order holds with regard to dissolution, the last lamina to appear during normal development being the first to undergo retrogression in dementia, and the first the last. In the case of the cortex of the prefrontal region, therefore, the associative function of the pyramidal lamina may be regarded as "*voluntary* associative," in view of the fact that the essential feature of amentia and dementia is decrease, instability, or loss of voluntary control over the processes of cerebral association.

As a final remark I would add that there is reason to believe that this physical basis of the cerebral functions, which exhibits such well-marked variations in the subjects of mental alienation, exhibits equally important though less extensive variations in the case of presumably normal individuals, and thus indicates a structural origin for individual differences in mental endowment.

THE MODERN TREATMENT OF PULMONARY TUBERCULOSIS.[1]

BY FRANK J. WETHERED, M.D. LOND., F.R.C.P. LOND.,

PHYSICIAN TO THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON; PHYSICIAN (WITH CARE OF OUT-PATIENTS) TO THE MIDDLESEX HOSPITAL, LONDON.

THE treatment of pulmonary tuberculosis, in common with that of most other diseases, has undergone many vicissitudes. With the discovery of the pathogenic bacillus by Koch the hopes of the profession all over the world rose, and it was believed that some definite line of treatment based on the destruction of the bacillus would soon be forthcoming. Consequently, all manner of efforts to kill the bacillus *in situ* by means of drugs were tried. Drugs which had been shown to have bactericidal properties were administered by the mouth, by inhalation, by subcutaneous injection, and by injection into the veins. Many observers claimed success by one or other of these measures, but no genuine advance was made, and one by one they dropped out of general use.

Improvement certainly seems occasionally to follow the administration of certain medicaments. Cod-liver oil, especially when combined with the hypophosphites, has been employed for years, and is still largely given. When the patient has a poor appetite, or when suitable food is unattainable, the oil has a beneficial action, and is so given largely in out-patient practice. In these circumstances it aids nutrition, but if appetite is good, digestion satisfactory, and sufficient good food can be obtained, its value is much lessened, its place being taken by the ordinary food matters. The prescription which has probably borne the test of time better than any other I consider to be the alkaline gentian mixture contained in the pharmacopœia of most of the hospitals—carbonate of soda or potash, gentian, and certain carminatives. Taken before food, perhaps with the addition of some tincture of nux vomica, it stimulates appetite and promotes digestion.

The creasote series of drugs have also been largely employed, either creasote in capsules, or guaiacol or its carbonates being most frequently used. Personally, I prefer creasote given in doses of one to three minims after meals, not on account of any specific effect that it may have on the tuberculous process, for I know of no proof of such an action, but to take advantage of its action in preventing fermentation in the intestinal tract, and so improving the digestive process.

The above measures are now combined with rest, abundance of good food, and the free access of air. Rest is essential if there is any rise of temperature during the 24 hours; I generally insist on confinement to the reclining posture if the temperature rises above 99° F. in men and 99·2° in women. If higher than 99·4° I think rest in bed is indicated. If the swing of the temperature is excessive, and the temperature rises above 100·5°, I advise *absolute* rest for some days; that is to say, treating the patient as for typhoid fever except as regards diet. Under such stringent measures a lower and more satisfactory range of temperature is frequently procured. A high, swinging temperature is frequently maintained by a hard, frequent, violent cough, and until the cough ameliorates the patient will undergo a series of auto-inoculations, effectually preventing a favourable progress. Sedatives should then be tried, a morphia linctus, heroin, codeia, or an inhalation of menthol (20 per cent.) and spirit of chloroform.

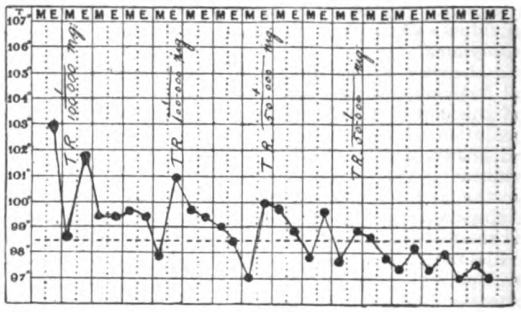
Nearly 20 years ago what was then termed the "open-air treatment" began to be adopted in this country, although for several years previously it had been carried out by Brehmer, Dettweiler, and other physicians on the continent. A more advanced method was introduced by Walther at Nordrach. One of the most important points of Walther's treatment was the insistence on graduated walking exercise, and this modification of the continuous rest which had hitherto been largely used was the introduction to the graduated labour treatment, to which I shall presently refer. In these preliminary remarks on the "open-air" treatment it is only fair to remind you that this method was advocated and carried into practice in this country as long ago as 1833 by Mr. Bodington of Sutton Coldfield. He published a book on the subject in 1840, and the manner in which his proposals were received by the medical profession at that time is exemplified by a review which appeared in THE LANCET in July, 1840. The following is an extract:—

> The modest and rational preface with which the author introduces to us his pamphlet on pulmonary consumption has so far influenced us in his favour that we shall merely give an outline of his principles, without expending any portion of our critical wrath on his very crude ideas and unsupported assertions. ..... The measures, then, which Mr. Bodington assures have been uniformly and completely successful in the treatment of several cases of tuberculous consumption are detailed. ..... More agreeable or seductive medicaments could not certainly be found in any pharmacopœia; fresh morning air to make the patient breathe; good wine to bring down his pulse, a good dinner to make him fat, and an opium pill to make him sleep, are all excellent remedies if they would only have the desired effects.

Mr. Bodington did not live to see the movement developed to its modern extent, nor, indeed, to enjoy the recognition of his shrewd observation and foresight. In a private letter to his son in 1866 he wrote: "I often think that, when I am dead and buried, perhaps the profession will be more disposed to do me some justice than whilst I live."

The "sanatorium treatment" has now been extensively tried in this country with encouraging results, but some observers have felt that the constant exposure to fresh air and abundance of good food did not fully account for the benefits received. Nevertheless, under the methods already mentioned, or, as more recently adopted, a combination of them, a certain amount of success has been obtained. The exact explanation of the improvement manifested is open to discussion. Until quite recently it was looked upon (and still is by some) as a hardening process. Certain vague terms were used such as "increasing the patient's resistance," or "rendering the tissues a less favourable nidus for the growth of the tubercle bacillus." To these considerations another pathological one may be added—namely, that the post-mortem records of the general hospitals show that of those patients dying from some other disease than tuberculosis, a certain percentage (about 12 per cent. at the Middlesex Hospital) manifest indications of arrested or healed tubercle in the lungs, showing that a spontaneous arrest or even cure is possible.

Satisfactory progress is made by many patients under the methods of treatment commonly employed, but in only too many no response follows, and even in a greater number the improvement is only temporary. Tuberculosis is a disease due to a specific organism. In addition to local



[1] Founded on a lecture delivered at the Medical Graduates' College and Polyclinic.

changes, constitutional disturbances are produced by means of the toxins, and in order to combat these effects substances must be brought into play that antagonise their action. The very valuable work of Sir Almroth Wright has had great influence in establishing a scientific basis upon which to work. The demonstration of the opsonins and the methods which permit of the opsonic index being taken formed the early steps in the elucidation of a problem which had hitherto defied explanation. Then followed the demonstration of an equally important phenomenon—that of auto-inoculation. Hetero-inoculation—the insertion of vaccines by artificial means—had been already practised, and it is an application of the two methods, hetero- and auto-inoculation, that forms the basis of the modern treatment of pulmonary tuberculosis.

I will first speak of hetero-inoculation, for in some instances this of necessity is the first stage. The rush to Berlin when Koch first introduced tuberculin may be remembered by some of you. Unfortunately, in the hands of most observers the method then adopted was a failure, although some physicians have never discarded it, and still claim for it success. When Sir A. Wright first introduced the opsonic index as a guide to the inoculation of tuberculin he insisted on the necessity of not repeating a dose of the remedy until the effect of the previous one had passed off. I consider this of great importance, and it is upon this principle I always act when employing tuberculin. The German method of administering the drug is to push it until a febrile reaction occurs. I do not agree with this plan, and, moreover, it has the disadvantage of being only applicable to afebrile cases. Sir A. Wright clearly demonstrated that the machinery of immunisation could be brought into action by very small stimuli, and that it could very easily be overtaxed. The chief drawback to Sir A. Wright's method is the technique required to estimate the opsonic index; this is so complicated that only a few experts can obtain uniform consistent results. Dr. A. C. Inman, however, has demonstrated a ratio between the curves of the opsonic index and temperature. Working on these lines I always employ very small doses in the following way.

I have hitherto only tried tuberculin in cases in which there has been a rise of temperature. I know that it has been stated that these are unfavourable ones, but they are precisely those in which some new method of procedure is urgently needed. If the remedy is only employed in afebrile cases it is difficult to ascertain the amount of benefit derived; such cases generally progress favourably by the ordinary routine methods, and it is by employing new methods in afebrile cases that so many "cures" for the disease are so frequently announced. In order that a definite conclusion can be arrived at in such instances, a lapse of several years (I should name seven as the minimum) is necessary in order to watch for relapses. I can, of course, only state my immediate results, but I can say this: that I am encouraged by the progress of many of the patients, although I chose such unsatisfactory material to work upon, and I believe that as experience is gained the method will be improved. One of the difficulties at present met with is to judge how far to push the doses. I commence with 1/100,000th milligramme of tuberculin (T.R.) given by the mouth. I usually advise it to be taken with a little milk. If it is administered hypodermically half the above dose is the equivalent. It is best given on an empty stomach. Further, I order it to be taken when the temperature is raised. If, therefore, the temperature curve is of the ordinary type, 10.30 P.M. is a convenient time, but if the type is inverse, then early morning is the right time. My object in thus giving it is as follows. Dr. Inman has shown (and his researches have been corroborated by other observers) that the opsonic index varies inversely with the temperature—i.e., when the temperature is high the index is low, and *vice versâ*. Further, there is a slight delay in the movement of the temperature following that of the index. For instance, the index has begun to rise before the temperature has begun to fall; consequently, if the tuberculin is given at 10.30 P.M. in all probability it is being administered on a rising opsonic index—that is to say during the commencement of the positive phase, and that I believe, from clinical experience, is the most advantageous period to give it. The effect on the temperature is carefully watched and the patient's general symptoms are noted. As I have before said, it is important not to give a second dose before the effects of the previous one have passed off. If the dose has had a definite favourable effect there will be produced a "flattening" of the temperature curve; the degree of flattening varies. (Fig. 1.)

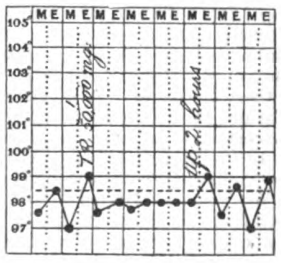


FIG. 1.

I do not think that it is desirable to obtain a febrile reaction, although I am aware that this practice is contrary to that of some other physicians, and, as I have already said, if the temperature has been previously raised it is difficult to judge by the chart if an excessive dose has been given. Certain symptoms, however, are suggestive of the action of too large a dose, especially headache, loss of appetite, undue quickening of the pulse, and occasionally pain in the side. If these phenomena present themselves, the next dose should be smaller. If no effect is produced in about 48 hours, a larger dose is given, that is to say 1/50,000th milligramme, and the effect is again noted. If a flattening of the curve is produced, one must wait until the temperature again begins to swing before another dose is given, then the same dose is repeated. If then no effect is produced, a larger dose may be given. In some instances the same dose may be successful in producing an immunising action on several occasions, before an increase is found necessary. In this manner the dose is gradually increased. I do not usually go beyond 1/2000th milligramme, but I should not hesitate to do so if I thought occasion required it.

I have tried this method in numerous cases, and with encouraging results. In some cases, however, no effect has been produced. In a few the temperature has been markedly lowered, the antipyretic action of the tuberculin being most marked (Fig. 2); in most cases of this class, however, the

FIG. 2.

disease was very active and extensive, and no permanent good could have been hoped for; nevertheless, the temperature was reduced, and the patient felt relieved, but no apparent effect was made on the course of the disease. The class of case in which the most favourable results were obtained was that in which the temperature was afebrile or exhibited only slight rises whilst the patient was kept confined to bed, but as soon as he was allowed to get up an irregular temperature was at once manifested. When the method of treatment I have described was adopted, the case at once assumed a more favourable aspect. I look upon this type of case as one in which the individual is not able to control auto-inoculation, which occurs as soon as exercise is taken. I think one is justified in assuming that by gradually increasing the amount of tuberculin the patient is gradually rendered immune to the amount of "tuberculin"

which he himself can manufacture, so that subsequently he can take an increasing amount of exercise without any bad results.

I now come to speak of auto-inoculation. For want of a better term I shall assume that the patient inoculates himself with a substance similar to the manufactured "tuberculin." In acute cases the auto-inoculations occur irregularly and there seems to be but little control over them. In other cases auto-inoculation only takes place when the patient is up and taking exercise. To quote the words of Sir A. Wright: "Auto-inoculations follow upon all active and passive movements which affect a focus of infection and upon all vascular changes which activate the lymph stream in such a focus."

I have already mentioned that some observers were not satisfied with the explanations given for the beneficial effects undoubtedly conferred by "sanatorium treatment." Dr. M. S. Paterson, the medical superintendent of the Brompton Hospital Sanatorium at Frimley, observed that many tuberculous patients who had followed their ordinary occupations up to the time of admission were in a very fair condition of health. Acting on this he has evolved a system of treatment known as the "graduated labour" treatment of pulmonary tuberculosis, though this is no longer an accurate title, as rest, or "graduated rest," is now an important element. I may at once say that this method of treatment can be perfectly well carried out in private practice provided that its principles are thoroughly understood, that the patient is willing to place himself under the directions of his medical attendant, that the supervision can be constant, and that the requisite garden or piece of land is near in which the "labour" is to be conducted. At first the treatment was carried out empirically, but Dr. Inman made the very interesting and valuable observations that the opsonic indices in the patients under treatment indicated that the exercise supplied the stimulus necessary to induce artificial auto-inoculation, and that systematic graduation of exercise will regulate auto-intoxication in point of time and amount. Dr. Paterson has since found that with the aid of the opsonic index he can regulate the stimulus with scientific accuracy and obtain his results more certainly and more rapidly. For the two original papers by Dr. Inman and Dr. Paterson respectively I refer you to THE LANCET of Jan. 25th, 1908.

As I have said, the same treatment can be carried out in private. The first essential is that the patients must be in the afebrile stage both whilst at rest and on slight exertion. I always advise that the temperature should be taken three times a day—at about 8 A.M., between 4 and 6 o'clock in the afternoon, and again at night. If the temperature does not rise above 99° F. in the 24 hours whilst the patient is in bed, he is allowed up for two hours and allowed to move about slowly; the time is gradually increased until he is up all day, only a very slight amount of walking exercise being allowed. When he is proved to be afebrile under these conditions he is told to walk a measured mile at the rate of two miles an hour, then to rest for half an hour, and then to take his temperature. I have always found the mouth temperature perfectly accurate for all practical purposes provided that the thermometer is allowed to remain at least five minutes in the closed mouth. As there are obvious objections to the inconvenience of taking the rectal temperature this is an advantage. It may be misleading to take the temperature immediately after exercise. The temperature of a healthy individual is often raised by exercise, but speedily regains the normal, whilst in a tuberculous subject, not yet able to control his own inoculations, the temperature may remain raised for some hours. If the temperature remains below 99° after this amount of exercise, and the pulse is not unduly quickened by it, on the following day he is allowed to walk one mile in the morning and one in the afternoon, under the same conditions. The length of walk is thus gradually increased until three miles are walked in the morning and three in the afternoon.

I must here pause to call your attention to another point in connexion with the temperature chart. In carrying out this method of treatment the swing of the temperature is of importance, even if the swing be subnormal. A satisfactory response to the exercise is the same as after the administration of tuberculin—namely, a flattening of the curve. If, therefore, the swing is a wide one, the increase in the amount of exercise must be regulated with much more care than when it is small, and other symptoms of over-dosage must be watched for. The first to be noticed is generally loss of appetite. A patient undergoing "graduated labour" should proceed to his meals with a good appetite and readily dispose of the food placed before him. If he toys with his meals further inquiry will probably elicit that he is not feeling perfectly well and is listless, and in most cases he admits to a headache. Under such circumstances he must be directed to rest on his bed for the remainder of that day and perhaps for the following day also. If the overdose has been excessive a pain in the side is also a common symptom.

If the six miles of walking exercise is accomplished successfully light manual labour is allowed, first for one hour, gradually increased to six—three hours in the morning and three in the afternoon. A rest of one hour before the midday meal is important. This should be rest in the reclining posture and not merely sitting in a chair, and this is to be absolutely enforced during the earlier stages. During the whole of the treatment the guide of the temperature chart must not be relaxed. The nature of the manual labour must, of course, be guided by circumstances. Carrying light weights up a slight incline is a good commencement. By light weights I suggest small baskets full of leaves, sand, or gravel; then heavier baskets carried longer distances. Then hoeing in broken ground or the use of a light rake. The presence of a chicken-run is, of course, most helpful, as offering various forms of "labour." The test used at Frimley to indicate that a patient has approached the end of his course of treatment is, that he can work for six hours daily with a navvy's heavy pick and shovel without exhibiting any signs of auto-inoculation, showing that he is immune to the dose that that amount of work can evoke. In addition, the symptoms of disease should have practically disappeared, although there is still sometimes a slight amount of sputum in the morning. The physical signs may not have completely disappeared, and the indications of a healing or arrested lesion may, of course, be present for some considerable period. The length of time required for a complete course naturally varies with each individual case, but four months may probably be taken as the minimum.

It is not very often that the effects of an excessive dose are manifested if the patient carefully follows his medical attendant's orders. To avoid this I think it is very wise to take the patient into one's confidence—to explain to him in simple language the rationale of the treatment, and to tell him something about auto-inoculation and its dangers. Some patients are intensely stupid and dense in spite of these precautions. It is not uncommon, even in the private sanatoriums, where some guineas are paid weekly, for a patient to "fake" his temperature in order not to be kept in bed. Anything more foolish can scarcely be imagined; the only person injured is the patient himself, and in consequence he may be thrown back several weeks. The majority of the patients readily realise that the medical man knows more than they do about the disease, and so faithfully follow out instructions.

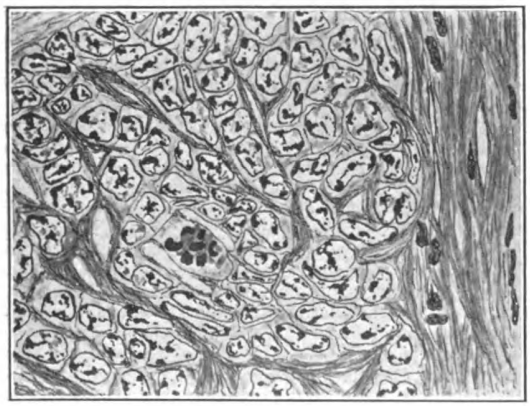
An overdose is generally due to exceeding instructions. For instance, a man on light basket work may take hold of a heavy shovel and dig vigorously with disastrous results. Therefore constant and strict supervision is required in the early stages of the treatment. Should the results of an overdose manifest themselves absolute rest for some days is indicated—that is, treating the patient as though he were suffering from typhoid fever. In three days or so the temperature will again become normal, when graduated rest may be employed. The patient may be allowed to wash himself in bed; next day he is allowed to do away with the use of the bedpan, then to be up for one hour, and so on. In this way the effects of over auto-inoculation are best combated.

From the various facts and methods which I have considered I would contend that the modern treatment of pulmonary tuberculosis rests upon the establishment of immunity. In order to procure this, it is, in the first place, necessary to prevent excessive auto-inoculation. The method most likely to effect this result is rest. Hence the benefit that accrues by the routine treatment hitherto adopted at special hospitals and sanatoriums—rest in bed until the temperature is normal. Subsequently the production of auto-inoculation by suitable exercise, rendering the patient immune to increasing doses of self-manufactured tuberculin. If this is not possible, then immunity may be induced by hetero-inoculation.

Harley-street, W.

THE EFFECTS OF A SERUM UPON A CARCINOMA OCCURRING IN MICE.

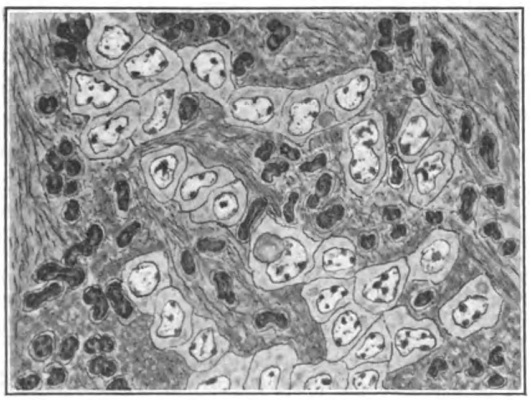
BY CHARLES WALKER, M.SC. LIVERP., M.R.C.S. ENG., L.R.C.P. LOND., &C.



IN THE LANCET of Sept. 12th, 1908 (p. 797), some experiments with two sera upon a carcinoma occurring in mice were described. In the belief that the cells both of the testis and of malignant growths are out of coördination with the rest of the cells of the body, rats were injected with an emulsion of the living cells of the testis of the mouse, in the hope of producing in the serum of the rat something which would be destructive to all those cells in the mouse which were out of coördination with the rest of the body. The same thing was done in other rats, substituting a preparation of the cells of the carcinoma for those of the testis. The sera obtained from the rats were injected into mice with already well-developed carcinoma, and the results of these injections were summarised as follows:—

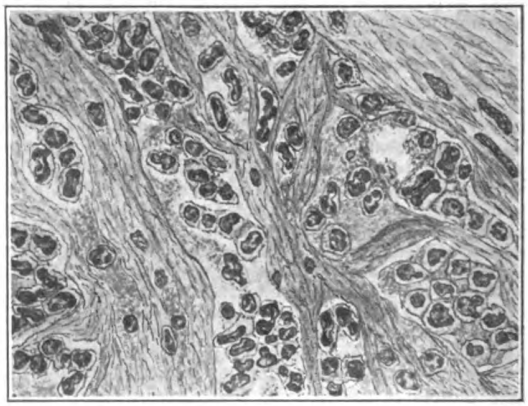
1. In 743 mice not treated with either of these two sera the tumours in two have dried up and dropped off spontaneously. 2. In a batch of ten mice treated with testis serum obtained 14 days after last injection of rat, the tumours in seven became suddenly gangrenous. In one the tumour dried up and came away. 3. In a batch of ten mice treated with tumour serum obtained 14 days after last injection of rat, the tumours in seven dried up and came away as small scabs. 4. In mice treated with testis or tumour serum taken from rats killed eight days after the last injection, the tumours became markedly hyperæmic. They did not in mice treated with normal rat serum. They also grew more rapidly than the tumours in mice treated with normal serum. 5. In mice treated with testis or tumour serum taken from rats killed 14 days after the last injection, tumours grew at much less than half the rate of the tumours in mice treated with normal rat serum.

These experiments were subsequently repeated and similar results were obtained, but negative results followed the injection of the serum of rats treated with the testis of rabbits and guinea-pigs into mice suffering from carcinoma.



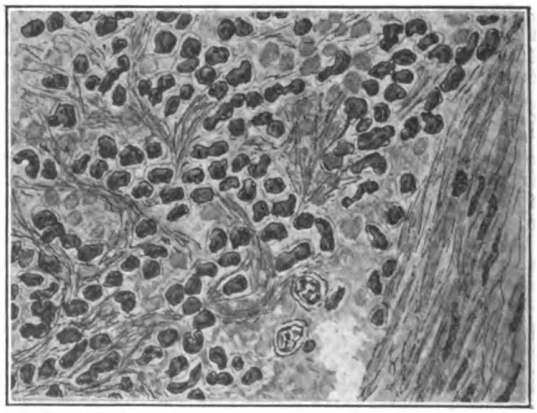
Returning to the original serum obtained by the injection of mouse's testis into the rat, the following experiments were conducted with a view of finding out whether the clinical results could be confirmed by the action of the serum upon the tumour cells *in vitro*. The serum was prepared in exactly the same way as described in the communication already referred to. Small portions of the mouse carcinoma (about 2 millimetres in diameter) were placed in the serum immediately after removal from the mouse, and were then kept in an incubator at 36° C. At the same time similar portions of the same tumour were placed under similar conditions in normal rat serum. In order to insure as far as possible similar portions of tumour being placed in the normal and in the active sera, the following precautions were taken. The most healthy and active portion of the tumour is usually at the periphery. The healthy and growing portion of the tumour has a semi-translucent appearance as compared with those portions where a number of the cells are breaking down. Familiarity with the naked-eye appearance of the tumour makes it comparatively easy to choose healthy portions. In this case slices about 2 millimetres thick were cut from the periphery of the tumour, and, discarding all but those parts which appeared healthy, was cut into small cubes

FIG. 1.



Microscopical appearance of piece of tumour fixed immediately after removal from mouse.

FIG. 2.



Microscopical appearance of piece of tumour after being for 48 hours in normal rat serum.

FIG. 3.

FIG. 4.

Microscopical appearance of tumour from mouse after treatment with testis serum.

of about 2 millimetres in diameter. Adjacent pieces were placed, one in the active and one in the normal serum. Moreover, several pairs of cubes from different portions of the tumour were treated in this way.

After these pieces of tumour had been left in the sera for 48 hours they were removed, fixed, sectioned, and stained. From microscopical examination it was evident that the majority of the cells present in both series of sections were alive, but here the resemblance ended. In the pieces of tumour which had been for 48 hours in normal rat serum a large number of apparently healthy tumour cells were present. The comparison of Fig. 1, which represents a piece of tumour fixed immediately upon removal from the mouse, with Fig. 2, which represents a portion of the same tumour fixed after being left for 48 hours in normal rat serum at a temperature of 36° C., shows that although a number of typical tumour cells are still present they have been replaced to a considerable extent by leucocytes, connective-tissue cells, and débris. In the case of the portions of tumour placed in the serum of rats treated with mouse's testis, the typical appearance was that shown in Fig. 3. In no instance in the many sections prepared from several portions of the tumour thus treated was a single unmistakeable tumour cell still visible. The number of small round cells and polymorphonuclear leucocytes is enormously increased. There is a good deal of débris, but still a number of apparently healthy cells are present, which have taken the place of the tumour cells.

It will appear then, that while normal rat serum, under the conditions described, leaves a large number of the cells of this particular carcinoma in mice in an apparently healthy condition at the end of a period of 48 hours, the serum of the rats treated with mouse's testis produces a destruction of the tumour cells, although, it apparently allows, at the same time, other cells to proliferate. A large number of these small cells which take the place of the cancer cells are apparently leucocytes. A comparison between them and the spleen and the bone marrow of the mouse makes this obvious without going into particular details. It is, of course, possible that some of the cells may not be normal leucocytes or derived from leucocytes. The conditions being obviously abnormal it is only to be expected that if they are all of them leucocytes, as I am inclined to think, the appearance in many cases must vary considerably from the normal varieties of leucocytes. A large number of them, however, are typical, being mainly lymphocytes and polymorphonuclear leucocytes. Some, too, contain granules. There is also apparently an increase of connective tissue cells.

There is, of course, a possibility that some of the cells found after treatment with the testis serum may be modified cancer cells. While it is at present impossible to make an absolutely definite statement with regard to this point, it seems very improbable. No intermediate cells between the cancer cells and those existing after 48 hours in the incubator are to be found. We go straight from the unmistakeable cancer cell to cells which possess not a single one of their characteristic features, and which are never more than about a quarter of their size. It is the same in the case of the tumour treated with normal rat serum. The cancer cells which have survived still possess the characteristic features, and are quite unmistakeable. The small cells are far more numerous than they are in the tumour fixed immediately upon removal, but there are no signs of intermediate stages. On the other hand, every gradation between the typical leucocyte or connective tissue cell and the cells found in the tumour after treatment, both with normal and testis serum, are easily traceable. While, therefore, it seems highly probable that the cancer cells are replaced by leucocytes or by cells derived from leucocytes, there is no evidence whatever that the cancer cells become modified into the smaller cells.

Another point is the comparison between the microscopic appearance of the tumour from a mouse which has not been treated, and that of a tumour which was diminishing in size after ten days' treatment of the mouse with testis serum. (Fig. 4.) Here the cancer cells had completely disappeared and were replaced by leucocytes, and possibly other small cells, although, for the same reasons as those given above, I take them all to be leucocytes.

If this interpretation be correct, it will appear that what happens upon the treatment of a mouse suffering from cancer with the testis serum is rather the stimulation of the leucocytes to multiply and replace the cells of the tumour than a direct destructive influence on the part of the serum upon the cancer cells themselves.

The same experiments were performed with tumour serum, and results similar to those described here as having followed the use of testis serum were obtained. As, however, the tumour serum experiments were only carried through once, while the testis serum experiments were repeated, it is not proposed to give the details of the former. The testis serum, though it did not give in the experiments done upon cancerous mice as good results as the tumour serum, is probably of more importance as being of more general application.

Some attempts were made in conjunction with Dr. Ernest E. Glynn to demonstrate the effect of the serum by mixing it with emulsions of the cancer cells. Emulsions of the cancer cells were made with normal saline solution and mixed with serum, and in some cases leucocytes from the mouse were added. It was impossible, however, to arrive at any certain conclusions by these methods. If any differences existed between the cells that had been kept in normal and in testis serum they were of such a nature as to escape our observation, and the best preparations that could be produced were insufficient to give any satisfactory evidence.

Liverpool.

EXPERIMENTAL DIMINUTION OF RESISTANCE TO MOUSE CANCER.

BY ARCHIBALD LEITCH, M.B. GLASG.,
PATHOLOGIST TO THE CAIRD CANCER RESEARCH LABORATORY, DUNDEE.

AFTER the difficulties attending the propagation of cancerous tumours in mice had been overcome, the problems of the modification of resistance to inoculation at once presented themselves. Many attempts have been made to protect mice by vaccination against subsequent injection of cancer material, but up to the present time only a certain measure of success can be said to have attended these efforts. It was found that in many cases the injection of mouse cancer cells failed to produce tumours, or that after a brief growth the tumours retrogressed and were absorbed, and that in such cases subsequent inoculation of cancer was without effect—a sort of immunity had been produced. The serum of these resistant animals did not seem to contain anything in the nature of an antibody specifically directed against cancer cells. It was no more efficacious in preventing growth when tried on fresh animals than was normal mouse serum. The latter did, however, sometimes give an apparent, though feeble, protection. The most promising results were obtained by vaccinating the animal with living cancer cells. Generally speaking, a certain quantity of material, which varies with different tumour strains, is necessary for the production of tumours; and by diminishing the necessary minimal dose, or in some cases by increasing the maximum dose, a condition was frequently produced whereby the animals proved resistant to the ordinary dose used as a test. Often, however, the "protecting" inoculation failed to have this effect, and even in many cases it, by itself, gave rise to tumour growths. Exposure of tumour cells to extreme cold—e.g., that of liquid air, or the preservation of tumours removed from animals for long periods of time, did not succeed in absolutely destroying the proliferative capacity of the cells. Chemical reagents or heat, though destroying this capacity of growth, destroyed also the chemical constitution of the cell protoplasm, and material so treated was without effect in protecting animals against subsequent inoculation with living cells. The injection of mouse embryo epithelium, however, gave promising results when used to vaccinate mice against squamous-cell carcinoma and to a small extent against adeno-carcinoma. From a survey of these attempts it might have been concluded that success followed where the vaccinating material was deprived of proliferative power and chemically unchanged, and that it failed when either of the opposite conditions obtained. If, then, we could destroy the physical constitution of cancer cells without alteration of their chemical constitution it might be supposed that we would have in our hands a more certain protective material.

After many attempts, into which I shall not enter here, I used the following method for disintegrating the cells. Transplanted tumours of one particular strain were removed from several mice, and after being roughly disintegrated

with small scissors were thoroughly triturated in a mortar with fine silver sand. The resulting pasty mass was transferred to bottles containing sterile saline solution and the whole shaken up. Strict aseptic precautions were, of course, observed throughout. The bottles were kept in a cold chamber for two days, and thereafter the subsequent fluid was decanted into test-tubes, which were kept at freezing point until required. This fluid remained turbid for at least a month, though there was a gradual accumulation at the bottom of the tubes; it was bacteriologically sterile and did not contain living cells as far as could be observed by microscopic examination or the results of injection. The chemical nature of the protoplasm was presumably not altered. (It may be noted that even advanced autolysis does not prevent growth on inoculation.)

The fluid was injected into the peritoneum of a number of mice on three occasions with ten days' intervals, employing for the first injection 0·5 cubic centimetre and 1 cubic centimetre for the last two. As the material was not standardised, it can only be said that in comparison with the ordinary quantity of tumour emulsion used for transplantations (in this case 0·05 cubic centimetre) it represented an excessively minute dose of epithelium. 24 days after the last intraperitoneal injection the 29 mice that survived were inoculated subcutaneously in the usual way with 0·05 cubic centimetre of fresh tumour emulsion. A similar number of controls were instituted.

The treatment, instead of increasing the resistance to test inoculation, had a marked effect to the contrary. In ten days' time, of the 27 treated mice that remained alive, 18 showed tumours; a week later, 21 out of the 27 (78 per cent.) had growing cancers. The controls gave 9 tumours in 27 mice (33 per cent.). There is a striking disparity between the two sets. But this disparity is all the more marked when we take into account the size of the tumours produced in both cases. By carefully mapping out the contours of the tumours on graph paper it was found that the average area covered by the tumours in the treated set was approximately 110 square millimetres, as compared with an area of 39 square millimetres in the case of the controls. The average mass is much larger.

The tumour used throughout these experiments was an adeno-carcinoma—"No. 63" of the Imperial Cancer Research Fund list—and I am deeply indebted to the superintendent of these laboratories for his kindness in placing material at my disposal. For a few months this tumour grew well, succeeding in a very high percentage of cases. Thereafter the successful "takes" rapidly diminished until it failed completely. This has proved a fortunate accident as far as these experiments are concerned. For my test inoculations I was confined to a single tumour 3½ months old which had been growing very slowly and which did not show the central necrosis so common in this strain. The sudden resuscitation in the treated series is all the more remarkable.

From these preliminary experiments it is evident that the injection of cancer cells which are physically disintegrated without probably being chemically altered has markedly affected the resistance towards living tumour cells. So far from conferring anything in the nature of immunity it has undoubtedly exalted the susceptibility.

Note.—I have evidently been working on similar lines to Dr. M Haaland, whose paper was published in THE LANCET of March 19th last. Owing to the fact that his tumour was "taking" normally in a high percentage of cases, the increase of susceptibility is not so evident as in the above experiments where the testing tumour is in a "dormant" phase.

Dundee.

THE HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, BROMPTON.—The lectures and demonstrations at this hospital for the forthcoming summer term will commence on Aprll 13th with a lecture by Dr. J. Kingston Fowler on the diagnosis, prognosis, and treatment of pneumonia. The lectures, which will be continued on the succeeding Wednesdays in April, May, and June, will be announced week by week in the Medical Diary of THE LANCET. On Thursday, May 26th, Dr. F. J. Wethered will give a demonstration at Frimley Sanatorium. The lectures and demonstrations are free to all qualified medical practitioners and to students fo medicine.

A RELIC OF THE JAMESON RAID:

EXTRACTION OF BULLET AND SEQUESTRUM FROM THE UPPER THIRD OF THE THIGH TEN YEARS AFTER THE INJURY.

BY HENRY CURTIS, B.S. LOND., F.R.C.S. ENG.,

SENIOR ASSISTANT SURGEON, METROPOLITAN HOSPITAL, LONDON, N.E; ASSISTANT SURGEON, SEAMEN'S HOSPITAL SOCIETY; JOINT TEACHER OF OPERATIVE SURGERY AT THE LONDON SCHOOL OF CLINICAL MEDICINE.

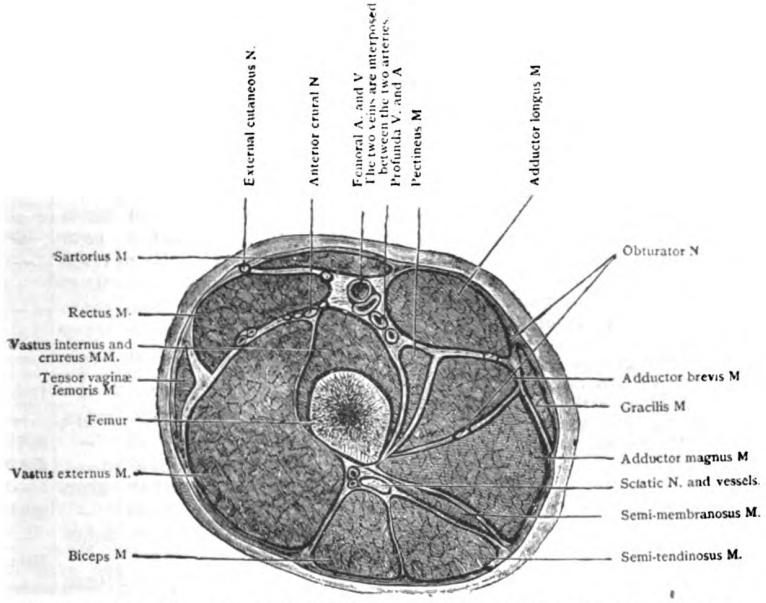
THE following notes of the extraction of a soft-nosed Mauser rifle bullet, and a sequestrum, from a wound in the upper third of the thigh ten years after the injury during the Jameson Raid may be of interest.

The wound was inflicted on Jan. 2nd, 1896, and before entering the outer side of the right thigh the bullet was said to have struck a clasp knife hanging from the belt of the patient, a farmer, aged 30 years at the time he came under my care at Bulawayo on April 8th, 1906. Two medical men at Krügersdorp, who operated at the time, informed the patient that no bullet was recovered. The wound healed by March, 1896.

At the end of 1904 and the beginning of 1905 severe right-sided sciatica confined the patient to bed for 13 weeks, and during October and November, 1905, he was unable to get about owing to severe neuralgic pains in the right groin and all down the thigh. Indeed, ever since the wound "the leg had always troubled the patient, and after much exertion gave the sensation of being asleep." In 1906, at the end of February, the wound broke open for the first time and commenced discharging pus. On March 22nd, at Salisbury, Rhodesia, two medical men examined and explored the wound, which was situated on the antero-external aspect of the upper third of the thigh. They followed the sinus-like track for about six inches or more in a direction downwards and inwards, and not locating the bullet concluded that it might be in the lower fourth of the inner side of the thigh. The X ray installation at that time being unavailable they were under the greatest disadvantage, and for this reason the patient was sent to me at the Bulawayo Hospital, where at this time, by an unfortunate coincidence, our own apparatus happened to be almost useless.

Coming under my care on April 8th, 1906, 17 days after the previous exploration, the right thigh was seen to be much wasted, doubtless from disuse. At the antero-external aspect in the upper third of the limb there was an elongated depression, on the floor of which was the opening of a discharging sinus. The sinus was directed at first across the thigh, apparently towards the postero-external aspect of the femur, and then passed downwards and inwards. No foreign body or actual bare bone could be detected. The attempt to obtain a skiagram was most unsatisfactory, the only result being a very faint and ill-defined blur, but as this was the only hint available, it was assumed to indicate the presence of the bullet—a very fortunate assumption as it proved. It appeared to be situated rather to the inner side of the femur, just below the level of the sinus seen on the outer side of the thigh. This, of course, was contrary to what had been suspected, and it was quite impossible to guess whether it was on the inner or outer side of the linea aspera, a point of practical importance, when the attachment of the muscles is remembered, in determining whether the incision should be from the anterior or posterior aspect of the thigh. Fig. 1, from Sir William MacCormac's "Surgical Operations," will serve to emphasise the importance of this point by illustrating the relations of the parts, and will facilitate the following description.

Operation.—This was undertaken on April 19th, 1906. Deciding to examine the linea aspera at its inner edge, where it gave insertion to the tendon of the adductor brevis, the anterior incision was selected; and failing to find the bullet here, or from this position to get evidence of its presence on the postero-external aspect of the bone, it was intended to make a fresh incision on the back of the thigh between the vastus externus and the biceps.



With the thigh flexed and a little everted, as for ligature of the superficial femoral artery, a 3½ inch longitudinal incision was made along the anterior aspect of the thigh in its upper third, so that its centre corresponded with the apex of Scarpa's triangle, formed by the crossing of

the inner border of the sartorius over the outer border of the adductor longus muscle, about four inches, that is to say, below Poupart's ligament. Having exposed the pectineus and adductor longus muscles forming the inner portion of the floor of the triangle, and leaving the femoral vessels undisturbed to the outer side, the outer border of the adductor longus was defined and well retracted, thus bringing into view, between it and the pectineus, the adductor brevis. Following this muscle towards its insertion and well retracting, exploration soon revealed, deep down, at the back of the inner aspect of the femur, the object of our search, the Mauser bullet, which, mushroomed at one end, was then extracted. It presented the appearance shown in the accompanying reproduction of a photograph (Fig. 2), in which it is shown of the exact size. For this and the next picture I have to thank the hospital secretary, Mr. H. W. Garbutt, the patient naturally desiring to keep the bullet itself as a souvenir. The anterior wound and the sinus externally were drained.

Five days after the operation the pus became so offensive as to suggest the presence of necrosed bone, the temperature having risen to 102° F., as it had previously done four days before the operation. The temperature then steadily fell to normal, but 17 days after the operation, with a temperature of 100·6°, a great deal of pus escaped from the dressings, and both drainage-tubes were re-inserted. Six days later, on May 12th, a large sequestrum was removed through the external wound, derived from the anterior surface of the femur. This is shown in Fig. 3. The position of the sequestrum indicated the course of the bullet, which must have struck the femur from the outer side near its anterior surface and then slipped, or wandered subsequently, into the inner aspect of the femur, in close contact with the inner lip of the linea aspera. The patient must be congratulated upon the fact that the femoral vessels and their branches were so skilfully eluded by the bullet during its course and subsequently. Very offensive pus escaped from the wound next day, but the discharge soon ceased to be so, and greatly diminished in quantity. On June 1st, after a fortnight of normal temperature, with still occasional sharp attacks of sciatica, the patient returned home with the wounds nearly healed.

The following give the approximate measurements:—Bullet: length, 2·5 cm. (1 inch); diameter, shortest, 8 mm. ($\frac{3}{10}$ inch); longest, (where fungated) 1·7 cm. ($\frac{3}{4}$ inch). Sequestrum: length, 2·2 cm. ($\frac{9}{10}$ inch).

The sequestrum. (Exact size.)

THE GEOLOGISTS' ASSOCIATION.—The Geologists Association of London held their Easter excursion this year in North Devon with Barnstaple as the headquarters. The visitors were about 50, and included Professor W. W. Watts, F.R.S., President of the Geological Society; Dr. J. Evans, F.R.S., of the Imperial Institute; Dr. A. Smith-Woodward, F.R.S., British Museum. A very successful meeting was held, the places visited including Bideford, which has a museum with several interesting geological specimens, Lynton and the Valley of Rocks Abbotsham Cliffs, Instow, &c.

NOTES ON THE USE OF ADRENALIN CHLORIDE IN THE TREATMENT OF PLAGUE.

BY E. N. THORNTON, M.R.C.S. ENG., &C.,
ADDITIONAL MEDICAL OFFICER OF HEALTH FOR CAPE COLONY; LATE DISTRICT MEDICAL OFFICER, GUJRAT, PUNJAB.

IN the course of an outbreak of plague at East London in March, 1905, Dr. Barcroft Anderson suggested to me that adrenalin chloride might be given a trial at the local plague hospital. At this time we were not aware that the drug had been recommended for the treatment of plague in 1904 in India by Rai Bahadur Kailaschander, I.M.S., who, in an Indian medical journal, stated that while he considered it to be a sovereign remedy for bubonic plague, it was useless in other forms of the disease.

Dr. Anderson made the suggestion as the result of a number of post-mortem examinations, at which he had been struck by the extreme congestion of the organs of the bodies examined, which is so typical of plague. He thought that if a vaso-constricting drug were exhibited this general congestion might be prevented with much advantage to the patient, and adrenalin chloride naturally suggested itself to him, as, besides constricting the peripheral blood-vessels, it is a powerful cardiac stimulant.

The pathological changes found in the suprarenal glands themselves in fatal cases of plague were remembered, and it was thought that these changes might perhaps alter for the time being the normal action of the glands. The changes in the appearances of the suprarenals are not, so far as I am aware, described in any text-book or article on plague, but they were first pointed out by Dr. A. J. Gregory, the medical officer of health of Cape Colony, and have been recognised for a long time by plague medical officers in South Africa, and, indeed, have come to be regarded as one of the most striking appearances to be looked for at post-mortem examinations. In plague these glands are invariably found enlarged and extremely congested, if not actually hæmorrhagic. It is well known that removal of the suprarenals in monkeys is always fatal, death usually taking place within a period of 24 hours after the operation. Almost immediately after the operation the blood pressure falls, the animal becomes lazy, feeble, and lethargic, and dies from heart failure. Now, in plague it is also essentially the circulatory system that is almost at once profoundly affected by the disease, and it was suggested that this might be due in some measure to pathological changes occurring in the suprarenals.

On the administration of the drug in the first few cases in which it was tried the results were sufficiently satisfactory to ensure that all future cases admitted during the outbreak should be treated in the same manner. The East London outbreak, however, came to an end before a definite opinion, based on statistical data of any value, could be expressed as to the treatment, but in 1907, during an outbreak at King William's Town, I was afforded an opportunity of treating with it a further series of cases, bringing the total number of consecutive cases treated by this method up to 50. Dr. Anderson and I have since waited in vain for an opportunity to treat further cases, but the disease is now evidently eradicated from the colony, and therefore it would appear desirable to publish the results, in the hope that the method of treatment may be afforded extensive trial elsewhere, especially as all other methods, including the inoculation of patients with sera, have been discouraging.

Every case coming under Dr. Anderson's or my own treatment since March, 1905, has been placed on adrenalin, no matter what the condition was on admission, and, indeed, a large percentage of the cases were in a desperate condition at the time of admission, some being actually moribund, or practically so, and consequently hopeless cases from the first.

For adults 30 minim doses of Messrs. Parke, Davis, and Co.'s solution of adrenalin chloride of a strength of 1 in 1000 were at first usually given by the mouth, with 10 minims of tinctura strophanthi four-hourly for the first three days and three times a day thereafter for approximately another 14 days. Later, especially if the patient was extremely ill on admission, it was usual for the adrenalin to be given hypodermically or intravenously, in somewhat smaller doses until the patient was out of danger, when it was given, as in the earlier cases, by the mouth. The mixture for oral administration was made up as required, for it does not keep. In the worst bubonic cases it was usual to commence the treatment by injecting 20 minims of the adrenalin chloride solution in the neighbourhood of the buboes, especially where the buboes were unusually painful or where much extravasation was occurring into the surrounding tissues. The axillary cases particularly (where there are usually extensive serous effusion and hæmorrhagic extravasation involving the axilla, arms, and ribs) appeared to benefit from injections into the neighbourhood of the bubo, and in these cases much of the usual extravasation was prevented.

* E. = European; C., Coloured; N., Native. † B. = Bubonic; P., Pneumonic.

Remarks.—Case 1: In a collapsed condition on admission but quickly rallied.—*Case 2:* On admission patient not expected to recover but

gradually rallied.—*Case 3:* Uneventful recovery.—*Case 4:* Considerable extravasation round left femoral bubo; uneventful recovery.—*Case 5:* On admission patient delirious; slow recovery.—*Case 6:* An unusually severe case but quickly responded to treatment.—*Case 7:* Patient very delirious on admission; quick recovery.—*Case 8:* Very ill on admission; quick recovery.—*Case 9:* Patient admitted in a delirious condition, quickly became comatose, and died on fourth day after admission.—*Case 10:* Uneventful recovery.—*Case 11:* Practically moribund on admission; rallied somewhat under treatment, but quickly again passed into comatose state, and died on the fifth day after admission.—*Case 12:* Moribund on admission; never rallied sufficiently to have a chance of recovery.—*Case 13:* Patient comatose on admission. Quickly recovered under treatment.—*Case 14:* Practically moribund on admission; never rallied.—*Case 15:* Uneventful recovery.—*Case 16:* Patient acutely ill on admission. Rapidly passed into septicæmic state and died on third day after admission.—*Case 17:* Uneventful recovery but convalescence somewhat protracted.—*Case 18:* Acutely ill on admission, but reacted quickly to treatment.—*Case 19:* Desperately ill on admission but quickly rallied.—*Case 20:* Uneventful recovery.—*Case 21:* Patient very ill on admission but quickly recovered from attack of plague but died on the twenty-seventh day after onset from valvular disease of the heart.—*Case 22:* Uneventful recovery.—*Case 23:* Recovered from mild attack of plague, but developed tubercular meningitis and died on the forty-second day after date of onset of attack of plague.—*Case 24:* Uneventful recovery.—*Case 25:* Patient admitted acutely ill with double cervical bubo; never rallied.—*Case 26:* Practically moribund on admission.—*Cases 27 and 28:* Uneventful recovery.—*Case 29:* Rapidly improved under treatment.—*Case 30:* Uneventful recovery.—*Case 31:* Moribund on admission.—*Case 32:* Acutely ill on admission; protracted convalescence.—*Case 33:* On admission patient in collapsed condition. Rapid improvement and quick recovery.—*Case 34:* Uneventful recovery.—*Case 35:* Practically moribund on admission.—*Case 36:* On admission patient had obscure intestinal symptoms, as well as an obvious attack of plague. Patient died from acute intestinal intussusception.—*Case 37:* Practically moribund on admission.—*Case 38:* Matron of the plague hospital; contracted disease from nursing Case 37. Disease was fulminating in type and patient rapidly became comatose and died.—*Case 39:* Uneventful recovery.—*Case 40:* Rapid recovery.—*Case 41:* Acutely ill on admission; rallied quickly under treatment.—*Case 42:* Responded quickly to treatment; rapid recovery.—*Case 43:* Desperately ill on admission; rapid recovery.—*Case 44:* Acutely ill on admission; uneventful recovery.—*Case 45:* Acutely ill on admission; rapid recovery.—*Case 46:* Uneventful recovery.—*Case 47:* Acutely ill on admission; rapid recovery.—*Case 48:* Moribund on admission.—*Case 49:* Patient desperately ill on admission but quickly improved under treatment; uneventful recovery.—*Case 50:* Uneventful recovery.

As soon as a patient had the drug administered the blood pressure was raised and the heart stimulated, and symptoms of threatening heart failure usually immediately disappeared. To some extent, also, the lethargy and weakness of the patients diminished under the treatment, but the drug did not appear to have any effect in quieting delirium or decreasing sleeplessness. When the latter symptoms were prominent sulphonal was usually administered in addition.

From Table I. it will be seen that out of the 50 cases there were 15 deaths, but one of the latter, Case 23, had recovered from his attack of plague, but had subsequently, before discharge from the hospital, developed tubercular meningitis and died on the forty-second day after the date of onset of his attack of plague. Another, Case 21, also had recovered from a mild attack of plague, but died in the plague hospital on the twenty-seventh day after the onset of this disease from valvular disease of the heart, the latter condition not appearing to be appreciably affected in any way by his attack of plague. Animals inoculated with material obtained from the buboes of Cases 21 and 23 while ill from plague died from plague, but those inoculated from these cases after death survived. Another patient—namely, Case 36—while suffering from a mild attack of bubonic plague, died on the seventh day of the disease from intussusception of the bowel. The latter case may, however, I think, be recorded as a death from plague, as the intussusception may have been caused by this disease, though from the patient's symptoms it would appear possible that he had had it prior to the date of sickening with plague.

Accepting 13 as the correct number of deaths from plague in this series, the death-rate from plague was 26 per cent. only, notwithstanding the fact that 3 of the cases who died were moribund, and 5 were practically moribund on admission. The summary in Table II. shows the race of the patients, the form of the disease, and the deaths.

TABLE II.

Race.	Bubonic.		Pneumonic.		All forms.	
	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.
European	17	1*	1	1	18	2
Coloured...	3	1	—	—	3	1
Native	24	7	5	3	29	10
All races...	44	9	6	4	50	13

* Child with intussusception of the bowel.

The higher mortality amongst the native patients was due to the fact that these included the eight patients above mentioned who were admitted in a dying or almost dying state.

The results in this series of cases compare favourably with those obtained in all previous cases of plague (excluding cases of septicæmic plague which, of course, were all fatal) treated in the colony by other means, as the following summary of such cases indicates:—

TABLE III.

Race.	Bubonic.		Pneumonic.		Both forms.	
	Cases.	Deaths.	Cases.	Deaths.	Cases.	Deaths.
European	259	55	15	12	274	67
Coloured	320	122	26	19	346	141
Native	226	85	43	27	269	112
Asiatic	42	26	5	4	47	30
All races	847	288	89	62	936	350

From this it will be seen that the hospital mortality from plague (excluding septicæmic cases) in those cases not treated with adrenalin has been 37·4 per cent., or excluding Asiatics 35·9 per cent., as compared with a mortality of 26 per cent. only amongst those treated with adrenalin. This lower mortality does not appear to have been due to the fact that the patients treated with adrenalin had the disease in an unusually mild form, for, if anything, they appeared generally to have been somewhat worse than are cases that usually come under treatment, especially those towards the middle and end of the series.

In all the fatal cases in which adrenalin chloride had been used the alterations in the post-mortem appearances were extremely marked, although they were only what could be expected after the use of a drug possessing in such a degree vaso-constricting properties. In nearly all cases in which the drug had been freely used there was a marked diminution in the usual congestion of the organs, no hæmorrhages or petechiæ, less effusions into the pleura and pericardium, less enlargement of the spleen and liver, and very little enlargement or alteration in the appearances of the suprarenal glands. In smears made for microscopical examination from such fatal cases as had been treated to any extent by the drug plague bacilli were found to be present in far fewer numbers than is ordinarily the case. Indeed, plague bacilli could not be found microscopically at all in smears made during the post-mortem examinations from certain of these cases, and more especially the pneumonic cases, although inoculated animals died from plague. Further observations are, however, required before this can be regarded as of constant occurrence. Assuming, however, that it is, a satisfactory explanation for it is not easy to find.

I am indebted to Dr. Gregory, the medical officer of health for the colony, for permitting me to publish these notes and affording me access to the official documents, and also to Dr. Anderson, who had a large proportion of the patients under his personal care.

Cape Town.

LONDON FIRES IN 1909.—Lieutenant Sladen, R.N., the Chief Officer of the London Fire Brigade, in his report for the year 1909 states that 103 persons, of whom 52 were children under 12 years of age, lost their lives in consequence of London fires. In 1908, 93 deaths were recorded. The total number of fires attended by the brigade during the period under notice was 3197. It is pointed out that a large number of fires occurs from easily preventable causes. In cases of fire delay is sometimes caused by persons using telephones asking to be connected with the nearest local station, and Lieutenant Sladen informs the public that the best method of calling the London Fire Brigade by Exchange telephone is, after getting communication with an exchange, to ask for "Fire Brigade," and on getting connected therewith to give the address of the fire.

BÁRÁNY'S NEW TUNING-FORK TESTS; WITH A FEW REMARKS.

BY E. CRESSWELL BABER, M.B. LOND.

LAST year Dr. R. Bárány showed at the Austrian Otological Society[1] a series of ingenious tuning-fork tests of his own devising. I had an opportunity of seeing some of these tests, not only at the International Medical Congress at Budapest, but also, through the kindness of Dr. Bárány, at the Clinic in Vienna. It is not possible in this article to describe them fully, but the following is a short account of them. To simplify the subject I have numbered them in the order in which Bárány has described them: (I.) Comparison of cartilaginous and mastoid conduction; (II.) new method of testing bone conduction; (III.) comparison between mastoid and tube conduction (an improvement and simplification of Rinne's test); (IV.) comparison between cartilaginous and tube conduction; and (V.) an improved method of performing Gellé's experiment.

I. *Comparison of cartilaginous and mastoid conduction.*—In the normal ear a tuning fork struck hard and placed lightly, without pressure, on the lower part of the mastoid, and afterwards held firmly up against the posterior surface of the auricle, is heard decidedly louder on the latter. In this case the result of the experiment is said to be positive (+). Closure of the meatus while the sounding fork is on the auricle increases the sound; the same occurs when the fork is held on the mastoid (Bing). The result of the experiment, therefore, remains the same. In middle-ear disease this experiment gives a negative (−) result. In very slight cases with middle and high tones there is often a positive result or the result is neither positive nor negative (+ −), but for the deeper tones (C) it is negative. Closure of the meatus makes it positive for all tones in slight cases. When there exists a moderate amount of middle-ear obstruction the experiment gives a − result to all tones, which becomes + on closure of the meatus. In marked middle-ear disease the result is − for all tones whether the meatus be open or closed. The reason for this is that in obstruction of the conducting apparatus the sound is almost always strengthened by closure of the canal when the fork is applied to the cartilage. When, on the contrary, the fork is applied to the mastoid, closure of the ear strengthens the sound only in slight affections of the middle-ear. In marked middle-ear disease the sound either remains the same or becomes less.

Another method of applying this test is as follows by means of an auscultation tube (otoscope). An auscultation tube is fitted into the ear of the patient and that of the surgeon, and the sounding fork is applied to the patient's auricle and mastoid. The sounds heard by the patient correspond exactly to those heard by the surgeon—e.g., if the fork is applied so that the patient hears it louder on the auricle, then the surgeon hears the same, and *vice versâ*. If this relationship is present with all forks then the least middle-ear obstruction may be confidently excluded. In affections of the middle ear the fork is heard by the patient louder on the mastoid, whilst the surgeon hears it louder on the auricle: i.e., the test is −. The greater the middle-ear affection, the more marked is this condition. In very slight middle-ear disease the patient hears the fork louder on the mastoid, whilst the surgeon hears it equally on the cartilage and mastoid. Precautions necessary in performing these experiments are: (1) That the tuning fork be applied to the lower part of the mastoid, as there is a place over the mastoid antrum where the experiment becomes − even in a normal ear; (2) that in applying the fork to the cartilage the latter be not so far bent forward as to close, or partially close, the ear; (3) that any contact of the fork (or hand holding it) with the auricle be avoided when the fork is applied to the mastoid; (4) that feeling the vibration of the fork on the cartilage be not confounded with hearing; and (5) it is of importance that the auscultation tube should fit air-tight in the ears, and that contact with the tube of the arm holding the tuning fork be carefully avoided. Bárány considers this a more accurate test than Rinne's, because in a large number of cases in which Rinne is + it gives a − reaction. It is said to be superior to Rinne in out-patient practice, as it deals only with gross qualitative differences, and is to a great extent independent of external noises.

II. *A new method of testing bone conduction.*—The auscultation tube being fixed in the ear of the patient and the surgeon, the tuning fork is placed on the mastoid of the patient. The exact point of application of the fork is of no consequence, though it is best applied far back to avoid the auricle; the amount of pressure applied is likewise immaterial. In a normal case the fork is heard equally long by the examiner and the examinee, but in some case the latter hears it longer. In disease of the middle ear a large number of cases hear it as long as, or longer than, the surgeon. In these cases Bárány thinks an affection of the nerve can be confidently excluded. In other cases, however, in which the usual tests show increased bone conduction, the new method gives a slightly diminished bone conduction. As Bing's experiments show, the closure of the meatus sometimes diminishes the sound in middle-ear affections. As soon, therefore, as the patient ceases to hear the fork Bárány removes the tube. In some cases the patient hears the fork again for a few seconds; as soon as this ceases the surgeon re-inserts the tube, but hears no sound. In these cases there is no disease of the internal ear. If, on the other hand, on re-insertion of the otoscope the fork is clearly heard, Bárány considers that a secondary affection of the internal ear may be safely diagnosed. In undoubted cases of disease of the internal ear it is always found that the patient hears the tuning fork for a considerably shorter time than the surgeon. Completes unilateral deafness cannot, of course, be diagnosed by thie method, as the good ear cannot be excluded, but in all these cases the patient reports diminished bone conduction in th; affected ear. The advantages claimed for this method are (1) That it is of no consequence at what point the tuning fork is placed; (2) that the same can be said of the pressure with which it is applied; (3) that the patient and surgeon are equally affected by external noises, and therefore independent of them (this does not seem to me strictly correct, because the unclosed ear of the surgeon is presumably normal, whilst that of the patient is often more or less deaf); and (4) that by this method it is probably possible to make a diagnosis of disease of the internal ear in many cases in which the old methods of testing showed exaggerated bone conduction.

III. *Comparison between mastoid and tube conduction (an improvement and simplification of Rinne's test).*—If an auscultation tube be fixed air-tight in the meatus of the surgeon and that of the patient to be examined, and the handle of a sounding tuning fork be placed alternately on the otoscope and on the patient's mastoid, in a normal ear or a purely labyrinthine affection the sounds heard by the surgeon and the patient respectively correspond exactly in intensity—i.e., if the observer hears the fork louder when it is placed on the mastoid than when it is placed on the tube, the patient hears the same and *vice versâ*. If the tones are so regulated that they are heard by the surgeon equally on the tube and the mastoid, they are heard similarly by the patient. (In order to diminish the sound on the tube the finger or the back of the left hand is interposed between the fork and the tube.) In affections of the sound-conducting media the patient hears better on the mastoid, while the observer hears better on the tube. If the middle-ear affection be very slight the predominance of sound to the patient on the mastoid only occurs when the two sounds are equal to the observer. (In such cases Rinne is always +, and on this account this experiment is considered more accurate than Rinne's test. In these cases interference with sound conduction was due to cicatrices, chalky deposits, or granulations on the membrane.) The greater the interference with the sound-conducting apparatus, the greater is the difference between the sensations of the examiner and examinee.

In maximal interference with sound conduction it is impossible with the strongest stroke of a fork pressed hard on the tube to make the patient hear it louder than when it is lightly placed on the mastoid.

IV. *Comparison between cartilaginous and tube conduction.*—In the normal ear the sensations of examiner and examinee correspond exactly. It is not very rare to find in disease of the conducting apparatus that the patient hears better on the cartilage, whilst the observer hears better on the tube. The cases in which this has been well marked have in Bárány's

[1] Monatsschrift für Ohrenheilkunde, Jahrgang xliii., Heft 5, p. 336; Ibid., Jahrgang xliii., Heft 6, p. 456; Ibid., Jahrgang xliii., Heft 8, p. 634.

experience hitherto been exclusively those of large perforations in the anterior inferior segment of the membrana tympani.

Experiments I. and III. have in a large number of cases given similar results; only in certain cases in which the cartilaginous conduction exceeds the tube conduction do differences occur.

V. *An improved method of performing Gellé's experiment.*—The two horizontal branches of a T-shaped rubber tube fitted with the usual nozzles are inserted air-tight into the meatus of the patient and the observer, and condensation and rarefaction of the air is effected through the vertical branch, either by the mouth or by a bag. Bárány recommends the former, as by this means the pressure can be very accurately regulated and both hands are left free. Condensation and rarefaction of the air give, according to Bárány, *exactly similar results*. Bárány's method of ascertaining that the otoscope is fixed airtight in the ears is as follows. After the nozzles are placed in position apply aspiration or compression to the vertical part of the T-shaped tube, when any entrance or escape of air is easily recognised by the observer's ear. *This method is employed in all the above experiments.* The tube used by Bárány has a short metal T in the centre, and exclusive of this measures in length about 22 centimetres in the patient's branch, 66 centimetres in the surgeon's, and 88 centimetres in the vertical branch.[2] In the first four experiments the end of the vertical branch of the tube is closed with the finger during auscultation. Bárány, so far as I gathered, uses in his experiments mostly a Politzer tuning fork, between d and e, 150 v.s., and in order to be able to institute a comparison I have used the same fork. It is advisable, in order to gain definite results, to keep to one fork at first so as to simplify the experiments as much as possible.

Remarks.—The above gives a short and possibly imperfect account of Bárány's tests, and there are a few other details which must be read in the original. It is obvious that it is impossible here to give an opinion of the practical value of the first four tests. A very large experience of several observers, combined if possible with pathological data, will be necessary to ascertain whether they are in any way superior to the tests already in use (Rinne, Schwabach). The advantages claimed for the tests have been pointed out; a few of what appear to me to be disadvantages may be noted.

In the first place, in Experiments I. and IV. we are using cartilaginous conduction, a method of conduction with the nature of which we are very imperfectly acquainted. In fact, Bárány uses the term "cartilaginous conduction" only as a convenient expression and without attempting to explain how the sound is conducted to the labyrinth when a fork is applied to the auricle. Again, the following experiment, which I have frequently performed, may affect the results of several of the above experiments. The auscultation tube being fixed air-tight in the ears of the surgeon and patient, and the open end of the third branch closed with the finger, the sounding fork is placed first on the mastoid of the patient, on the same side as the tube, and afterwards on the observer's mastoid as nearly as possible in a corresponding situation and with the same amount of pressure, and the two sounds, as heard by the surgeon, are compared. In the great majority of cases the sound is heard louder by the observer when the fork is *on his own mastoid*, and this is the case whether the patient's ear be normal or affected by middle- or internal-ear deafness. The accuracy of this observation is borne out by the fact that during the same experiment the patient, when he has a normal ear, will often tell you that he hears the fork louder on his own mastoid than when it is placed on that of the surgeon. My experiment (if confirmed by other observers) affects Bárány's method of testing the bone conduction (Bárány's Experiment II.); indeed, Bárány himself says that in some normal cases the fork is heard longer by the examinee. (See above under Experiment II.) It also has a bearing on Bárány's Experiments I. and III., making them more negative than they appear to the observer, unless there is a similar difference in the sound to the observer when the fork is placed on the patient's and on his own *auricle*, and when it is placed on the *tube* close to the patient's ear and to his own respectively. This is a point upon which I have not been able to satisfy myself.

[2] To be obtained of H. Reiner, Vienna, or Mayer and Meltzer, London.

Bárány's simplification of Gellé's test (Experiment V.) is, I have found, very practical. It enables pressure and suction to be accurately applied. I am able to confirm Bárány's observation that rarefaction and condensation of air in the meatus produce similar results in the great majority of cases.[3]

These experiments are highly interesting, and those connected with cartilaginous conduction will probably, as Bárány says, throw light on the physiology of the ear. They are well worthy of careful investigation, but they require very extensive application before their practical value can be accurately appraised.

In these remarks I have not gone into the question of the lateralisation of tuning-fork tests, which Bárány has treated in a more recent communication, nor into the use of other tests for distinguishing middle and internal ear deafness, such as Weber's test and examination with the scale of notes in cases of unilateral deafness.

Brook-street, W.

ARTHRITIS DEFORMANS.[1]

BY R. LLEWELLYN JONES, M.B. LOND.

WHILE deeply sensible of the honour, yet I must confess that it was with many misgivings that I acquiesced in your President's suggestion and consented to open a discussion before this society upon so obscure and intricate a subject as arthritis deformans. However, having had the temerity to essay the task I found myself forthwith confronted with the by no means trivial difficulty of deciding as to which aspect of this complex subject would most readily and most profitably lend itself to discussion. Upon reflection it occurred to me that I could not do better than select as the theme of my remarks the classification and differential diagnosis of the various joint affections grouped generally under the term "arthritis deformans." Doubtless, all of you who are familiar with the extensive literature will admit that much remains to be done before we shall be in a position to effect such a differentiation as shall lie beyond the reach of cavil. Our tardy progress towards this much-to-be-desired achievement may legitimately be referred in part to the bewildering state of our nomenclature.

This question of the terminology of chronic joint diseases is indeed one that clamours for speedy and careful consideration, if only with the object of ensuring a great measure of definitude in regard to the application of the various nosological terms. As matters stand, so numerous and so varied are the designations employed, and these withal are so vaguely defined, that not infrequently one finds the same term applied to denote wholly diverse joint affections, and *vice versâ*, identical arthritic conditions labelled by different appellations. Such indiscriminate application on our part of the various terms in use inevitably begets its own Nemesis in the shape of those mutual misunderstandings which so grievously hamper intelligent discussion, and for the same reason render perusal of the literature so laborious and but too often futile. Being, therefore, wishful, as far as possible, to obviate any confusion on this question of nomenclature, I would state that I use the term arthritis deformans in a generic sense, as covering all those various arthritic conditions to the discussion of which we are this evening committed.

Latterly the opinion has been steadily gaining ground that not one but several diseases have been included under one or other of the various terms used to designate collectively this class of joint disease. This view is, however, by no means as novel as certain writers on the subject are apparently inclined to consider, for they would appear to have overlooked the fact that even some years prior to the appearance of Charcot's classical monograph a German physician, von Volkmann, had clearly differentiated the anatomical lesions of rheumatoid arthritis and osteo-arthritis. Moreover, this contention of von Volkmann cannot be dismissed as mere

[3] I may mention that as long ago as 1881 I pointed out that the effect of condensation of air in the canal on the hearing of a tuning fork placed on the median line of the head was to diminish the sound in a normal ear. "Note on the Tuning Fork in the Diagnosis of Disease of the Ear," THE LANCET, April 9th, 1881, p. 577.

[1] A paper read before the Balneological and Climatological Section of the Royal Society of Medicine on March 9th, 1910.

speculative inference, for, as his writings demonstrate, he based his contention as to their fundamental distinctions upon the bed-rock of ascertained pathology as revealed to him in his anatomical researches. He was the first to establish the fact that in rheumatoid arthritis the initial changes began in the synovial membrane, the cartilages being affected secondarily. In addition, he noted the primary thickening of the periarticular and synovial tissues and the subsequent atrophy of the same, likewise the occurrence of fibrous and bony ankylosis. Furthermore, in his work he contrasted the features of this group with those of osteo-arthritis, of which he gave a classical description. It will be seen, therefore, from the foregoing details that the modern view as to the distinctness of rheumatoid arthritis and osteo-arthritis is, after all, but a recrudescence of that originally brought forward by Volkmann. With the advent, however, of Charcot's monograph on the subject the remarkable researches of Volkmann underwent an almost total eclipse. The great French physician, as we know, though he tacitly acknowledged the clinical distinctions of the two main varieties of arthritis deformans, nevertheless claimed that pathologically they were but different expressions or grades of the same underlying morbid process. So commanding was the personality of Charcot that this illustrious physician's conception as to the essential pathological unity of all forms of arthritis deformans dominated not only the French but most other schools of thought. Fortunately, however, the German school still retained their power of independent observation, and in the fulness of time von Volkmann's pioneer researches as well as his deductions were amply confirmed and reinforced by a series of anatomical investigations by different workers, among whom may be mentioned Hueter, Sameran, Waldmann, Hoffa, and Wollenberg.

Time does not admit of my alluding in detail to the post-mortem studies of the foregoing workers, and I must content myself with stating that the results of these and other workers' anatomical observations have largely determined me in regard to the classification I am about to submit to you of the various types of arthritis deformans. Under this title at least three distinct varieties of joint disease may be distinguished: (1) rheumatoid arthritis or atrophic arthritis; (2) osteo-arthritis or hypertrophic arthritis; and (3) infective arthritis.

With regard to the first-named division, *rheumatoid arthritis*, it may be mentioned that the synonymous term of atrophic arthritis was first introduced by Charcot, who noted in regard to one of his clinical types of arthritis deformans that secondary atrophic changes developed during the later stages of its life-history. This atrophy, he tells us, involved not only the skin, subcutaneous and muscular tissues, but even the bones; hence his suggestion that the name atrophic arthritis should be adopted as embodying the salient pathological characteristic of this variety. Recently, for the same reasons, the use of the term has been revived by Goldthwait, who would, however, restrict its application to the more chronic forms of rheumatoid arthritis. My clinical experience, however, accords with that of most English observers in that there is also an acute form of the malady to which the term under discussion is also applicable. Lastly, in addition to the foregoing acute and chronic types, I would also place under the same heading of rheumatoid arthritis that group of cases known as Still's disease. I do this provisionally, inasmuch as I have not on Still's basis of differentiation found it possible to effect a satisfactory discrimination between examples of this variety and cases of rheumatoid arthritis occurring in children. Briefly stated, Still claimed that this disease could be clinically differentiated from rheumatoid arthritis by the absence of glandular and splenic enlargement in the latter, and by the presence in rheumatoid arthritis of bony thickening and lipping. It is not, however, obvious how a satisfactory differentiation can be achieved upon these lines. Thus, rheumatoid arthritis, at any rate in its early stages, is not accompanied by bony outgrowths either in children or adults. Neither can any cleavage be upheld on the ground that lymphatic and splenic enlargement are absent in rheumatoid arthritis. For my own experience accords with that of others in that enlargement, at any rate of the glands, is frequent, while examples of splenic swelling are accumulating.

To my mind, too much stress has been laid on splenic and lymphatic enlargement as a differentiating factor, and pending positive bacteriological findings, I am inclined to regard Still's disease as a form of rheumatoid arthritis, in which the prominence of glandular swellings is to be accounted for as a peculiarity incidental to the early age of its victims, and that their presence cannot be construed as adequate evidence of its being a specific joint affection.

Passing now to consider the morbid anatomy of the above rheumatoid type, we are, I think, justified by recent anatomical researches in drawing the following conclusions:—1. The morbid process begins in the synovial and periarticular tissues, which undergo thickening and proliferation, but the cartilage, at any rate in the earlier stages, remains intact. 2. The changes that ensue in the cartilaginous and bony structures are to be regarded as secondary, and are predominantly atrophic in character. 3. In some cases proliferative changes take place in the bone and cartilages, but these occasional new bony outgrowths are inconsiderable in size. 4. Lastly, in the terminal stages of the disease secondary atrophic changes ensue. Thus the cutaneous and capsular tissues undergo progressive shrinkage; the joint cavity becomes obliterated with fibrous or bony ankylosis. This atrophic process involves also the shafts of the bones, the cortex becoming attenuated and the cancellous tissue replaced by scanty thin trabeculæ.

Before proceeding to consider briefly its clinical aspect, one may allude to the one salient characteristic of the etiology of rheumatoid arthritis—i.e., the frequency with which the disease is associated with, or arises in sequence to, affections of avowedly infective or toxic character; hence the strongest presumption of the malady itself being also of like origin.

From the clinical standpoint rheumatoid arthritis may be defined as a progressive polyarthritis, which runs a more or less acute or chronic course, diversified by remissions and exacerbations. The disease occurs chiefly in persons under 40 years of age, and is far more common among women than men, but in children, boys, if anything, are more frequently attacked than girls. It begins in the small joints, spreading centripetally, with a tendency to symmetrical distribution. The more exposed joints become the seat of smooth spindle-shaped swellings, due rather to periarticular thickening than to effusion, but no nodular outgrowths can be detected at the level of articulation. Eventually the enlarged joints undergo contraction or shrinkage, all the articular structures, skin, bone, cartilage, participating in this secondary atrophic change. The temporo-maxillary and cervical articulations are almost invariably implicated. Coincidently, severe wasting of interossei and extensor groups of muscles ensues, with marked exaggeration of the deep tendon reflexes. Enlargement of the lymphatic glands is not infrequent, while pigmentation, localised sweatings, and vaso-motor derangements are often striking collateral features. Cardiac troubles are rare. The temperature, when raised, is of low grade when compared with other arthritic affections, especially so when we bear in mind the widespread involvement of joints. The pulse-rate is frequently quickened, and this feature, when accompanied by pyrexia of low grade and persistent swelling, especially of swollen joints, is very suggestive of rheumatoid arthritis.

Considered briefly, the foregoing constitute the cardinal pathological and clinical features of rheumatoid arthritis, and we now pass on to consider the second group—*osteo-arthritis or hypertrophic arthritis*. From an etiological standpoint it contrasts with rheumatoid arthritis in that infective conditions do not appear to be so intimately related to its genesis, while, on the other hand, the influence of trauma, so inconspicuous in rheumatoid arthritis, is very much in evidence in osteo-arthritis. Additional factors are to be found—senility, arterio-sclerosis; and in those cases which arise so frequently at or about the menopause it is possible that its onset at this period may be determined by some modification in the internal secretions either of the thyroid, ovary, or both. As to its morbid anatomy, in this variety of arthritis deformans the essential anatomical lesions are those produced in the cartilaginous and bony structures, which undergo enlargement or hypertrophy. Most authorities now agree with Virchow that the synovial tissues are only involved secondarily. Histologically the ground substance of the cartilage undergoes a process of segmentation, while its cellular elements proliferate. Ultimately the cartilages by attrition become thinned, and their central portions, where pressure is greatest, being at length completely worn away, the denuded ends of the bones appear, and these subsequently become sclerosed and their surfaces eburnated.

On the other hand, the peripheral portions of the cartilage, not being subject to such pressure, instead of being thinned, become thickened, the proliferating elements forming irregular crests or nodules, which, primarily cartilaginous, ultimately become ossified. The osteophytic outgrowths thus developed are the source of the deformity of the affected joint and are responsible also for the limitation of its mobility, but although complete locking may occur bony ankylosis does not ensue.

The secondary changes in the synovial membrane have been specially studied by Hoffa, who distinguished two stages in their production. The first is characterised by villous overgrowth, proliferation of fixed connective tissue cells, with extensive pigmentary deposit. In the second phase degenerative processes predominate, the synovial membrane undergoing mucous changes and ultimately complete transformation into structureless hyaline tissue, a metamorphosis said by Hoffa to be pathognomonic of the affection. The excessive deposit of pigment noted by Hoffa is of great interest and may possibly possess some etiological significance.

Bowlby, as we know, has shown that intra-articular hæmorrhage can initiate osteo-arthritic changes in the subject of hæmophilia. Now it is quite possible that in many instances of osteo-arthritis a long-forgotten trauma may have supplied the initial impulse to the morbid process. Godlee has recently adduced some striking instances in which a joint injured in early life has in later years become the seat of osteo-arthritis. Such injuries, it is conceivable, might readily determine the occurrence of a greater or less degree of intra-articular hæmorrhage, which by its presence might initiate what might be termed a reactive osteo-arthritis. It is easy to understand how once started the morbid process tends to perpetuate itself; thus during the natural exercise of a joint so affected the roughened cartilaginous surfaces and bony asperities must be a source of continual irritation to the synovial membrane, which in its turn responds by new formation of connective tissue and hypertrophy of its tufts. Again, these elongated synovial processes, either by becoming free in the cavity or from time to time becoming incarcerated between the joint surfaces, contribute to its irritability, and a vicious circle is thus established. This hypothesis as to the *modus operandi* of trauma may account for the presence of the abnormal degree of pigment noted by Hoffa.

It will be convenient here to institute a comparison between the anatomical features of rheumatoid arthritis as opposed to osteo-arthritis. 1. In rheumatoid arthritis the initial changes are found in the synovial tissues; the cartilaginous and bony structures are only affected secondarily. 2. In osteo-arthritis, on the other hand, this sequence of pathological events is reversed, the primary alteration taking place in the bones and cartilages, the synovial membrane being only implicated secondarily. 3. The character also of the changes in the bone and cartilage differs in the two affections. Those in rheumatoid arthritis are retrograde and passive, while those in osteo-arthritis are active and proliferative. In short, atrophy of bone and cartilage is the distinguishing feature in rheumatoid arthritis, hypertrophy in osteo-arthritis. 4. Bony ankylosis occurs not infrequently in rheumatoid arthritis, rarely, if ever, in osteo-arthritis.

From the clinical aspect osteo-arthritis is essentially a disease of the middle and later period in life, being rarely met with under the age of 40 years. It affects both sexes equally. The mode of onset is usually insidious, and the course of the disease slow but progressive. Constitutional disturbance is slight; the temperature is not raised, the pulse not quickened, while pigmentation and trophic disturbances are generally absent. Muscular atrophy is slight. The articular lesions are but rarely generalised, the tendency of the disease being to involve but a few joints, and these not symmetrical, while it shows a predilection for the larger articulations. In these respects it contrasts with rheumatoid arthritis, which is polyarticular, symmetrical in distribution, with a marked preference for the smaller joints. Moreover, when the smaller joints of the fingers are attacked by osteo-arthritis the terminal phalangeal joints are the site of election, as opposed to the marked affinity displayed by rheumatoid arthritis for the mid-phalangeal articulations.

Local characters of the articular swellings will obviously be more easily studied in exposed articulations, by preference the mid-phalangeal. Unlike rheumatoid arthritis, when it affects the same articulations, the skin over the joints presents no abnormal features, and at no period does it undergo atrophic change. Marked swelling when present is due to synovial effusion and not to periarticular thickening; hence we get no spindle-shaped appearance. On the contrary, the outline of the joints instead of being smooth and rounded is broken and irregular, owing to the presence of bony outgrowths studding the line of junction of the articular ends. Displacement of the bones, when it occurs, is usually lateral in direction, and due directly to the mechanical thrust of the bony excrescences and not to muscular spasm. In rheumatoid arthritis, on the other hand, hyper-extensions and luxation are the rule, and for which muscular retractions are directly responsible. This diversity between the articular lesions of these two diseases becomes more pronounced in the later periods of their life-history; thus in rheumatoid arthritis the one-time voluminous spindle joints undergo progressive shrinkage, skin, bone, and cartilage tending to wither away, until eventually the articular structures dwindle into what Goldthwait has aptly termed the small end joint of rheumatoid arthritis. On the contrary, in osteo-arthritis the more ancient the lesion, the more massive the bony outgrowths, the more marked the enlargement of the affected articulations.

In concluding this brief account of osteo-arthritis one cannot help commenting on the paucity of its collateral phenomena, as compared with rheumatoid arthritis. This to our mind constitutes the salient distinction between these two diseases. Osteo-arthritis is much more a disease of joints, and joints only, than rheumatoid arthritis, in which the arthritic changes form only one feature in a very varied clinical picture.

It now remains for us to consider the third division—i.e., *infective arthritis*, for it cannot be doubted that examples of this nature intrude themselves into any category of arthritis deformans, however scrupulously compiled. These cases of infective arthritis have to be considered chiefly in regard to rheumatoid arthritis, more especially its acute forms, inasmuch as it is in connexion with them that confusion is most likely to occur. Before proceeding further it will, I think, be in the interests of lucidity if I preface my remarks by stating that I do not propose dealing with the differential diagnosis of those conditions reputed to be most frequently confounded with acute forms of rheumatoid arthritis. I refer, of course, to acute rheumatism, acute polyarticular gout, acute gonorrhœal rheumatism, and secondary syphilitic arthritis. Now with regard to all these joint affections, if we except acute gout, their association with a definite micro-organism has been more or less clearly established. Apart from these, however, there still remains a number of joint affections hitherto unaffiliated to any organism with which undoubtedly acute rheumatoid arthritis is very commonly confused. In this absence of any bacteriological findings we have to rely upon those clinical features which apparently distinguish acute rheumatoid arthritis from these non-suppurative types of infective arthritis. Unfortunately, nothing can be gained from the age incidence of these two varieties of joint disorder, for both occur at all periods of life, but something may be gathered from a marked predilection of rheumatoid arthritis for the female sex. In approaching the study of such cases the previous history should be carefully elicited, especially as regards the recent occurrence of some of the infective maladies known to be followed occasionally by non-purulent forms of arthritis, such as dysentery, typhoid fever, and so forth. If such be forthcoming it would constitute strong presumptive evidence that we are dealing with an infective arthritis following on one or other of these diseases rather than one of acute rheumatoid arthritis. Again, in the presence of local foci of infection, such as pyorrhœa alveolaris, otorrhœa, &c., it must not be too readily assumed that the joint condition is one of acute rheumatoid arthritis, for undoubtedly many of the instances of joint trouble occurring in such association are examples of infectious arthritis. But when, as too frequently happens, no past or present source of infection can be detected, reliance must be placed on the following characteristics. Thus in infective arthritis the constitutional symptoms are often much more acute, the temperature is of higher grade, and swelling of the lymphatic glands in association with the infected joints is almost invariable. The spleen is more commonly enlarged, while leucocytosis and a secondary anæmia are usually present.

As regards the articular lesions, though a large number of joints may be involved in infectious arthritis, in my experience such widespread invasion is not the rule. What happens in the majority of instances is that at the onset of the malady the disease attacks one, two, or three joints, and having done so shows no tendency to involve any other articulations, even though weeks or months may have elapsed during which the temperature may have been more or less continuously raised. Now had the condition been one of acute rheumatoid arthritis it would by that time have implicated all or a large number of articulations.

Again, the mode of distribution differs; in infectious arthritis the large joints are by preference attacked, though I have known exceptions to this rule in the case of the small joints of the hand; in rheumatoid arthritis the disease almost invariably begins in the smaller joints. Again, in infective arthritis the joint lesions show no tendency to symmetrical involvement, contrasting with rheumatoid arthritis.

With regard to the character of the articular lesions, nothing can be gleaned from their shape, for the spindle-shaped joints so frequently claimed to be pathognomonic of rheumatoid arthritis are exactly reproduced in cases of infective arthritis, when it attacks exposed joints such as the phalangeal. But the overlying skin in infective arthritis generally shows a definite red blush, whereas in rheumatoid arthritis it is unnaturally white or bluish in colour. Again, widespread inflammatory œdema of high grade is not infrequently present in infective arthritis, and forms a very valuable aid in differentiation.

Finally, apart from articular lesions we find in acute rheumatoid arthritis, as opposed to infectious arthritis, an abundance of collateral phenomena. Consequently in those comparatively rare instances of rheumatoid arthritis in which the disease remains for some time confined to the small articulations of the hand the following suggestion may prove helpful in distinguishing the case from one of infectious arthritis. If the opposite hand, hitherto unaffected by joint lesions, is found to be the seat of vaso-motor phenomena, neuralgic pains, or muscular cramps, the presence of such will be in favour of the condition being one of rheumatoid arthritis. While the foregoing, to my mind, constitute the chief points of distinction between these infective arthritides and the more acute forms of rheumatoid arthritis, it must be confessed that the dividing line is by no means sharply defined. In all probability a satisfactory differential diagnosis will not be available on purely clinical ground, but on bacteriological data, which it is hoped will soon be forthcoming.

Before concluding I would like briefly to discuss those particular points, considered by some to forbid any such sharp line being drawn between the rheumatoid and osteo-arthritic types. I refer, of course, to that very vexed question—namely, the exact significance of the new bony outgrowths occasionally met with in rheumatoid arthritis.

Some observers consider that the presence, even though occasional, of these minor bony proliferations negatives the possibility of any differentiation between these two joint diseases. Personally, I am not disposed to agree with this inference, for the following reasons.

It is generally admitted by most authorities that examples of rheumatoid arthritis classically complete in all their features are constantly to be met with in which no trace of bony outgrowths can be detected by skiagraphy. If this be granted, then it seems logical to infer that new bony formations cannot be regarded even as constant, much less as essential, characteristics of rheumatoid arthritis. In other words, the new bony outgrowths occasionally met with in this disease are secondary features or epiphenomena. As opposed to this, in osteo-arthritis the osseous proliferations, instead of being occasional, are invariable, and integral features in whose absence no diagnosis of the condition could be upheld. Again, the bony outgrowths themselves differ widely in the two diseases, being inconsiderable and spicule-like in rheumatoid arthritis, but massive and rounded in osteo-arthritis.

As to the exact nature of these minor bony proliferations in rheumatoid arthritis, I am not disposed to agree with those observers who would construe such as evidence of the transition of a condition of rheumatoid arthritis into one of osteo-arthritis, but would submit that they allow of a different explanation. Thus the morbid process in the articular ends in rheumatoid arthritis is one of rarefaction and softening. Consequently it follows that by reason of this pathological change these structures are peculiarly susceptible to stresses and strains; in other words, the ends of the bones tend to undergo plastic adaptations in their shape as a result of the retraction of the skin and pericapsular tissues, aided by the pull of the related muscles. From a consideration of X ray photographs I am inclined to think this forms a reasonable hypothesis as to the factors responsible for the altered shape in the ends of the bones. Again, Hoffa, in discussing this question, states that the bony proliferations in rheumatoid arthritis, when they occur, are in proportion to the amount of atrophy that has occurred, and he would regard them as reparative in nature. Now were the proliferative changes in rheumatoid arthritis of the same nature as those of osteo-arthritis, one would expect that their size would be in relationship to the duration of the disease. On the contrary, it would appear from the anatomical researches of Müller, Kachel, and others, that notwithstanding the existence of the disease for prolonged periods, in one instance for over 20 years, bony outgrowths were absent, whereas in other of much briefer duration slight bony proliferations were present.

Approaching this vexed question now from the clinical standpoint, it does not appear to me that the existence side by side, in the same patient, of rheumatoid and osteo-arthritic lesions can be construed as evidence of their identity, or that one condition passes into the other. It is certainly true, as McCrae and others, including myself, have observed, that in any given case, while some of the joints may be of a rheumatoid type, other articulations in the same individual may be of osteo-arthritic character. But such instances of the overlapping of the two varieties are comparatively rare, and, as Goldthwait, in discussing this point, contends, the articular lesions can usually be discriminated by their onset at different periods of the patient's life and by their distinctive and widely differing characters.

We have an analogy in the case of gout and osteo-arthritis, the lesions of which, as Hilton Fagge demonstrated anatomically, are to be met with in different joints of the same individual. We do not in this case therefore presume that gout and osteo-arthritis are one and the same disease, or that they graduate one into the other, because they occasionally co-exist in the same patient.

Finally, in order to settle this vexed question more speedily, it is highly desirable that pathological investigations should go hand-in-hand with careful observations, as it is this lack of associated action on the part of the pathologist and clinician that has led us for so long erroneously to identify these two fundamentally distinct joint disorders, rheumatoid arthritis and osteo-arthritis.

Medical Societies.

MEDICO-LEGAL SOCIETY.

Deodands.—Malpraxis in Ancient Law.

A MEETING of this society was held on March 22nd, Sir JOHN TWEEDY, the President, being in the chair.

Dr. W. WYNN WESTCOTT read a paper on Deodands. Traces of the custom of declaring an animal or an inanimate object which had caused a death to be forfeited were, he said, to be found among many ancient peoples. In England, Bracton, who lived about 1250, wrote: "Omnia quæ movent ad mortem sunt deodanda" ("All things which lead to a death are forfeit to God"). Curious distinctions were sometimes made; for example, if a moving horsed carriage caused the death of a man both horse and carriage were deodand, but if a man fell from a wheel at rest the wheel only was forfeit. If an infant under the age of discretion was killed by a fall from a cart in motion no deodand was due, the infant not being a reasonable creature. In early days the forfeited animal or object or its value was delivered over to the priesthood, but later, when the king became more powerful, the forfeit went to the Crown as compensation for the loss of a subject. This procedure continued until the abolition of deodands in 1846. It was of great interest to note that this was contemporaneous with the passing of the law commonly known as Lord Campbell's Act for compensating the families of persons killed by accident.

Dr. H. OPPENHEIMER read a paper on Liability for Malpraxis in Ancient Law. From the earliest periods, he said, suffering humanity had been the happy hunting-ground of ignorance and imposture. It was not, therefore, extraordinary that from the dawn of civilisation legislators had found it necessary to safeguard the sick against ill-treatment at the hands of those who had undertaken to restore them to health and vigour. In ancient Egypt the theocratic form of government was evolved to perfection, and the practice of medicine was restricted to a class of priests who had made a study of the sacred books of Hermes and were bound to treat their patients according to the rules laid down therein. If they deviated from the law they did so at their peril. If whilst following the rules they did not succeed in saving their patients they were held free from all guilt; if, however, they deviated from the law and were unsuccessful they underwent capital punishment. As an example of the methods of treatment Aristotle said that the medical priests were forbidden to purge their patients before the fourth day of treatment. The harshness of the law was not so much due to solicitude for the patient as to anxiety to prevent sacrilege, for that was what breach of the rules amounted to, medicine being divine in origin and the sacred books having been inspired by Isis herself. In the ancient Chinese codes it was provided that where a doctor deviated from the established rules and practice, and thereby killed his patient, he should be held excused if it appeared to be simply an error, but should be obliged to quit his profession for ever. If, however, he intentionally deviated from the rules, and while pretending to remove the disease of the patient aggravated the complaint in order to extort money for its cure he should be punished as a thief. If the patient died the medical practitioner who was convicted of having designedly employed improper medicines or otherwise injured his patient was put to death by beheading. Here, then, as in Egypt, conformity to the traditional rules of practice was enforced, but as a legal and no longer as a religious duty. In ancient Persia malpraxis had a somewhat different significance: it meant unqualified practice, whether successful or unsuccessful, and it entailed the penalty of death by being cut in pieces. A candidate might try his skill upon the common people with impunity, but he could only treat a true believer, a worshipper of the sun, if he had passed the statutory tests. This was a delightful piece of class legislation in favour of the aristocracy; the same distinction between man and man was to be found in the laws of Hammurabi, king of Babylon. The code, which was the oldest in existence, contained the following provisions: 218. "If a surgeon has operated with the bronze lancet on a patrician for a serious injury and has caused his death, or has removed a cataract for a patrician and has made him lose his eye, his hands shall be cut off." 219. "If the surgeon has treated a serious injury of a plebeian's slave with a bronze lancet, and has caused his death, he shall render slave for slave." 220. "If he remove a cataract with the bronze lancet and made the slave lose his eye he shall pay half his value." In the Hindu law they found the same principles of class distinction, but here the extraordinary regard for all life which formed one of its tenets had triumphed over another fundamental principle, the caste system, for the ordinances of Manu laid down in quite general terms "all physicians and surgeons acting unskilfully in their several professions must pay for injury to brute animals the lowest, but for injury to human creatures the middle, amercement." In Greece liability for malpraxis did not exist. In Rome, wrote Paulus, he who "brings about the death of the patient is relegated to an island if belonging to the higher classes; but if of lowly rank he suffers capital punishment." This, however, only applied to intentional poisoning. In the earlier years the physicians were in the position of tradesmen of a low grade, but later, thanks to the influx of highly cultured Greek physicians, medicine was converted from a trade into a profession, and the practitioner became responsible for negligent treatment.

LIVERPOOL MEDICAL INSTITUTION.

Cerebro-spinal Rhinorrhœa.—Appendicitis.—Traumatic Neuroses.

A MEETING of this society was held on March 31st, Mr. G. P. NEWBOLT, Vice-President, being in the chair.

Dr. J. E. MCDOUGALL showed a case of Cerebro-spinal Rhinorrhœa of Spontaneous Origin. He said that the escape of the cerebro-spinal fluid from the cavity of the skull in fracture of the base was well known, but that its spontaneous discharge from the nose in the absence of injury was very rare. The patient was a man, aged 31 years, whose illness commenced at the age of 17 years with convulsive movements of the right arm and leg, with loss of consciousness. He had also severe frontal headache. The discharge of the fluid began nine years ago and persisted for two years. The present discharge had continued for 18 months; it was continuous day and night and averaged a little over a pint in the 24 hours. The nasal cavity was normal. The fluid gave the ordinary reactions of cerebro-spinal fluid.—Dr. T. R. GLYNN referred to a case of cerebro-spinal rhinorrhœa already published.

Mr. R. W. MURRAY read a paper on 151 cases of Appendicitis that he had operated upon during the last three years. He was of opinion that in the last 20 years the type of the disease had altered, and that the outstanding features of appendicitis as met with to-day were (1) the increased frequency of the disease; and (2) the increased virulence of the poison. He said that as soon as the diagnosis of appendicitis had been established arrangements should be made for an operation to be performed; the trouble was thus confined to the appendix and might be removed with the appendix. The risks attending an operation made under these conditions were known to be few; the dangers of delay were known to be many.—Mr. RUSHTON PARKER said that in some cases the appendix when removed showed no outward sign of disease, but on slitting it up a stricture or other alteration was found. Though early operation had often been justified by the discovery of even gangrenous change, yet sometimes the refusal to submit to operation had been followed by complete recovery and without recurrence. Again, symptoms of apparent recurrence due to adhesions and the resulting griping sometimes justified waiting, which was rewarded by recovery. At operations signs of spontaneous recovery had been revealed and amply explained the disappearance of large and indurated swellings; these were commonly noted in the pre-operation days. Even disappearance of the appendix by partial or extensive atrophy had been thus observed and might explain the impossibility of finding it during operation.—Mr. DAMER HARRISSON agreed in considering that the virulence of appendicitis was greater than formerly.—Mr. F. A. G. JEANS had met with two cases in which he could not find the appendix.—Dr. J. C. M. GIVEN mentioned two instances in which the patient was attacked with violent pains in the region of the appendix; both patients refused operation and were perfectly well in 36 hours.

Dr. T. R. GLYNN read a paper upon the Traumatic Neuroses and limited the term to neurasthenia, hysteria, and hystero-neurasthenia. He gave an historical review of the progress of knowledge on these states, mentioning the work of Erichsen, Oppenheim, Charcot, Thomsen, Russell Reynolds, and Page. He considered that predisposition from inheritance or habit was of great importance, and discussed the relative effect of physical and emotional shock. He instanced a number of examples from his personal experience and found that a hystero-neurasthenia was the most common form of the neurosis. He described in some detail the symptoms of the several varieties and laid stress upon the period of premeditation before the advent in full force of the neurasthenic symptoms. He contrasted the taciturn behaviour and gloomy appearance of the traumatic cases with the loquacity of the ordinary neurasthenic. Dr. Glynn considered the stigmata of hysteria, and was of opinion that these were rarely if ever simulated. He discussed the prognosis and showed a well-marked example in whom the symptoms had persisted for many years.—Dr. W. B. WARRINGTON said that he thought the historical method was the best way of studying this condition. He alluded to the possible organic nature of the symptoms in some cases. He instanced especially the severe symptoms following injury to the head without fracture of the bones, and mentioned that these had in some cases been correlated with small multiple vascular lesions. He also alluded to the development of a true traumatic myelitis, the symptoms appearing some time after the injury, and the lesion being of a very different nature to that of the ordinary system diseases. He alluded to the work of Babinski on the nature of the hysterical stigmata, but could not fully follow this distinguished French physician. Dr. Warrington touched upon

the effect of the law of compensation as affecting the development and influencing the course of these neuroses.—Mr. RUSHTON PARKER said that in cases of purely surgical interest malingering was common.—Dr. ALBERT E. DAVIS said that traumatic neurasthenia was, in his experience, rare. He regarded these states as largely due to unconscious suggestion on the part of the medical attendant and as closely allied to malingering. He attached the greatest importance to a thorough examination of the mobility of the spine. When this was perfect he was inclined to give a cheerful prognosis, and found that this was generally correct.—Dr. ROBERT STEVENSON made the important statement that in one firm where regular labour was employed, and in which the custom was to continue the full wage with easy work during the disability from an injury, neurasthenia had been unknown in ten years, whereas in another which employed casual labour and where the half-wage system and no work was adopted neurasthenia was very common.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.

Action of Radium on Tissues.—Ferric Chloride Reaction in Diabetes.—Exhibition of Specimens.

A PATHOLOGICAL meeting of this society was held on March 18th, Dr. J. B. HELLIER, the President, being in the chair.

Mr. A. S. F. GRÜNBAUM and Dr. HELEN G. GRÜNBAUM communicated some of the results of the action of Radium on Normal Tissues—viz., on skin from a human subject, and on the cells of the liver, gall-bladder, and stomach in monkeys. The skin was acted on for 5, 6, 24, and 30 hours respectively. The effects were those of gradually increasing inflammation with subsequent destruction of white corpuscles and apparent proliferation of the surface epithelium. The liver cells after an exposure of 19 days were affected only in the neighbourhood of the tube. The gall-bladder epithelium seemed quite unaffected, and the stomach epithelium was in one case replaced locally by fibrous tissue.

Dr. J. F. GASKELL read a paper on the importance of the Ferric Chloride Reaction in Diabetes. He said that the ferric chloride reaction in the urine could be taken as a measure of the acidosis present, when of mild degree. It indicated by the colour produced the amount of diacetic acid present. The β-oxybutyric acid, which could not be conveniently tested for, was roughly proportional to the diacetic acid present. Coma was always accompanied by a very deep colouration of the urine with ferric chloride. The exceptions found in the literature were of doubtful value. The appearance of the ferric chloride reaction was the signal that a benign case of diabetes had become a severe one, and that the tissue metabolism had become profoundly altered. In the early stages the patient was still amenable to treatment and might be reclaimed into the benign class, but if the reaction was strong treatment would only have a temporary effect in warding off the inevitable end. The direct change to a strict carbohydrate-free diet was both unnecessary and dangerous, as it often gave rise to a ferric chloride reaction when none was present, or increased one already existing. The more gradual reduction was just as efficacious and had not this objection. On these counts it was therefore very important to keep a close watch on this reaction, both as to its presence or absence, and also as to the depth of colour obtained. There was not at present a satisfactory method of influencing the production of acetone bodies. Baer and Blum had, however, in phlorizinised dogs got results by feeding with certain substances, which gave ground for the hope that such a result might be obtained.

Dr. J. KAY JAMIESON showed a specimen of Unobliterated Vitelline Duct, with Umbilico-mesenteric Band, in a full-time fœtus.

Various specimens were also shown by the PRESIDENT, Dr. G. W. WATSON, Dr. A. L. WHITEHEAD, Mr. GRÜNBAUM, Mr. H. SECKER WALKER, Mr. W. GOUGH, Dr. C. OLDFIELD, Dr. T. CHURTON, and Dr. MYER COPLANS.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Bronzing of Skin.—Pigmentation in Pernicious Anæmia.—Glycosuria following Graves's Disease.

A MEETING of this section was held on March 18th, Dr. W. G. SMITH, the President, being in the chair.

Dr. J. M. FINNY exhibited a case of Discolouration of the Skin in a lad, aged 17 years. The discolouration was very marked on the neck, trunk, genitals, nipples, and wherever there had been pressure or irritation, such as round the waist. Deep pigmentation had taken place wherever there had been a burn or sore. The knuckles were all very dark; but the face was very little affected. He thought it might have been the "dirt disease," but on applying a blister the epidermis was quite black when taken away, and was found to contain true pigment. Dark pigment spots were to be seen coming in the patch where the blister had been. The mucous membranes were very little affected except for a small spot on the lip and two lines on the palate. A number of white marks on the back showed spots which had been torn. The scars as well as the whole skin were perfectly soft. The boy had no symptoms of vomiting or fainting. He had improved in every way since coming into hospital, though his appetite was not such as they associated with a boy of his life. The kidneys were sound, and the blood count showed no great loss of red corpuscles; the hæmoglobin was 60 per cent.

Dr. T. G. MOORHEAD exhibited a young man who had been admitted to hospital in January last with the typical symptoms of pernicious anæmia. His red corpuscles were reduced to 480,000 per cubic millimetre and his hæmoglobin to 20 per cent., his index being, therefore, about 2. He had a slightly enlarged spleen. Now the red cells were 4,200,000 and the other symptoms had disappeared. The principal interest of the case was the association of pigmentation with pernicious anæmia, which was rare. The first reported case was as recent as 1907, since when only two other cases had been reported. In the case before them there were ink-like patches spreading from the lips on each side, principally where the cheek came in contact with the teeth, in addition to a certain amount of pigmentation on the inner aspect of the lips. In two of the cases previously reported Addison's disease was confirmed at the necropsy. It had been suggested that the use of arsenic might account for the pigmentation, but in the present patient arsenic had only been used for a week prior to the patient's admission. He had suffered from malaria in India a year before.—The PRESIDENT discussed the cases.

Dr. W. A. WINTER read a short account of a case of Glycosuria following Graves's Disease. The patient was a woman, aged 59 years, who had well-marked Graves's disease 10 or 12 years ago, and was recently admitted to Steevens' Hospital as a case of diabetes. No trace of Graves's disease remained except slight exophthalmos. She had not been treated for it, and her recovery took place nine years ago. The glycosuria was accompanied by all the symptoms of diabetes, the specific gravity of the urine being 1050 on her admission to hospital, while there was 6·5 per cent. of sugar present in the urine, which contained neither albumin nor diacetic acid.—Dr. H. C. DRURY said the case was the fourth recorded in Dublin, in addition to one under his own care. The condition had been considered a fairly rare one, but it would appear that it only required attention to be directed to it to show that it was not so uncommon as had been thought.—Dr. FINNY said the question as to whether the thyroid and pancreatic secretion depended on one another was a point of considerable interest. The general view of the association of glycosuria and Graves's disease was that it was a very grave complication.—Dr. W. R. DAWSON said he did not know that the occurrence of glycosuria in mental disease was on all fours with its connexion with exophthalmic goitre. In his experience the two forms of mental disease in which glycosuria was found were melancholia and chronic dementia, and it had been attributed to part of the general disorder of metabolism that took place in such cases. Glycosuria occasionally followed the administration of thyroid as a drug; that might possibly be correlated with its occurrence in exophthalmic goitre.—The PRESIDENT said

they must be aware of mistaking a coincidence for a true association. Glycosuria and albuminuria were frequently associated, and in true diabetes it was not rare for albuminuria to develop. There were, undoubtedly, a great number of carbohydrates which they could identify, and there were many varieties of proteins which they could not so easily distinguish. The result was that they had a larger book of scientific evidence in regard to the physiological chemistry of the carbohydrates than of the proteins. Still, the two conditions were liable to go together in clinical practice, and, speaking generally, the appearance of sugar in the urine was undoubtedly an example of a disorder of a metabolic function which could easily be upset by a great variety of causes. There were three broad groups of relationship between glycosuria and clinical medicine: first, with the nervous system; second, with the three ductless glands, the thyroid, the pituitary body, and the adrenals; and third, with the secretory glands; but there was also room for a small margin of cases referable to the kidney.

Dr. J. A. MATSON exhibited a case of Amyotrophic Lateral Sclerosis. The case was perfectly typical. The symptoms were first noted in October, 1908.

Dr. T. P. C. KIRKPATRICK gave an account of the Pioneers of Anæsthesia, and illustrated a very interesting communication by numerous lantern slides.

Reviews and Notices of Books.

The Open-air or Sanatorium Treatment of Pulmonary Tuberculosis. By F. RUFENACHT WALTERS, M.D., B.S. Lond., M.R.C.P. Lond., F.R.C.S. Eng., Physician to the Crooksbury Sanatorium. London: Baillière, Tindall, and Cox. 1909. Pp. 323. Price 5*s.* net.

IN this work Dr. Walters has given a full description of the methods of treatment employed in a good open-air sanatorium. It is intended for the use of physicians in such an institution or in private practice. The author very rightly points out that many people refuse to undergo systematic treatment for pulmonary tuberculosis until the disease is well advanced and correspondingly difficult to treat satisfactorily, partly because in the early stages of the disease the patient frequently feels fairly well, and partly because of an exaggerated idea of the discomforts of sanatorium life. A stay at the seaside or in the country is often substituted, and not infrequently harm results because the patient is ignorant of the fundamental rules of the life he should lead, and believes that he has only to walk about and eat large meals in order to become quite "cured." We agree with Dr. Walters that in dealing with intelligent patients it is a great advantage if the medical attendant can secure their coöperation by explaining the reasons for the treatment adopted. Further, many patients desire a reliable book suggesting how and where they should live on leaving a sanatorium, also the precautions which should be adopted to prevent infection.

Dr. Walters found it difficult for practical reasons to publish the technical and the non-technical details in separate volumes. He, therefore, combined them in one, the first part being concerned with matters which patients themselves should know, this at the same time forming a convenient summary for the practitioner, while the second deals with more purely technical matters. Sound advice is given as to the treatment in the patient's home. The whole life of a patient undergoing treatment for tuberculosis is carefully described, details as to rest, exercise, and diet being fully given. Dr. Walters takes a broad-minded view of the subject and consequently escapes many of the errors which other observers have fallen into. We think, however, he condemns too severely the method of taking the temperature by the mouth. It has been conclusively proved that for all practical purposes the oral temperature may be relied upon, and equally good results are obtained in those institutions where this method is in use as in those in which the plan of taking the temperature in the rectum is in vogue.

We have read this volume with much interest and can recommend it to those of our readers who wish for full instructions on the sanatorium treatment of pulmonary tuberculosis. It will be noticed that in many particulars Dr. Walters's views are exactly endorsed in an interesting paper by Dr. Wethered which we publish in this issue.

Lehrbuch der Physiologie des Menschen. Herausgegeben von W. ZUNTZ und A. LOEWY. With 306 illustrations and two plates. Leipzig: F. C. W. Vogel. 1909. Pp. 763. Price 24*s.*

THE scientific reputation of the editors is a guarantee of the quality and up-to-dateness of their own contributions and those of their various collaborators. Amongst the latter are the well-known names of the veteran physiologist Exner of Vienna, Verworn, Cohnheim, Kreidl, and Nagel, each and all of whom have left their mark in the annals of physiological discovery. The lamented death of the genial and accomplished Professor Langendorff of Rostock delayed the issue of the work, but from his pen we have the excellent chapter on the Circulation of the Blood (46 pages), a concise epitome of the subject illustrated by many excellent, well-printed tracings of blood pressure. Of the 23 chapters into which the work is divided Verworn leads off with a short (16 pages) but terse account of General Physiology, much on the lines of his well-known standard work on this subject. Müller of Rostock deals with the Chemical Composition of the Body (24 pages) and with the Morphology and Chemistry of the Blood (45 pages). To Professor Weiss of Königsberg is entrusted the Physiology of Muscle and Nerve. Having regard to the value and importance of Einthoven's string galvanometer, it would have been well to give a fuller description of the instrument, a figure of the apparatus itself, and a typical tracing from a muscle or the heart.

In the 56 pages at his disposal Exner gives an excellent account of the Central Nervous System, a subject to which he has himself made very considerable contributions, and we are glad to see an account of hypnosis and an nstantaneous photograph of Czermak's experiment on a crayfish. Professor Kreidl of Vienna deals with the Cranial and other Nerves, and also with hearing and voice and speech (16 pages). The senses are distributed as follows: general physiology and special physiology of the lower senses—smell, taste, temperature, pain, pressure, motion, and position—to Nagel of Rostock (34 pages); and vision to Schenck of Marburg (59 pages). The account of the senses is specially full and illuminating—not of course nearly so full as the same authors have contributed to the "Handbuch der Physiologie," now being edited by Nagel. Du Bois Reymond deals with the Mechanism of Bodily Movement (17 pages), a subject rather apt to be neglected in modern text-books, but withal one of exceeding practical importance and daily interest. He also gives a very readable account of the innervation of the respiratory apparatus. The Chemistry of Respiration is discussed by Johannson of Stockholm, who has devoted much attention to this subject. Spiro of Strasburg treats in an adequate manner Lymph Absorption and Assimilation, while to Ellenberger and Scheunert of Dresden is assigned Digestion (78 pages). Starling's work on the "law of the intestine" should have been more fully gone into and illustrated by means of a figure or two, and we should have welcomed the insertion of the appearances in the intestine, as shown by the bismuth nitrate and X ray method. Perhaps in the next edition a figure of the complex systems of nerves distributed to the

abdominal and pelvic viscera may be added. In any case it is much required. Metzner of Basle has congenial subjects in the Excretions of the Skin and Internal Secretions. The latter subject is very fully gone into and is well illustrated (47 pages). The spleen, however, is very summarily dealt with, and there is no figure of a plethysmograph or record of its rhythmical variations in volume. To the Urine and its Secretion 23 pages are contributed by Cohnheim of Heidelberg. Zuntz in about 50 pages deals in a broad and practical way with subjects with which he is specially conversant—viz., Metabolism and Heat—while his co-editor closes the volume with a short chapter on Reproduction and Growth.

The work does credit both to its editors and to their judicious selection of collaborators. After mature consideration it was decided to omit references to the literature of the various subjects. The book will prove a useful summary and exposition in a broad, practical form of the present state of physiological knowledge, and should be welcomed by all physiologists as well as by students of medicine.

Scientific Memoirs by Officers of the Medical and Sanitary Departments of the Government of India. No. 30. The Theory and Practice of Anti-Rabic Immunisation. By Captain W. F. HARVEY, M.B. Edin., I.M.S., and Captain ANDERSON G. MCKENDRICK, M.B Glasg., I.M.S. Calcutta: Superintendent of Government Printing, India. Price Annas 12, or 1*s.* 2*d.*

Captain W. F. Harvey and Captain A. G. McKendrick, the authors of this interesting issue of the well-known scientific memoirs by the officers of the Indian Medical Service, give us here the result of their investigations on rabies conducted during 18 months. The minuteness of the observations recorded testifies of itself to the arduous nature of the work undertaken. The first record deals with the infecting power of dried rabies spinal cords relatively to fresh rabies virus; the observers show that sharp differences in infectivity exist between fresh, one, two, or three day cords; that there is a difference of infectivity amounting to one-half between three and five day cords, whilst it is also evident that by the third day of drying the rabies cord has lost very much of its original infectivity; and, lastly, that there is an exceedingly gradual diminution in infectivity for five-day cord down to little or none in the nine-day cord. The authors then proceed to consider the rate of desiccation of rabies spinal cord by the ordinary procedure and its bearing upon the use of the cord for immunising purposes. It is seen that the loss of weight continues milligramme by milligramme for about 60 days, whilst with regard to the curve of drying compared with the curve of infectivity, the two curves show a very marked correspondence, so that it may be stated that the rate of loss of infectivity of rabies cord undergoing slow desiccation is directly proportional to the rate of loss of water contained in that cord; slow desiccation means death of the rabies virus, and, therefore, as they consider dead rabies virus to be comparatively valueless for immunisation, it may be held probable that the immunising power of a given portion of rabies cord is a function of the unkilled remnant of rabies virus which is contained in that cord. Next taking up the matter of massive doses of fresh fixed virus in anti-rabic immunisation, they give a table showing: (1) that massive doses of fresh fixed rabies virus may be given to certain animals subcutaneously without danger of infection, and (2) that a small number of inoculations, or even a single inoculation, of such material can confer immunity to subdural infection. The concluding portion of the memoir deals with the question of the existence of a rabies toxin, and as the result of their consideration the authors hold that there is no evidence for the existence of such toxin, whilst there is abundant evidence for the toxic action of foreign nerve material. Their final conclusion is that the quantity of living fixed virus and the duration of time of administration are the only points which need be considered in making out a scheme of anti-rabic treatment. In addition to the above points alluded to in this well-reasoned memoir we find the technique for the estimation of the salinity of small quantities of blood serum clearly given.

The volume indicates the good scientific work that is being done by the officers of the Indian Medical Service.

A Practical Treatise on Ophthalmology. By L. WEBSTER FOX, M.D., LL.D. London and New York: D. Appleton and Co. 1910. Pp. 807. Price 25*s.* net.

TEXT-BOOKS of ophthalmology may be divided into three classes—viz., manuals for elementary students, text-books for more advanced students, and exhaustive treatises designed for the use of specialists in the subject. Dr. Webster Fox's book belongs to the second category, which already includes the admirable text-books of Fuchs and de Schweinitz, the latter a practitioner in the author's own city of Philadelphia. It is a bold deed to enter into competition with Fuchs and de Schweinitz in a field which they have long held brilliantly against all comers. Dr. Webster Fox's great reputation both in his own country and in Europe marks him out as a worthy competitor. It remains to be seen whether his temerity is justified in the event.

The work displays no noteworthy originality of design. The usual method of treating the various sections of the subject, a method so obvious and logical that it is scarcely likely that it can be improved, has been adopted. The minor detail of treating optical principles and errors of refraction towards the end of the book is to be deprecated as eminently illogical. Two chapters on the ocular manifestations of general diseases hold out the hope of a useful addition to the ordinary scheme, but minuter investigation fails to justify their insertion, for they are too cursory and the information is too nebulous to be of much real service. A final chapter on laboratory "technic" falls under the same ban; it is futile to attempt adequately to cover the whole range of the technique of ocular pathology and bacteriology in less than 40 pages.

After a very short and superficial description of the development of the eye its anatomy is discussed. The designation of Bowman's membrane as elastic is only noteworthy as an example of not infrequent evidence throughout the book of archaic views now generally held to be disproved. "Sattler's layer or chorio-capillaris" on p. 16 is a little error which should be corrected in the next edition. The description of the external examination of the eye is too scanty, and is lacking in that method and precision which are so essential in teaching. Indeed, the book abounds with vague statements which cannot be condemned as inaccurate, but which require modification and explanation to make them of real value. In the chapter on the lids, however, no less than 16 operations for ptosis are described, and the operative treatment of entropion and ectropion receives almost equal attention.

The treatment of diseases of the lacrymal apparatus for the most part follows the lines of the older school of ophthalmologists. The statement that "extirpation of the sac is recommended as a last resort, but the difficulty encountered in performing this operation usually causes it to be changed into one of destruction by the use of caustic and the cautery" betrays a pessimism which will be generally regarded as unwarrantable. The chapters on diseases of the conjunctiva and cornea are detailed and accurate accounts. In dealing with the uveal tract two forms of "serous choroiditis" are distinguished, "one constituting acute inflammatory glaucoma"; this is a reversion to the pathology of Mackenzie's day, and is not the only example that might be quoted where the pathological teaching is weak.

There is much valuable information in this text-book for those who are qualified to read it in a critical spirit, but as a book for students it can be recommended only with reserve and not as a really successful competitor with the books already in the field. The printing and illustrations are good, though many of the latter are borrowed.

A Text-book of Experimental Physiology for Students of Medicine. By N. H. ALCOCK, M.D. Dub., D.Sc. Lond., and F. O'B. ELLISON, M.D. Dub. London: J. and A. Churchill. 1909. Pp. 139. Price 5*s.* net.

Professor E. H. Starling in the preface to this book states that London teachers have felt that the courses in practical physiology were unsatisfactory and did not meet the requirements of the medical student. The syllabus in the revised regulations of the University of London is, it appears, more in accordance with these requirements, and the present work is an attempt to put this syllabus into practice.

Apart from a description of the dissection of a rabbit at the beginning of the work, the course is divided into 37 lessons. Under the head of muscle four lessons are included, which deal with batteries, coils, keys, twitch tetanus, action of drugs, and electrical changes. To the circulation eight lessons are accorded, including the anatomy of the heart of a sheep, the arterial schema, instruments for studying the blood pressure and pulse, the plethysmograph and the capillary circulation, and experiments on the frog's heart. Under the heading "The Circulation in a Decapitated Animal" we find that "the animal is killed under chloroform or ether anæsthesia, and artificial respiration arranged by the demonstrator." On this animal the blood pressure is measured and the effects of adrenalin tested. The actions of the cardiac nerves are to be studied in the carcass of a decapitated cat. One lesson is devoted to vaso-motor nerves, the actions of the depressor and splanchnic nerves and asphyxia, while there are two demonstrations, one of vaso-dilator nerves in a dog and the other on the production of lymph.

Three lessons are assigned to digestion, and these include a demonstration on movements of the intestines. It does not appear whether the lesson on the innervation of the pelvic viscera is or is not a demonstration. Four lessons are devoted to respiration, and these are the only lessons which touch on chemical matters; two to the blood, including the blood gases. The secretion of urine is shown by two demonstrations, one for the act itself and the other for the influence of local vascular changes on the secretion, which, of course, includes recording the volume of the kidney.

One lesson suffices for temperature and heat production in man and mammals. To the nervous system four lessons are given, and these include electrotonus, tendon reactions, spinal reflexes, velocity of nerve impulse, and a demonstration on cerebral localisation. To the special senses are allotted six lessons on familiar lines.

We quite agree with the writer of the preface that "the student who has conscientiously worked through the exercises will find that the knowledge gained thereby will materially assist him in his future work—i.e., in the comprehension and treatment of disease." How many medical students in London, however, carry out such a full programme?

Allen's Commercial Organic Analysis. Fourth edition. Entirely rewritten. Edited by HENRY LEFFMANN, M.A., M.D., and W. A. DAVIS, B.Sc., A.C.G.I. London: J. and A. Churchill. 1909. Pp. 576. Price 21s. net.

WE feel sure that most analytical chemists will in one way regret that the march of events has necessitated the presentation of Allen's great work on "Commercial Organic Analysis" in practically the form of a new work. They will miss the familiar original volumes which contained such a store of valuable practical information on so many matters pertaining to commercial organic analysis. The identity of the old volumes is quite gone in the first volume now issued of the fourth edition. The printing is different, the paragraphing is different, and it is evidently intended to re-arrange and to re-entitle many of the sections. "Allen's Commercial Organic Analysis" is, in fact, to be in future a kind of international dictionary on the subject, the articles being contributed by a number of well-known writers on analytical subjects, who subscribe their names. Thus in the first volume are ten articles which comprise (1) preliminary considerations, by William Davis, B.Sc., as, for example, physical properties, action of solvents, the use of the spectroscope, and so forth; (2) the alcohols, by G. C. Jones, F.I.C.; (3) malt and malt liquors, by Julian L. Baker, F.I.C.; (4) wines and potable spirits, by G. C. Jones; (5) yeast, by Emil Schlichting; (6) neutral alcoholic derivatives, by Henry Leffmann, M.A., M.D.; (7) sugars, by E. Frankland Armstrong, D.Sc.; (8) starch and isomers, by the same writer; (9) paper and paper-making materials, by R. W. Sindall, F.C.S.; and (10) acid derivatives of alcohols, by Henry Leffmann. This list practically forms the contents page of the original edition. The original author himself, it appears, found that the work which he so ably started grew, as it was bound to grow with our advancing knowledge, too large to be managed by a single writer, and then his health broke down, which culminated in his death in 1904. This did not happen, however, before he had expressed his views as to the plan on which future editions should go. The present editors have met these views admirably; they have chosen the right workers and writers, and there is little doubt that the completed work will occupy, as it has always done, the first rank amongst the works of reference on laboratory manipulation in regard to commercial organic analysis. The task of completing eight volumes of the series is well in hand, for Vol. II. is already in the press, Vols. III. and IV. are about ready, and the remainder are promised as quickly as is consistent with good work. Analysts will be sorry to abandon the old familiar trustworthy volumes, but they will be amply consoled by possessing in the new all that is known up to the present date on the subject of accurate analytical methods applied to commercial organic products.

LIBRARY TABLE.

The Elements of Animal Physiology. By W. A. OSBORNE, M.B. R.U.I., D.Sc., Professor of Physiology in the University of Melbourne. Melbourne: T. C. Lothian. 1909. Pp. 152.—It is the aspiration of the author that his book may serve as a text-book intermediate between the primer and the special manual of human or veterinary physiology, and there fore be of use to students of medicine, veterinary science, and agriculture. As no presumption is made that the reader has studied chemistry or physics, the book may be read with profit by others who may not be entering upon a definite course of professional study. The author has selected the titles of his chapters as follows: Essentials of Life, Mammalian Tissues, Hormone and Nerve, Elements of Biochemistry, The Proteins, Enzymes, Muscle Heat, Nutrition, Digestion and Absorption, Blood Circulation, Respiration, Renal Excretion, Afferent Systems, Central Nervous System Reproduction, Lactation, and Ductless Glands. Most of the illustrations are taken from well-known text-books. The living moving cell is credited with "memory," and also with "intelligence." This is quite an elementary little book, which is certainly not nearly sufficient to meet the wants of the medical student in this country.

Aids to Microscopical Diagnosis (Bacterial and Parasitic Diseases). By E. BLAKE KNOX, B.A., M.D. Dub., D.P.H. (Honours), Captain, R.A.M.C.; formerly Assistant Lecturer in Pathology and Bacteriology, Trinity College, Dublin. London: Baillière, Tindall, and Cox. 1909. Pp. 156. Price 2*s.* 6*d.* net.—The title of this book does not quite cover the scope of its contents, for it deals with more than aids to diagnosis of disease by means of the microscope. The author has something also to say on the prophylaxis and treatment of bacterial and parasitic maladies, and in some instances he discusses their etiology and epidemiology. In his preface Captain Blake Knox very properly disclaims any idea of substituting his little volume for any of the excellent text-books on bacteriology, parasitology, or tropical medicine; rather does he present his work as one to be used by candidates with a view to revise the knowledge which they have already gathered from the recognised text-books before presenting themselves for examination. It is not to be used for cramming purposes, but for refreshing the memory of the candidate. We do not quite understand the author in his reference to the incubation period of plague. There are several misprints—e.g., on p. 95, alluding to inoculation as a channel of infection, "scratches and post-mortem accidents have also proved this, and that the period of incubation is about 14 days (shortest 2 days, longest 10 days)," where "14" should be "4." Nor do we accept without qualification the general statement that the case mortality rate of the bubonic form of plague is approximately 75 per cent. No doubt among Hindus this may be the rate, but outside India, and especially among the more resistant white races, the case mortality from that form of plague is considerably lower. The author modestly calls his book a compilation of notes taken in the laboratories of distinguished teachers for whose original ideas and methods he records "an acknowledgment of appreciation." We think that Captain Blake Knox's "Aids to Microscopical Diagnosis" will be found quite useful for revising purposes by those who are about to offer themselves for examination.

Therapeutic Agents of Bacterial Origin.—Messrs. Allen and Hanburys of 7, Vere-street, London, W., have issued recently two small publications which will be found interesting and serviceable by our readers. The first publication deals with the tuberculins and their uses as diagnostic and curative agents. The chief varieties in regard to both diagnostic and curative tuberculins are summarised, and their application is subsequently described. In the second publication there are useful notes on therapeutic sera, bacterial vaccines, and calf vaccine lymph. The notes are issued under the authority of the governing body of the Lister Institute of Preventive Medicine. The application of the various vaccines and their indications are clearly described.

The Prayer Quest: A Physiological Extension. By W. WINSLOW HALL, M.D. Edin. London: Headley Brothers. 1910. Pp. 144. Price 2*s.* 6*d.* net.—Dr. Winslow Hall's little book is devoted to the thesis that prayer is the most important business of life, and he has achieved a success in setting forth his views that prove them to be born of stronger stuff than pietistic emotion. His full appeal will only be to the mystic, but minds of widely different convictions may find much to admire, perhaps to envy, in the enthusiasm and boldness with which Dr. Hall describes the happiness he has found in a certain way of life and of thought, for by the "Prayer Quest" he includes a great deal besides the actual petitioning of God. Professor James, in his monumental analysis of the varieties of religious experience, dwells upon what he calls the religions of optimism, and in this category we must rank the faith here presented. Sect, even creed, is kept out of the book, although its perusal has left us with the impression that its writer could subscribe to the opening sections of a more famous "Religio Medici." At any rate, like Sir Thomas Browne, he has proved himself to have no part in the "general scandal" of his profession. We think his attribution of ill-health to neglect needs qualification, and surely lack of bodily efficiency can only sometimes be considered blameworthy. The book is composed in forcible and well-knit language, and the occasional verses need no apologetic epilogue. We could wish, however, that Dr. Hall would find substitutes for such substantives as "boon," "motive," "sense," and "lamp" when used in the sense of active verbs, and we protest strongly against the verbs "evolute" and "inkle." But in spite of these lapses the poet's touch is revealed.

Girl and Woman. By CAROLINE WORMELEY LATIMER, M.D., M.A. London and New York: D. Appleton and Co, 1910. Pp. 331. Price 6*s.* net.—The subtitle of this work is "A Book for Mothers and Daughters," and except as regards a few points we can warmly recommend it. It is written in clear, simple language, it is not faddy, and its author is evidently a sensible woman who knows what she is talking about. Dr. Latimer deals in the main with the transition period between girlhood and womanhood, and her first three chapters are concerned with the physical, the mental, and the moral disturbances of this period respectively. The two next chapters deal with reproduction and menstruation, and Chapter VI. with sexual knowledge. The remaining five chapters are upon various points of hygiene. The chapter upon the reproductive process is well done in accordance with Dr. Latimer's view that "for a girl to grow up uninformed of these facts and of the natural laws connected with them is doing her a great injustice, because she then enters life unprepared for some of its most serious problems. ..... Our present custom of surrounding all matters of sex and of reproduction with an atmosphere of mystery is a most unfortunate policy." And this brings us to the one portion of the book with which we disagree—namely, the chapter upon sexual knowledge. Here Dr. Latimer says: "No suitable source of information is open to a girl if her mother fails her"; and again "school instruction, no matter how good, can never take the place of a mother's influence in such matters." Instruction and influence, by the way, are two quite different things. In our opinion, it is better that sexual matters should be treated at school by means of the ordinary courses in biology, which will include the reproductive system. In this way a child will learn everything necessary for the purpose of instruction, without the personal element which naturally arises when such matters are talked of between mother and daughter. A mother's influence may well be exerted over a daughter as to modes of life and behaviour, but we think it often useful that the ground-work in sexual knowledge should be given by the school teacher. Not that we wish to imply that Dr. Latimer objects to school education in the matter, only she puts it second while we should put it first in many cases. There can be no general rule. To pass to the rest of the book, the chapters on hygiene, daily life, and dress are for the most part admirable, and Dr. Latimer's remarks on corsets, their use and abuse, are very sound. As to dress, the following sentence (p. 284) wants revision: "The chemise, being made of cotton or linen, soon becomes damp ..... and as both linen and cotton are bad conductors of heat, the warmth of the body easily escapes." If a warm body is surrounded by a *bad* conductor of heat it is kept hot. But as a whole the book is very good.

JOURNALS AND MAGAZINES.

The Dublin Journal of Medical Science.—In the March issue Dr. George S. Walton writes on the treatment of syphilis by intramuscular injections of mercury; he prefers

grey oil for ordinary use, but notes that calomel may be of value in urgent cases, though the pain caused thereby is considerable. Dr. Malcolm K. Acheson discusses duodenal ulcer, and gives some personal experiences of the malady, noting the value of Lenhartz's treatment; and Dr. W. H. Thompson contributes some remarks on the subject of medical education, taking apparently a more favourable view of the existing curriculum than most writers adopt.

The Birmingham Medical Review.—An interesting paper on myopia by Mr. Henry Eales appears in the February number of this review. He points out the many dangers incidental to this condition and enumerates the measures to be taken to prevent its onset in the young. Mr. W. Arthur Loxton deals with rosacea, in which affection he holds that there is always present a predisposing condition of seborrhœa, dietetic errors and dyspepsia acting only as contributory causes.

Reports and Analytical Records
FROM
THE LANCET LABORATORY.

GALENICAL PREPARATIONS OF CALCIUM SALTS.
(GALE AND CO., 15, BOUVERIE-STREET, FLEET-STREET, LONDON, E.C.)

THE preparations submitted included elixir calcii chloridi, elixir calcii lactatis, elixir calcii iodidi, unguentum calcii iodatis, and pills containing the iodide and lactate of calcium. The interesting feature of the elixirs is that they are pharmaceutically elegant preparations, bright, palatable, stable. We submitted to analysis the iodide, chloride, and lactate elixirs and found present the amounts of calcium salts stated. The value of these salts is recognised in their power to increase the coagulability of the blood. The lactate has been used in troublesome cases of chilblains. The iodate of calcium ointment has been used, it is stated, with marked success in cases of troublesome persistent eczema, and the pill is frequently exhibited as a specific in various forms of this malady. The fatty basis is very satisfactory, sweet, bland, and clean, and not liable to become rancid.

KOLYNOS DENTAL CREAM.
(KOLYNOS INC., 4, FARRINGDON-AVENUE, LONDON, E.C.)

We have submitted this preparation to careful analysis, and in the result find that we agree with the statement handed to us in regard to its composition. It may be said briefly that the antiseptic agents present are benzoic acid, eucalyptus oil, peppermint oil, and thymol, and the vehicles respectively are soap, precipitated chalk, alcohol, and glycerine. Apart from the effective antiseptic agents present kolynos exhibits distinct skill in the way in which its ingredients are compounded. It is what pharmacists would call an elegant preparation. The mechanical action of a substance intended for application to the teeth is of importance. In the case of kolynos its mechanical action is pleasing and effective, whilst not damaging the enamel. The soap, chalk, glycerine, &c., have been so well compounded that while they cleanse the teeth they do not injure them, and preserve a clean, white, pearly surface. According to a report by Dr. E. Walter, of the Hygienic Institute of the University of Greifswald, the accuracy of which is attested by Professor Dr. Loeffler, kolynos is capable of destroying in a short time diphtheria bacilli, streptococci, and pneumococci, not only *in vitro*, but in the human mouth. By the regular use of kolynos, therefore, the maintenance of mouth asepsis is assured. A mouth-wash prepared on the same lines is an equally satisfactory preparation.

INDIA PALE ALE.
(WORTHINGTON AND CO., LIMITED, BURTON-ON-TRENT, AND MOORFIELDS CHAMBERS, 95 AND 97, FINSBURY-PAVEMENT, LONDON, E.C.)

The care taken to mature this ale and to bring it into fine wholesome condition is analogous to that exercised in the case of light wines. Before it reaches the public it is kept and watched for a definite period at that constant temperature which experience has taught conditions the beer. On examination the beer gave the following results: alcohol by weight, 5·87 per cent.; malt extractives, 3·76 per cent.; malt sugar, 1 per cent.; dextrin, 0·77 per cent.; protein, 0·427 per cent.; mineral matter, 0·30 per cent., containing 0·032 per cent. phosphoric acid; volatile acidity reckoned as acetic acid, 0·012 per cent.; and fixed acid reckoned as lactic acid, 0·207 per cent. Microscopical examination of the deposit showed it to be clean and to contain a few pure yeast cells. The soundness of the beer is evidenced by the small amount of volatile acidity represented in the acetic acid present. The beer is free from preservatives other than hops, no foreign bittering agents were detected, it has a pleasing delicate bitter taste, and is satisfactory to the palate. Beer when it is in the sound condition of this specimen is wholesome.

New Inventions.

A NEW ANASTOMOSIS DEVICE.

THE problem of speedy and safe union of the severed intestinal canal is sufficiently important to excuse my attempt to describe a new device for effecting the same. It may be taken that the most vital and primary considerations are: (1) that any device used to effect the union of one portion of the alimentary canal to any other should be capable of very rapid and very easy application; (2) that this should be effected with as little handling of the parts as possible; (3) that when applied the device should be efficient—i.e., continuously *water- and gas-tight;* (4) should not be capable of having its lumen closed by tumefaction of the mucosa; (5) should be as light as possible; (6) should be easily transmitted by the peristaltic action of the intestine when its work has been accomplished; and (7) should not give rise at any time to obstruction. All of the above points of efficiency are claimed for the instrument to be described. It consists of two lateral halves (metal), which, when joined together, as in Fig. 1, have the appearance of an elongated ovoid or torpedo. The closed instrument provides an elongated lumen, surrounded by an oval serrated clamping edge, having outside this three pins on either side, and, lastly, and most externally, a flattened flange for keeping the opposed peritoneal surfaces in constant apposition. The essential features of the instrument are: (*a*) its shape, which ensures its constant passage (when once free in the intestine) along the intestine. It cannot get athwart the intestine and remain so, because it has a constant tendency to lie parallel to the axis of the bowel. If, however, it were to become temporarily caught across the gut its large aperture will prevent obstructive symptoms. If it lie in the long axis of the gut it must, by reason of its shape, be propelled onwards in the direction of least resistance, and so find its way out. This is an important point in view of the fact that the ordinary Murphy's button has given rise to serious obstructive symptoms (especially in the small intestine) by being caught and held immovably fixed by intestinal tonic contraction (cf. gall-stone intestinal obstruction). (*b*) Its functions are that it renders any preliminary stitching of the gut unnecessary. It renders lateral anastomosis easier than end-to-end anastomosis with Murphy's button. It is designed to prevent all chance of gaping at the site of application until after the peritoneal surfaces are safely glued together, so that no subsequent contraction of the gut will cause leakage. The three pins (see Fig. 2) on each side also act as additional safeguards for fixation, as well as sureties for exactness of apposition at the time of application. At each end of the

instrument is a peg and tube-guide device to effect certain accurate and permanent locking of the instrument. The teeth on the locking pegs (see Fig. 3) after passing up the tubes in Fig. 2 become engaged by a pawl which springs into and engages the teeth on the peg (or ratchet) and will not become undone until freed by the opening key (see Fig. 4) after the instrument is evacuated. It can be made as light as desired and entirely of non-corrosive metal. The instrument tends to cause the formation of a larger aperture of intercommunication than it itself shows, as all the gut wall included within the serrated teeth and the outermost edge of the flanges usually becomes absorbed and destroyed, thus leading to a free communication. It does not necessitate "puckering" of the line of union, with consequent post-operative obstruction. This instrument was devised purely for the lateral anastomosis of the large and small intestine, and the short circuiting of the pelvic colon in senile intestinal atony and the condition called falsely

FIG. 1.

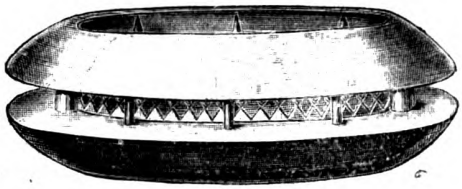

FIG. 2.

FIG. 3.

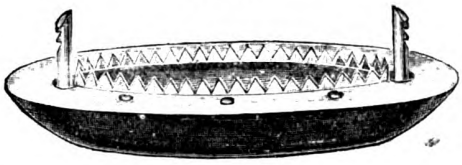

FIG. 4.

congenital or idiopathic dilatation of the colon. It is applied as follows. Where the gut has been resected and a piece removed, as in gangrenous strangulated hernia, &c., half the instrument is inserted into either end of the bowel and the ends sewn up by purse-string and mattress sutures, and all made secure. Each half now lies within either section of bowel. Each half is now taken up by grasping the bowel, and the pegs on one half and the guide-tubes and pins on the other half are gently pressed through the bowel wall by dissecting forceps, the gut wall on either side is incised opposite the lumen of the clamp, the pegs are fitted into the guide-tubes and the halves of the instrument pressed home until the first locking is effected, and, if then the joint is not quite secure, until the second locking is effected, when the bowel wall will be firmly gripped and fixed, and the line of union hermetically sealed. A few Lembert sutures outside are now purely a matter of individual preference. In cases of cancer of the cæcum, where large and small intestine need to be approximated, this device proves useful; also in cases of cancer of the colon. As a means of uniting intraperitoneally the descending colon to the anterior (peritoneal) surface of the rectum low down in the pouch of Douglas it presents several advantages. The instrument described and illustrated has been made to my requirements by Mr. H. L. Trudgett of 26, Darnley-road, Hackney, London, to whom my thanks are due for excellent workmanship.

F. W. FORBES-ROSS, M.D. Edin., F.R.C.S. Eng.,
Late Civil Surgeon, His Majesty's Guards' Hospital, London.

A CURETTE FOR THE EUSTACHIAN TUBE.

EVERY otologist has experienced the reinfection of his radical mastoid operations through the Eustachian tube, and various suggestions have been made as to the best means of closing that pathway. I have found the curetting of the tympanic ostium of the tube to fail very frequently, and attempts at closure by remnants of the tympanic membrane (as suggested by several American aural surgeons) are equally unsatisfactory. I have, therefore, recently devised a

fine curette of steel, welded on a copper stem, which can be passed with ease into the tympanic ostium and outer half-inch of the Eustachian tube, for the purpose of thoroughly curetting this outer portion.

I have now used this curette, which was made for me by Messrs. Krohne and Sesemann, in several cases with excellent results, the curettement appearing completely to close the tube and to cut it off from the nasopharynx.

MACLEOD YEARSLEY, F.R.C.S. Eng.,
Senior Surgeon to the Royal Ear Hospital, &c.

UNITED SERVICES MEDICAL SOCIETY.—The next meeting of the above-named society will be held at the Royal Army Medical College, Grosvenor-road, S.W., on April 13th, at 8.30 P.M., when a paper will be read by Lieutenant-Colonel H. E. Deane (retired), R.A.M.C., on Records of Pulse Rates after Exercises of Various Kinds in Trained and Untrained People, illustrated by sphygmograms.

FIRST INTERNATIONAL SPANISH CONGRESS OF TUBERCULOSIS.—This congress will take place at Barcelona from Oct. 16th to 22nd, 1910. Dr. D. Rafael Rodríguez Méndez, professor of medicine, is the President of the committee of organisation, and has just issued a little handbook on the congress. The congress is to be held under the patronage of the King and Queen and the Queen Dowager, and is officially recognised by the Spanish Government, which has named His Excellency Señor Don Angel de Larra y Cerezo, of the Royal Academy of Medicine of Madrid, as its delegate and representative, while delegates from several South American states will participate. The congress will consider tuberculosis from the scientific, preventive, and humanitarian points of view. It will be divided into the following sections—Bacteriology, Statistics and Demography, Medicine, Gynæcology, Pediatrics, Oto-Rhino-Laryngology, Military Sanitation, Veterinary, Hygiene and Social Action, Sanitary Engineering, Architecture, Serum-therapy, Therapeutics, Pharmacology and Applied Chemistry, Legal and Psychiatric Medicine. There will also be a ladies' committee, over which Donna Leonor Canalejas de Farga, professor of the Normal School of Mistresses of Barcelona, will preside. The following prizes are offered to members of the Congress by the Spanish Government: one of 2500 pesetas and two of 1000 pesetas each for three theses; the Diputacion Provincial de Barcelona is offering one prize of 1000 pesetas for a thesis, and other corporations and societies are offering objects of art as prizes. The theses must be written in Spanish, and will be received by the secretary-general up to August 31st next. They are confined to members of the Congress. There will be an exhibition attached to the Congress, the President of the organising committee of which is Dr. D. Antonio Rodríguez-Morini, whose offices are at Rambla de Cataluña, 43, 2°, Barcelona. There will also be an assembly at the Spanish Medical Press, of which the President is Dr. D. Joaquín Durán Trinchería of the *Revista de Ciencias Médicas*. Travellers are recommended to apply with respect to lodging in hotels and so forth to the Sociedad de Atracción de Forasteros" (Society to Attract Visitors), whose address is Rambla del Centro, 30, bajo, Barcelona. Various excursions will be made with the coöperation of this society. Correspondence should be addressed, according to the nature of the business, either to the President, whose address is Paseo de Gracia, 42, ent.°, Barcelona; or to the Secretary-General (Dr. D. Andrés Martínez Vargas), Gran-Vía (Cortes Catalanas), 604, 1°., Barcelona; or to the Treasurer (Dr. D. Enrique Robledo Negrini), Consejo de Ciento, 323, 1°.

THE LANCET.

LONDON: SATURDAY, APRIL 9, 1910.

The Recommendations of the Departmental Committee on Coroners.

THE Departmental Committee appointed by Mr. HERBERT GLADSTONE (now Lord GLADSTONE) in 1908 to inquire into the law relating to coroners and coroners' inquests and into the practice in coroners' courts has issued in a second report its recommendations upon these subjects, of which a summary was published in THE LANCET last week.[1] As our readers will have seen, some very difficult and complex matters have been closely considered, while one such—namely, the matter of deaths under anæsthetics—will be made the subject of a further report. The declaration of the views of the committee upon this question, which was submitted for consideration as an afterthought, and with regard to which evidence was heard simultaneously with evidence relating to the law and procedure connected with inquests, is awaited with interest. The report, as a whole, is one which should be regarded with satisfaction by the medical profession, for it recognises the importance of enabling the coroner to obtain the best medical evidence reasonable of attainment with a view of establishing the cause of death; while in order that the coroner's position and authority may be strengthened it recommends that the office should be confined to members of the medical and legal professions. Those who read the opinions thus expressed side by side with the Act of Parliament now governing their subject matter, the Coroners Act, 1887, are tempted to wonder how it came about that very little more than 20 years ago all provision for scientific evidence of the cause of death in any but the simplest cases was omitted. A scale of fees for medical witnesses was incorporated in the body of that Act which the committee recognises to be causing great and justifiable dissatisfaction in the medical profession, and which in one instance (the inclusion of the chemical analysis of the contents of the stomach and intestines with the post-mortem examination) it characterises as ridiculous. To take another instance of an anachronism not connected with the progress of science, we need only refer to the retention in the Act of 1887 of the condition that a county coroner must have "land in fee sufficient in the same county whereof he may answer to all manner of people." We need not discuss the usefulness of such a qualification in the reign of EDWARD III. In more recent years it is said to have been satisfied, if any notice has been taken of it, by the possession of a freehold grave in a cemetery, and the committee recommends that in future the requirement should be abolished and that fitness acquired by training in medicine or law, or both, should be substituted. Perhaps the year 1887 must now be regarded as having occurred during a period of transition, and the date at which the future Coroners Act finds its place in the statute book will come to be looked back upon by posterity as the one at which the medical profession found itself definitely established in a position but recently won. An important recommendation of the committee bearing upon the possibilities of future progress and development, not only in scientific discovery and medical science, is that which advises the giving of powers to make rules for the practice and procedure of the coroner's court to a central authority. No such power now exists, and the difficulty of keeping pace with the times by means of fresh Acts of Parliament is obvious.

In the summary of the report which we have published will be found many suggestions and recommendations affecting the general usefulness of the coroner's office, but not of special interest to the medical profession. Among those, however, which are of medical as well as of public interest, by far the most important subject dealt with will be found in paragraph 15. Hitherto the coroner has had to decide whether he should hold an inquest or not without having the power to order a post-mortem examination, the one method by which he could frame his decision with the least possible risk of error. The committee in advising that he should have this power keeps in view the probability that inquests will thereby be diminished, and this recommendation lends weight undoubtedly to the one contained in paragraph 5, to the effect that a coroner should be paid by salary in all cases and not by fees dependent upon the holding of inquests. It also adds support to the contention, upheld constantly and strenuously in THE LANCET, that it is desirable in the interests of the public that all coroners should have been medical practitioners, for a preliminary post-mortem examination may convey little to the man without medical training. In advocating the appointment of medical coroners, however, we have never lost sight of the fact that the coroner's court is a court of law. Legal training and experience are both of very great importance in the exercise of the coroner's duties, and no doubt a combination of medical and legal training presents the most desirable preparation for the post. The need for the coroner to be able to grasp, or shall we say conjecture, the medical aspects of a case without a post-mortem examination to guide him has been combined in the past with the desirability that he should be able to weigh and explain medical evidence to a jury at an inquest. In future, if the coroner should be allowed to order a post-mortem examination as a precedent to an inquest he will have to call upon medical knowledge in no less degree in order to understand the fuller medical information at his command and to apply it to facts which will be in his possession, but which will not have been before the pathologist. The latter will inform the coroner of the physical conditions found in the dead body the potential subject of an inquest. The coroner will have to say whether those physical conditions, which may not by themselves indicate any need for public inquiry, may render an inquest desirable in combination with circumstances as

[1] THE LANCET, April 2nd, p. 942.

to which he has learnt that evidence may be forthcoming. In other words, he will sometimes have to make up his mind as to whether facts, in themselves not inconsistent with natural death or perhaps pointing strongly to it, may in truth be attributed in some measure to criminal acts or culpable neglect, or, at any rate, whether features may exist in the case requiring elucidation. In doing so he will have the advantage of his experience as a coroner and of the information supplied to him as such (part of which may emanate from medical men), but these in some instances might be rendered useless if there were not medical knowledge on his part to supply the link between the matters suggested by his official inquiries and those established by the post-mortem examination. We commend these considerations to the attention of those who at some date, which we hope is not far distant, will undertake the promotion of legislation upon the lines of the committee's report.

The paragraphs in the report dealing with the calling and remuneration of medical witnesses are highly important. Paragraph 29 proposes to do away with a power possessed by the jury to select medical witnesses, which power certainly seems inconsistent with the enjoyment by the coroner of that exclusive authority in his court which a judge should possess. Under Section 21 of the existing Act a majority of the jury may insist upon the calling of additional medical evidence, and may name the witness whom the coroner is then obliged to summon. The curious point with regard to this is that it has been the privilege of the jury only, and that the coroner who is dissatisfied with medical evidence has had no authority to obtain and pay for better, though no doubt he may have been able to do so under the section with the jury's coöperation. The other paragraphs with regard to medical evidence will be found to recommend better provision than now exists for the remuneration of those supplying it, and the granting of power to the coroner to obtain in cases where such may be required the assistance of those highly qualified witnesses who in the simpler everyday cases of the coroner's routine work would be out of place. The committee points to Scotland as furnishing an example of what it holds to be more desirable than the present English system, and makes the important and commendable suggestion that "to give coroners a somewhat wider discretion as to costs—a discretion possessed by all other courts—would go far to remove the friction which sometimes arises between them and the medical profession, and would, on the whole, be conducive to the efficiency of inquests and the public interest." These words will be found in our summary already referred to, and are quoted from a paragraph in which the committee expresses its views upon the question which has frequently been discussed in these columns with reference to the practice of a particular coroner in London in employing a pathologist from outside his district for the making of all post-mortem examinations. With regard to this we note that the committee points out that "clinical evidence may be essential to supplement the evidence as to the post mortem," and adds: "The coroner is in a difficulty because, if the Act is strictly interpreted, he cannot pay both the medical witness who gives clinical evidence and the medical witness who makes and gives evidence as to the post-mortem examination. Every coroner should be empowered to call such medical witnesses as may be necessary for the proper determination of the case." With this the medical profession is likely to be in agreement. The difficulty which has arisen in Westminster during recent years has been due to the coroner employing on his own initiative, and in a manner not contemplated by the Act of 1887, a pathologist whose evidence was not given in corroboration of, but in substitution for, that of any other medical evidence as to the death which might be available. We contributed to the calling of attention to this course, and if as a result a new Coroners Act renders the employment in special cases of an independent pathologist legal, without ousting the evidence of any medical witness who, being summoned immediately before or after death, or being otherwise acquainted with the condition of the deceased, has valuable evidence to give, the investigation of the coroner's jury will be made far more satisfactory than heretofore. We note that, with reference to the medical practitioner to be selected for the making of the post-mortem examination, Mr. A. J. PEPPER, whose unrivalled experience gives weight to his words, said in his evidence before the committee: "In the vast majority of cases the general practitioner is quite capable of conducting the post-mortem examination and giving the necessary evidence." The same witness also said: "I think that any medical man, whether he has attended the case previously or has simply known the person, or has been called in at the time of death or immediately afterwards, should always be called in," and he added that such evidence was undoubtedly essential, whereas to obtain information from a medical practitioner in such circumstances and then to refrain from summoning him as a witness was "perfectly monstrous." Agreeing as we do with these opinions, we should suggest that the enlarged discretion to be allowed under any new statute to coroners in the summoning of medical witnesses might usefully be governed by regulations so as to ensure the calling of all essential witnesses. Such rules framed by a central authority would guide without circumscribing the exercise of the coroner's judgment, and would prevent the reduction of medical evidence to a possibly dangerous minimum in order to save expense at the dictation of an economically minded local authority.

We note with satisfaction that the departmental committee is emphatic in its declaration that the depriving of the officers of medical institutions of all fees in respect of evidence given at inquests is inequitable and should cease. Dr. F. J. WALDO in his evidence ascribed this provision to the prejudice excited by the case of the infamous body-snatchers and murderers BURKE and HARE. In any case, it is another instance of an anachronism which found its way into the Act of 1887, and which has survived to the prejudice of the public and to the injury and irritation of members of the medical profession for many years. That it so survives, in common with other relics of machinery antiquated and obsolete in connexion with the exercise of an important judicial office, is a further reason why the law and procedure affecting inquests should be renewed and amended with as little delay as possible.

Recent Cancer Research.

WE publish to-day two papers based upon the study of mouse cancer, one by Dr. ARCHIBALD LEITCH and the other by Mr. CHARLES WALKER, which should be read in connexion with the two papers presented to the Royal Society from the laboratories of the Imperial Cancer Research Fund, which we published a fortnight ago. All four papers treat of highly specialised investigations similar to many which have been recently reported in our columns and in those of other journals, and we may expect, having regard to the fact that 40,000 or 50,000 experiments are made yearly on cancer in mice and rats in this country alone, that such communications will grow more numerous. There may be some risk that those not working in the special field will have difficulty in appreciating how much further the results, as they are reported, bring us to the solution of fundamental problems in cancer pathology; it will be useful, therefore, to summarise the story as it at present stands, as far as this can be done when the subject matter is so complex.

The successful transference of cancer from one individual to another is merely the experimental production of a secondary growth, with the difference that it is established in an animal other than that in which the primary growth arose. With suitable methods all the clinical and pathological features of the local progress and of the dissemination of a primary growth can be reproduced in mice or rats by introducing a pin's point of cancer tissue—theoretically by a single cell. The lessons which some years of continuous study at many centres and in many laboratories have taught are mainly five. First, it has been demonstrated that the cancer tissue grows from its own resources only, and therefore the increase in the area of a growth is not necessarily, nor even probably, due to progressive transformation of healthy tissue into cancer. Since all the consequences which make up the disease follow from the continued growth of a tiny piece of tissue, the practice based upon recognition of the circumscribed origin of cancer, and therefore on the possibility of its complete surgical removal by cutting into the surrounding healthy tissue, is experimentally justified. Recognition of the force of this demonstration has led surgeons to modify their opinions and their practice. The idea of a pre-cancerous stage has given place in most minds to that of a cancerous growth too small to be clinically recognisable with certainty, while the practice of immediate removal of doubtful thickenings and ulcers has taken the place of expectant postponements, with great improvement in results. Second, the cancer cell has been demonstrated to be practically innocuous to individuals other than those in which it has arisen. While as many as 900 fragments of cancer may be inoculated into a corresponding number of normal mice no fragment may be found to grow, whereas if removed and put back again into the mouse where they arose the "takes" number from 95 to 100 per cent. of the inoculations. For these and many other reasons experimental study has led to the conclusion that cancer is not infectious, that the presence of some 50,000 persons suffering from cancer in the community constitutes no menace either to the public or to the immediate relatives of the sufferers. Third, the cancer cell is part and parcel of the individual attacked. It would seem that we are merely brought back again to a conclusion VIRCHOW held 60 years ago, and JOHANNES MÜLLER, PERCIVAL POTT, and others before him. But THIERSCH, and more particularly WALDEYER, showed VIRCHOW'S idea that the epithelial cells of a cancer crystallised out of the humoral matrix to be wrong. WALDEYER held that these cells grew in continuity with the covering epithelium, and that the secondary growths were the genealogical descendants of transplanted epithelial cells. The modern results are really a confirmation and an extension of those arrived at by WALDEYER in 1867, since when the bacteriological study of disease has been entered upon, and for more than 30 years cancer has been attacked from bacteriological and other parasitological standpoints. The advocates of an exogenous or parasitic origin and those of the autochthonous origin of cancer stood sharply opposed up to the establishment of investigations upon a broad experimental basis. Neither school could effectually refute the arguments of the other, and each was unable to demonstrate the impossibility of an alternative to its own views. Finality, as far as it is ever possible, has been attained by the experimental method, and to-day we believe that few who have done some practical work in the pathology of cancer believe that cancer has analogies with any known form of infective disease. Fourth, the cancer cell has ceased to be intangible and mysteriously entrenched behind unassailable ramparts. It has been brought out into the open and made to disclose its behaviour under all sorts of varying conditions favourable and unfavourable to the exhibition of its powers. True, it is only the properties of the ready-made cancer cell that are being studied, but yet with such exactness that indirect conclusions as to its nature may be drawn with greater probability than ever before. A yearning of 35 years ago—"What a subject for DARWIN would be the cells of a cancer if only they were tangible; how the immortal pigeon would be completely eclipsed, while the hungry pathologist would be filled with food, if only we could observe the variation of tumours under judicious observation!"[1]—has been converted into a reality. The advocates of the autochthonous origin of cancer have long been divided among themselves. While some denied that a cancer cell was different from a normal cell, asserting that it grew because all cells grow if they get the chance, others assumed that only a fundamental biological difference could explain the facts. Here again experiment has enabled a choice to be made; biological differences between normal cells and cancer cells have been shown to exist. In the study of the relative constancy and the variability of tumour cells under artificial propagation light is being thrown upon the nature of the relationship obtaining between the normal cell and its abnormal derivative, and upon the relationship between prolonged chronic irritation and the onset of cancer. Fifth, the cultivation and inoculation of the cancer cell have made it possible to attempt to modify or to rob it of its dangerous properties.

With this special task are concerned the papers we publish to-day by Dr. LEITCH and Mr. WALKER, as were also those

[1] James F. Goodhart, M.D.: On Cancer as Illustrated in Ichthyosis of the Tongue and Allied Diseases resulting from Prolonged Local Irritation, Guy's Hospital Reports, 3rd Ser., 1875, xx.

in our issue of March 19th by Dr. BASHFORD, Dr. HAALAND, and Dr. RUSSELL. Immunity to the inoculation of cancer from one individual to another is now a well-established fact. It can be conferred by an antecedent vaccination either of tumour tissue or of normal tissue of the same species, but as yet it has not been found possible to separate the power of immunising from the vitality and the power of growth. Only living cells immunise. It has been within the common knowledge of experimental investigators that exposure to light, heat, cold, X rays, radium, and physical disintegration or chemical modification rob the cancer cell of its sinister powers to produce tumours.

All of the claimants to the successful induction of immunity from JENSEN and BORREL in 1903 onwards have employed living tissues, although not all have emphasised the point. Thus, writing in April, 1906, EHRLICH stated, "In contrast to my predecessors who have employed carcinoma tissue killed by chemical means, I have used another method of immunising which corresponds to vaccination with an attenuated virus." Certain immunising powers of cancer cells and of normal cells appear to be inseparable from their vitality. This conclusion is arrived at for homologous immunisation—i.e., when tumour tissue or normal tissue is inoculated into animals of the same species—by Dr. LEITCH and by the workers of the Imperial Cancer Research Fund. Mr. WALKER emphasises its importance for heterologous immunisation—i.e., when tumour or testis of the mouse is inoculated into rats with the object of obtaining an anti-serum. The importance of using the living intact cell for heterologous immunisation has not been so prominently emphasised before, and this paper goes farther than the other three in appearing to arouse again hopes that an anti-cancerous serum may yet be found. One of the still unsolved contradictions between the results of different investigators is the unequal success attending efforts to obtain a serum acting on the cancer cells, killing them *in vitro* and curing living mice of tumours. There is no reason to doubt the accuracy of the observations recorded in 1903 by JENSEN, in 1905 by CLOWES, and in 1908 by WALKER, but there appear to be many controllable and uncontrollable factors to be reckoned with before one can be certain that cures have actually been effected. Mr. WALKER cautiously pointed out in his first communication, "Very great and obvious difficulties will have to be overcome before this line of experiment can be carried to the point of treating the human subject," adding that tremendous risks and failures must attend any premature application. Substantial progress, however, has apparently been achieved in defining and discussing the proper standpoint from which to advance.

THE WATER-SUPPLY OF ST. IVES (CORNWALL).—The opening of the new waterworks at St. Ives took place on March 28th in the presence of a large gathering. The new works are situated at Halsetown; the reservoir is eight acres in extent, and has a capacity of 22,000,000 gallons of water. The cost of the undertaking has been £14,640.

The Evolution of the Nursing Home.

THE progress of surgery, especially that associated with the introduction of antiseptic surgery and its more modern representative or development asepsis, has led to enormous changes in the arrangements made in hospitals for the carrying out of those principles that are considered of vital importance by the surgeon of the present day. Great though the changes of recent years have been in the medical wards of a hospital, they have been vastly greater in those portions of the hospital which are devoted to the care of surgical patients and the performance of surgical operations. Rooms and theatres with which the surgeon was thoroughly contented three or four decades ago would now be looked upon as hopelessly out of date and in many ways unfitted to be the scene of any surgical treatment whatever. A lavish expenditure of money has brought most of the hospitals, especially in the larger towns, to a degree of perfection which was unthought of not many years ago. These advances in the arrangements made for the care of surgical cases are, however, in great part confined to hospitals, and they who profit by them are mainly the sick and injured poor. Thus it has come to pass that the greatest facilities for the treatment of surgical cases are utilised, not for those who can best afford to pay for them, but mainly for those who cannot pay at all.

The good that the nation as a whole gets from this perfected technique is large, and the richer sections benefit in a secondary manner from the elaborate care taken of the hospital surgical patients. But at the same time for the wealthy, and also for those who are moderately provided with this world's goods, the arrangements made are far less satisfactory when surgical skill is required. Not many years have passed since all who did not enter the walls of a hospital for surgical treatment had to be content either to remain within their own homes or to receive surgical attention at an ordinary lodging-house; nor was this any hardship when the mortality in the surgical wards of the hospitals was maintained at a high level from sepsis. But with the adoption of the Listerian principles there soon came a time when results could be obtained in hospitals that could not be expected in improperly equipped domestic dwellings. Some years, however, elapsed before any special houses were provided for the reception of surgical cases, although the idea that such houses might be useful was quite an old one. A hundred years ago there were, it seems, some houses where surgeons were in the habit of seeing and treating patients, but it was not until the modern phase of nursing arose in sequence to the discovery of antiseptic surgery that anything like a modern nursing home came into existence. And even after the name of "nursing home" became familiar to the public little real endeavour was made to provide genuine hospital amenities. The building was still an ordinary house, chosen for its nearness to the districts where operating surgeons lived, and from its very construction it could not be looked upon as specially suitable for the treatment of many sorts of cases. Gradually the conditions improved, and the real nursing

home has been evolved. Stress has been laid on the condition of the drainage. The decoration and the furnishing of the rooms have been arranged so as to render them more suitable for patients, and in many cases one or more rooms specially arranged for operations have been added. Yet, with the best intentions on the part of the proprietors of these establishments, the results cannot be regarded by the modern surgeon as wholly satisfactory, and the conditions in many of our nursing homes lag far behind those that exist in most modern hospitals. In the provision of private accommodation suited for the treatment of surgical cases we are distinctly inferior to many other countries. In France and Germany, in Canada and the United States, in Australia and New Zealand, it is customary for surgeons who have an extensive practice to maintain private clinics, as they are called, where they send the patients under their care. These are, in fact, small hospitals where everything that modern science can devise has been done to render the buildings suited for the purpose for which they are employed. The surgeon to whom they belong has full control of the building, the equipment, and the drainage of the hospital. Even the nursing, though under a matron, is carried out exactly according to his wishes, and, in fact, he makes sure that every condition is arranged so as to be best suited for the health and the recovery of the patient under his care. The operating theatre is as perfect as surgical science can devise, and the sterilisation of dressings and instruments is carried out as he would have it. When all this is done the conditions are even more favourable than those in ordinary public hospitals, where, however excellent the arrangements may be, they cannot always be adapted exactly to the requirement of individual surgeons.

In this country the private clinic is now established to some extent, but there are certainly many professional men who do not approve of the innovation. Indeed, some consider that all nursing homes take patients away from the general practitioner to an unfair extent, receiving within their walls cases which could easily be dealt with outside. Undoubtedly this may occur, but against this disadvantage, which is growing less real as time goes on, must be put the obvious advantage to the public of having access to a really well-managed nursing home. There are not too many of them, and it is easy to believe that where money is no consideration the patient's private house could be transformed into a better hospital than many nursing homes can claim to be. For no operating surgeon will dispute the statement that the conditions obtaining in many nursing homes, especially those devoted to surgical cases, are capable of material improvement. This has been widely felt, and there has been a movement for their compulsory registration and periodic inspection. This would be a drastic course to insist upon, but it could be justified. Such inspection would tend to remedy various sanitary defects that certainly exist in some places. But inspection would certainly do nothing to remedy those defects of construction, of management, and of detail which so decrease the chances of successful surgical treatment. It is the surgeon alone who is capable of dealing with these important points. On him rests the responsibility of the outcome of the treatment, and to him must be given the control of all the conditions which make or mar the success of his operation. We have not the faintest wish to depreciate the care and attention bestowed by the majority of proprietors of nursing homes on the cases put in their charge. To the best of their ability they carry out what they consider to be necessary, but they do not, and cannot always, comprehend the importance of many things which are familiar to the surgeon. As matters stand it is only prudent that a practitioner should have personal knowledge of every nursing home to which he may sanction the removal of his patients, and we recommend all medical men, whether they be the family advisers or the operating surgeons, to insist on the right to make the fullest inquiry into the construction and arrangements of any institution which they may design to use.

Annotations.

"Ne quid nimis."

EGYPTIAN OPHTHALMIA.

TRACHOMA, known under the name of Egyptian ophthalmia or by another synonym, military ophthalmia, has for centuries been the cause of much blindness in Egypt. The census of 1907, which probably understates the real number of sufferers, because of the natural reticence to declare personal or family infirmities, shows that more than half a million Egyptians are blind in one or both eyes. Those blind in one eye amount to 3·2 per cent. of the population, while another 1·3 per cent. were returned as blind in both eyes. It is difficult to make comparisons with other countries, but it may be noted that blindness in Egypt is 55 times more frequent than amongst the coloured folk in Idaho, which is the State where blindness is most rife in the United States of America. Russia is one of the European countries where trachoma has wrought terrible havoc among the peasants, till in 1893 a benevolent society in St. Petersburg inaugurated a system of "flying columns" of ophthalmic surgeons and nurses to visit all parts of the country in order to try to relieve the vast mass of suffering from ophthalmia. The seven columns of the first year were increased to 36 by 1898, which treated 50,222 patients, of whom 3432 were found to be irreparably blind. In 1903, when Sir Ernest Cassel presented £40,000 for the relief of ophthalmia in Egypt, it was felt by the Public Health Department that the Russian experiment with certain modifications could be imitated with advantage. Two moveable ophthalmic hospitals were therefore placed under the control of Mr. A. F. MacCallan,[1] each consisting of a dozen large Indian tents furnished with the necessary equipment and a complete set of ophthalmic instruments. The staff consists of two Egyptian surgeons at each hospital, besides attendants and servants. Twelve in-patients are provided for, but the bulk of the work done is among patients who attend daily, including all cases of trichiasis. About 300 patients attend every day during summer and winter, and full clinical notes are kept of every patient treated. Each camping ground in or near a town is occupied for a period of about six months, when work is transferred to some other place. The change is made not because there is any diminution in the number of applicants for treatment, but because it is considered fairer to give to different provinces the advantage of ophthalmic treatment. The patients apparently

[1] The Relief of Eye Disease in Egypt, with some Consideration of the Incidence of Blindness and Trachoma, by A. F. MacCallan, M.B., F.R.C.S. A paper read at the Sixteenth International Medical Congress at Budapest in September, 1909.

belong to the poorest classes and are treated gratuitously. Seven years ago nothing was done for ophthalmic cases in Egypt excepting, to some extent, at the Government hospitals, and there were no ophthalmic surgeons of repute outside Cairo and Alexandria. To-day the travelling hospitals have aroused some interest in the country, £10,000 have been privately subscribed by the Egyptian public for building purposes, and to this sum the Government has added £15,000, besides paying more than £5000 a year for maintenance. In addition to the two travelling hospitals, three permanent eye hospitals are now built or are in course of construction. Trachoma seems to be almost universal among the middle and poorer classes, so that at Tanta, the chief provincial town of Lower Egypt, 96·4 per cent. of the pupils of the Government primary school were found to be suffering from it. Among 18,239 patients examined at the ophthalmic hospitals during the year 1908, no less than 6439 were cases of trichiasis or entropion, in every case the result of trachoma. It is hardly wonderful that Mr. MacCallan should doubt that conditions in past times can ever have been much worse than they are to-day. Yet, at the beginning of the nineteenth century the French military surgeons, such as Bruant and Savaresi, wrote of the prevalent ophthalmia in the French army in Egypt, and said that it attacked equally the rich and the poor, the townsfolk and the peasants, while one of them stated that the greater part of the dogs were blind. Such reports as these caused Lord Wolseley, in 1882, to include in his equipment veils and smoked glasses for the officers and men of the British army in Egypt. Fortunately, there was, and has been, very little ophthalmia in the army of occupation. Dr. F. Pruner, who wrote in 1847 on Egyptian diseases, stated that two-thirds of the foreigners were attacked by Egyptian ophthalmia, and he mentioned 20,000 cases treated in two hospitals which apparently comprised 3000 beds. Other European writers of that date and even later tell us that they were in the habit of paying daily visits in the summer to inquire after the health of their colleagues, some of whom were sure to be ill of the two prevalent diseases—ophthalmia and dysentery. If these accounts are trustworthy we can see that there is a much greater freedom in the present day, at least among the Europeans.

THE TRUTH ABOUT VIVISECTION.

WE have received three pamphlets published by the Research Defence Society dealing with the above-mentioned matter. They are numbered VI., VII., and VIII. The first of the three, called "What the Doctor says," is a reprint of a speech delivered by Dr. R. J. Ryle at the inaugural public meeting of the Brighton and Sussex branch of the society; the second, called "The National Welfare," is by the Bishop of Winchester; and the third, "The Brown Dog," is a simple statement of fact about that notorious animal. The last-mentioned paper conveys its contents by its title, but the two others, that by the medical man and that by the ecclesiastic, should be read by every medical man and recommended to the attention of every layman. Both writers point out that by the results of experiments upon animals lives have been saved and suffering diminished among the human creation, and the Bishop in addition draws attention to the saving of life and suffering which has resulted among brutes by the discovery of the methods of infection of tubercle and of anthrax. It is difficult to convince the fanatical antivivisectionist, not so much because he cannot understand, or will not understand, but because his mental attitude is such that he cannot will to understand. For the ordinary man or woman whose minds are in doubt as to the righteousness or usefulness of vivisection, these papers should be of great value. The practice of vivisection should, of course, be carefully safeguarded. We do not deny that useless pain may have been inflicted in the past by certain investigators, although the perpetual contention that it was inflicted in wanton cruelty is a wicked perversion of truth. But vivisection nowadays, in this country at any rate, and we believe in most countries, is free from this reproach. As a means of research, and carefully safeguarded, it is almost the only method of scientific inquiry which has produced a succession of results of great humanitarian value. And as to the question of pain, we make bold to say that as regards this country there is more pain caused in one week's average shipment of decrepit horses to the continent (and that, it should be remembered, is purely a matter of money-making) than in one year's vivisection. We congratulate the Research Defence Society upon the temperate and accurate way in which these pamphlets are written, and especially on the fact that they have enlisted the advocacy of educated and thoughtful humanitarians among the members of other professions than the medical. In this connexion we note from a correspondence published recently in the daily press that the Church Antivivisection League has attacked the Bishop of North Queensland (Dr. Frodsham) for belonging to the Research Defence Society. The Bishop, in his reply, wonders whether the members of the league "have ever been brought face to face with the actualities of unknown disease," and proceeds to quote instances from the Tropics. He further states: "I cannot pretend to have done anything to relieve human suffering that may be compared with the work of medical men whose names are being held up by antivivisectionists to undeserved contumely. But I have very deliberately identified myself with such men because I believe them to be as adverse to cruelty as I know them to be filled with a burning zeal to alleviate human suffering; because I believe, with them, that experiments upon animals are justifiable, and can be conducted with due regard to animal life; and because I realise that the dissemination of facts upon the value of animal experiments is rendered necessary by the exaggerations and rhetorical license of antivivisectionists." Such a reply is worthy of a Father in God.

METALS AND MICRO-ORGANISMS.

THERE has been for some time a suspicion that metals wage effectual war against our common microbic foes, and a series of interesting experiments communicated to the Royal Society by Dr. A. C. Rankin, demonstrator in bacteriology at the McGill University, gives decided strength to the view. Sundry metals possess not merely a distinct inhibitory action upon the growth of moulds, bacteria, and other micro-organisms, but exert even a germicidal power. Water containing the typhoid bacillus and kept in a clean copper bowl becomes sterile. When air is passed through water containing abundant colon bacilli there is no inhibitory effect. Relatively large amounts of pure zinc with large surface area, placed in water contaminated with abundant colon bacilli and allowed to act for one hour, bring about a recognisable, but not extreme, destruction of the bacteria. Aluminium and copper, under similar circumstances, have no perceptible effect. The same experiment repeated, but with the oxygen driven out of the water by previous boiling, proved that none of these metals had any influence upon the subsequent growth of the bacteria. From this it would appear that such bactericidal activity of zinc as manifests itself is associated with the coincident presence of oxygen. A much more intense bactericidal action is produced when air is permitted to bubble for one hour through water holding the colon bacilli in suspension in the presence of aluminium, zinc, and copper.

With a sufficiency of the pure metal it is thus possible to render the water completely sterile with all three metals, and that when it contains abundant bacteria. In the case of zinc and aluminium the sterilisation process is accompanied by the production of easily recognisable amounts of peroxide of hydrogen and the formation of the hydrates of the two metals. In the case of copper there was, however, no evidence of the presence of hydrogen peroxide. Does the formation of hydrogen peroxide, which is, of course, decidedly germicidal, account for the action of the metals zinc and aluminum? and if so, how is it that copper acts equally well, but apparently without the formation of hydrogen peroxide? It may be that, in the case of copper, hydrogen peroxide is so rapidly dissociated after its formation that tests fail to find it. When, however, boiled distilled water is used in the place of tap-water zinc is found to have a decided germicidal action, and copper and aluminium act slightly. This result would appear to be the direct effect of the metal in solution, although the quantity dissolved must be extremely small. The subject is clearly of sufficient interest and importance to merit further investigation, and it would not be surprising if a key to the germicidal action of metals on bacteria in water is found in the ion. It is quite conceivable, at any rate, and especially with waters containing salts or free carbonic acid gas, that in contact with metal there is some dissociation. Some people assert that beer tastes better when imbibed out of a metal vessel, and if that is the case the liberation of ions might supply an explanation on the ground that they increase the palatability of the beverage. Again, the question naturally arises in considering this subject whether it is possible that our metallic cisterns afford water-consumers any protection against microbic invasion.

PNEUMOCOCCIC PYÆMIA.

IT has been recognised in recent years that acute pneumonia is only one of the lesions which may be produced by the pneumococcus, and that inflammation of other tissues, such as arthritis, peritonitis, meningitis, otitis, pharyngitis, and so on, may result. As the latter are rare and pneumonia by far the commonest lesion it has overshadowed the others. Since pneumococci frequently are present in the blood in pneumonia, and therefore the system generally is infected, it is curious that lesions other than pulmonary are so uncommon. At a meeting of the Société Médicale des Hôpitaux of Paris on Nov. 19th, 1909, M. Letulle and M. Leconte reported a case of pneumonia in which pneumococcic lesions of extraordinary multiplicity were produced. A chauffeur, aged 41 years, was admitted into hospital on June 21st, 1909, for pneumonia which had commenced on the previous day with a severe rigor and pain in the side. He had been long addicted to alcohol, and the colour of his face and tremor of the hands and tongue and excitement showed recent indulgence. There was right apical pneumonia, the temperature was 104° F., and the urine contained a little albumin. He became more excited and constantly endeavoured to get up, so that he had to be fastened to the bed. On the 25th he was calmer and the temperature had fallen to 101·5°, but although resolution was proceeding in the right lung signs of consolidation were found at the left base. On the 26th the temperature was 102·2°, and the patient complained of pain in his left ankle, which was swollen, slightly red, and tender. On the 27th the temperature was 104° and the joint was more swollen and painful; the swelling was periarticular as well as articular and extended up the leg, especially along the peronei muscles. Fluctuation was obtained behind the external malleolus. In consequence of these signs of suppuration an incision was made along the malleolus, causing the escape of much thick greenish pus. On the 28th the temperature fell to 102·2°. On the 29th there was found on the back, especially on the left side and at the lower part of the thorax, a large number of abscesses, of which some resembled the pustules of varicella, and others, a little larger, took the form of bullæ with seropurulent contents. From June 30th to July 12th a considerable number of these abscesses appeared in succession. The smaller ones rapidly dried up. The larger ones were opened and healed in two or three days. By the confluence of some of these a few large abscesses were formed; the largest, on the left shoulder, was 10 centimetres long. All the abscesses yielded the same kind of pus as that obtained from the ankle. After healing each abscess left a pigmented spot, of which 140 were counted, a figure lower than the total number of abscesses, because the smaller ones left no trace. During this period the general condition of the patient was, in spite of all this suppuration, fairly satisfactory. The temperature ranged from 100·4° to 101·2°. On July 9th the patient complained of slight difficulty in swallowing and the thyroid gland was found to be swollen and tender. An abscess developed in the left lobe and was opened on the 14th. After this convalescence proceeded without incident and the patient was discharged on August 16th with his left ankle-joint a little swollen and its movements impaired and painful. All the abscesses were proved to contain the pneumococcus in pure culture both by direct examination and by inoculation of mice. The recovery of the patient, in spite of double pneumonia, extensive suppuration, and alcoholic habits, is noteworthy. A case comparable to this has been recorded by an American writer, Shattuck, in which recovery took place after double pneumonia, jaundice, suppurative arthritis of the shoulder, double parotitis, and finally arthritis of the knee. Pneumococcic arthritis is a very rare complication of pneumonia. In reporting in our columns the first case observed in this country, Dr. E. J. Cave could find recorded by continental observers only 30 cases.[1] But cases of arthritis after pneumonia in the pre-bacteriological period are scattered through the medical periodicals. In 1902 Dr. Nathan Raw stated that pneumococcic arthritis was not so rare as was supposed, and published 7 cases which he had observed among 887 cases of pneumonia admitted to the Mill Road Infirmary, Liverpool.

MATHEMATICS AND MEDICINE.

THAT the Liverpool School of Tropical Medicine is in need of skilled statistical assistance may be gathered from a letter by Professor Ronald Ross, C.B., which appeared recently in the *Liverpool Courier*. In that letter he writes: "It may astonish some of your readers to learn that mathematics is required for tropical medicine, but I may say that this is most certainly the case. ..... Statistics have to be correctly examined, measurements exactly checked, and so on. In fact, pathology is now rapidly rising from a qualitative to a quantitative level. We could easily do with a trained mathematician to assist in the work of this school alone." The public spirit of Liverpool in matters of education is proverbial; it has abundantly been shown by the generosity with which the establishment and equipment of its University and its School of Tropical Medicine have been provided for, and we doubt not that eventually Professor Ross's appeal will meet with a satisfactory response. The question arises, however, whether the course now proposed is the best that can be devised in the circumstances. There is no doubt that medical science has already profited greatly by the application of statistical methods to the elucidation of the various problems of biology and

[1] THE LANCET, Jan. 12th, 1901, p. 82.

pathology. From Professor Ross's letter it would appear that he desires the appointment of a pure mathematician for his present purpose; but from what we know of similar arrangements elsewhere, we suggest that the assistance now asked for would be best secured by the appointment of a trained statistician, familiar with the medical points where figures are of the first elucidatory value, and familiar with the details of biological and pathological research. Such statistical problems as the local estimation of populations in intercensal years may safely be entrusted to persons without medical training, but no one who is not thoroughly versed in medical science generally could safely deal statistically with such matters as, for example, the distribution of disease or the mortality of occupations. It is in the department of State Medicine more particularly that the advantages of statistical treatment are demonstrable. The labours in this field of Farr, Rumsey, Parkes, and Hayward in this country, and of Bertillon and others abroad, have already borne good fruit, and at the present moment a thorough acquaintance with the principles and applications of vital statistics is regarded as an essential qualification for official appointment in our public health medical service. For the solution of nine-tenths of the ordinary problems all that is required is a sound knowledge of elementary algebra and geometry, such, for example, as that which is prescribed for graduation in the honour science schools of the University of London, and it is not unreasonable to demand the possession of that knowledge in all applicants for such a post as that which Professor Ross desires to establish in Liverpool. For the investigation of problems depending on the laws of probability, the theory of errors, and so on, familiarity with the higher mathematics is, of course, indispensable, but there is little doubt that even this knowledge will be forthcoming among the more studious members of our profession when the demand for such knowledge has been established.

OXALIC ACID IN FOODS.

FOR a long time it has been known that oxalic acid or oxalates were a normal constituent of many vegetable foods and some observers have found relatively small quantities in animal foods. There was a silly fear some years ago that tomatoes were poisonous, and suspicion was entertained that their consumption led somehow and vaguely to cancer, the suspicion seeming to receive support from the fact that they were found to contain oxalic acid. If the various foods which analysis has shown to contain oxalic acid or oxalates are to be banished from our dietary, then the following must go, while their use in the daily diet might be made to account just as scientifically for cancer as the use of tomatoes: cocoa, tea, pepper, spinach, rhubarb, gooseberries, bread, plums, figs, chocolate, chicory, potatoes, beet-root, beans, coffee, strawberries, carrots, cabbages, and celery. Rhubarb has been recently said to contain free oxalic acid in alarming quantities, and the public has been seriously advised to eschew this undoubtedly excellent and dietetically useful acid stalk. It is true to say that rhubarb contains oxalic acid, but cocoa contains twice as much, spinach half as much again, and tea and pepper a good deal more. If rhubarb is poisonous because of its oxalic acid, then tea and cocoa should be, weight for weight, considered more poisonous. Rhubarb contains 0·24 per cent. of oxalic acid, spinach 0·32 per cent., pepper 0·32 per cent., tea 0·37 per cent., and cocoa 0·45 per cent. Oxalic acid is, of course, poisonous, but statistics appear to show that the lethal dose averages about half an ounce, assuming that no prompt administration of remedies had been made. According to this the fatal dose of oxalic acid in rhubarb would be represented in about 12 pounds of the stalk, which, of course, is an impossible quantity for anyone to consume at a single sitting. But a large proportion of the oxalic acid exists, not only as such, but in the form of oxalate of lime, which is harmless, lime being used as an antidote in oxalic acid poisoning. The oxalic acid in cocoa exists almost entirely as oxalate of lime, and therefore its presence may be ignored on the score of harmfulness. Further, the oxalates are changed into innocuous compounds in the metabolic processes, about 80 cent. of the intake disappearing in this way. There are, it must be admitted, special cases in which care should be taken to exclude a diet which contains a constituent known to aggravate certain conditions. Rhubarb is therefore properly excluded from the diet of certain individuals, just as sugar is forbidden to those for whom the physician knows it is harmful. On the whole, however, the generality of persons is not likely to suffer any harm from the oxalic series contained in so many very familiar and widely used articles of food.

EPIDEMIC DROPSY IN CALCUTTA.

A SOMEWHAT mysterious malady has been epidemic in Calcutta, particularly during the last four months of 1909, diagnosed by some as a modified form of beri-beri and by others as "epidemic dropsy." The disease is not new to the city, for similar outbreaks occurred in 1878, 1879, 1901, and 1907. Dr. T. Frederick Pearse, the medical officer of health of Calcutta, has recently issued a report on the epidemic malady, discussing its incidence and probable nature. It appears that cases have been found in nearly every part of the city, and that all classes and castes, rich and poor, weak and robust, have been attacked. There have been more fatal cases among women than men, but infants and young children seem to have escaped. Hindus suffered in a larger proportion than Mahomedans. The precise number of persons attacked has not been ascertained, but it is believed to have been great. The total deaths certified in 1909 from the current epidemic disease were 433. In the previous outbreaks the case mortality rate was under 3 per cent. As regards causation, Dr. Pearse discusses two theories in his report: (1) that it is a food disease caused by the ingestion either of some adulterant or of some poison which has developed in the food; or (2) that it is an acute specific disease spread by infection directly from one human being to another. The popular notion in Calcutta was that the malady was due to some adulteration of mustard oil, which is a constant article of diet among the people. Careful inquiry and testing of some 200 samples of this oil gave, however, no support to this view. From the description given of the disease we are inclined to agree with Dr. Pearse that it is not beri-beri. Probably it is the ailment designated by Manson in his "Tropical Diseases" as epidemic dropsy, and described by him as a specific, epidemic, communicable disease, running its course in from three to six weeks, and characterised by the sudden appearance of anasarca, preceded in most instances by fever, vomiting, diarrhœa, or by irritation of the skin, and often accompanied by a rash, by fever of a mild remitting type, by disorder of the bowels, and by pronounced anæmia. Dr. Pearse, from his own observations, gives the incubation period as about three days. During the last few years the occurrence of epidemic dropsy, epidemic œdema, or angio-neurotic œdema has been reported in certain districts of India, and various causes have been assigned for the appearance of the disease. One observer blamed the bites of "a peculiar kind of mosquito," while another insisted that the bed bug acted as the transmitter of the malady. We regret to find from his report that Dr. Pearse has been submitted to what appears to us to have

been harsh and unfair criticism for his alleged want of activity in investigating the origin of the epidemic and for failing to institute rigorous measures for stopping its spread. Dr. Pearse, in defence, says that while fully realising the seriousness of the outbreak, and while applying such measures as appeared necessary, including disinfection, he found it impossible to impose vexatious restrictions, which would cost a good deal of money and cause a considerable amount of inconvenience to the inhabitants of the city, until more was definitely known of the nature of the malady, and until further investigation by suitably qualified scientific workers had been undertaken. With his own numerous and pressing duties to attend to, it was obviously impossible for him to institute a research on the subject, nor could he entrust it to any of his assistants, however competent they might be, unless the corporation provided and paid for duly skilled substitutes to do the routine work of the department; with their own daily duties to perform the members of Dr. Pearse's staff had no time in which to engage in independent original investigation. It is, in our opinion, most unfair that a highly competent and hard-working officer like Dr. Pearse should be subjected to such unjust and discouraging criticisms by irresponsible persons unacquainted with the difficulties of the subject. Happily, the Indian Government has come to the rescue; recognising the need for a comprehensive inquiry by a suitable expert into the prevalence of "epidemic dropsy," it has directed Captain E. D. W. Greig, I.M.S., to carry out a special investigation into the nature and causation of the disease.

PRACTICE BY BRITISH MEDICAL MEN ABROAD

THE General Medical Council has issued a useful report on "The Conditions under which Medical and Dental Practitioners Registered or Legally Qualified in their own Country may Practise Abroad,"[1] and as we are frequently asked for information upon the subject supplementary to that which we publish annually in our Students' Number, we are glad to bring it to the notice of our readers. The report is based upon answers to the following questions received from His Majesty's representatives and foreign governmental officials in 121 British Dominions and foreign countries: 1. What foreign qualifications entitle to practise legally, without passing any examination in your country or state? 2. What advantages (if any) are given to practitioners already registered, or entitled to be registered, in Great Britain? 3. (*a*) If no foreign qualifications are recognised, in what subjects must an examination be passed by a person who already possesses a qualification from a reputable foreign University body? (*b*) Can a foreigner be examined in his own language? 4. What documents must be produced by a person desirous of practising? 5. (*a*) What is the fee to be paid for the right to practise? (*b*) Has an annual fee to be paid and, if so, what is the amount? 6. To whom should application be made for further information and forms? Answers are also given to a similar set of questions sent out with regard to dental practice in the same countries and states. In the great majority of cases the answer to the first two questions is simply "None," although in some instances this reply is qualified. In Italy, for instance, we find that properly qualified foreign practitioners may practise amongst foreigners but not amongst natives without obtaining an Italian qualification. As is generally known, in most of the British dependencies and colonies the possession of a registrable British qualification confers a right to practise, but in some—e.g., in the Province of Ontario—this grace is not granted and a State examination has to be passed. In the preface to the report the warning is given that, as requirements are very liable to change, it will in every case be advisable for an intending emigrant before leaving home to write to the indicated local official for the details and necessary forms, so that there may be no trouble or disappointment on arrival abroad. We may add to this warning that it is always as well to obtain first-hand information as to the prospects of practice in any foreign place before giving up a certain living at home to proceed thither. The medical profession should be grateful to the General Medical Council for ordering this publication and to its compilers for the pains they have taken in producing it.

ALCOHOLIC BEVERAGES IN THE FAR EAST.

ATTENTION has been called to the increase in the consumption of alcohol in recent years amongst the Chinese in the Straits Settlements, following, it is alleged, the more stringent regulations imposed upon the opium traffic; and in view of the recent introduction of crude European spirit into those parts, it may therefore be of interest to review briefly the main varieties of native alcoholic beverages ordinarily consumed. Of these, probably the most familiar are "arrack" and "saké," "samshu" and "hocshu." "Arrack" is an ardent spirit procured from "toddy," the fermented juice of the "coco" and other palms, from rice, or from "jaggery," a coarse, dark-coloured sugar obtained from the sap of the "jaggery palm." It is made all over the Malay Archipelago, varies greatly in strength, tastes like sour beer, and is distinctly heady. It is the usual drink of "coolies." "Saké" is the national beverage of Japan. It has a peculiar flavour not comparable to any European drink, is made from fermented rice by an intricate process in winter time, and contains from 11 to 14 per cent. of alcohol. It is a necessary constituent of every ceremonial Japanese dinner, is served hot in little ampulla-like jars, and drunk with much formality from squat earless saké-cups containing approximately about 2 ounces. To the European palate it tastes sour at first, but a preference for it is readily acquired. Curiously enough, it has a much more powerful effect on the Japanese than on Europeans. A stronger variety, "shochu," contains from 20 to 50 per cent. of alcohol. Another form, "mirin," is more or less like a liqueur. The Chinese have two alcoholic drinks, "samshu" and "hocshu." "Samshu" is simply another name for "arrack," but "hocshu" is a much more aristocratic drink. We cannot describe it better than in the words of that inimitable old buccaneer, Dampier[1]: "This is a strong liquor, made of wheat, as I have been told. It looks like 'mum' (a peculiar kind of beer made from wheat malt) and tastes much like it, and is very pleasant and hearty. Our seamen love it mightily, and will lick their lips with it, for scarce a ship goes to China but the men come home fat with soaking the liquor, and bring stores of jars of it home with them." It is put up in small squat white jars, sealed with a wooden plug, covered with a thick mass of prepared clay extending half way down the neck. Connoisseurs are very careful to examine this plug, as the slightest crack allows the liquor to become sour. In recent years, however, European alcoholic beverages have been gradually superseding the native brews, and a very excellent lager beer, "Kirin," is now manufactured and much used in Japan. The Oriental, however, is an extremely abstemious person on the whole, and the native liquors do not lend themselves to debauchery. Unfortunately in recent years regularly increasing quantities of crude European "whiskies" and "brandies" are being shipped to Far Eastern ports, and though intended originally, no doubt, for the consumption of the European sailor, they are now increasingly used by the ubiquitous Chinese. There is

[1] Dampier's Voyages, fourth edition, vol. i., pp. 419-420.

no tax on alcohol in the Straits Settlements, and, as a consequence, these spirits are exceedingly cheap, so much so that one peculiarly virulent brand of "Fine Old Scotch Whisky," with the figure of a Highlander in full dress, and the motto, "Made in Germany," on the label, can be procured for 1*s.* a large bottle in Penang and Singapore. We do not know what it is that these bottles contain, but of their danger to health there can be no doubt. Even on the seasoned European sailor they have a most paralysing effect, men lying comatose sometimes for 36 hours after a debauch, giving colour to the idea that they have been "Shanghaied"; and on the more abstemious Oriental the results are even more pronounced. According to the account of Dr. W. G. Ellis, embodied in the "Straits Settlements Reports for 1908," alcoholic insanity of an "acute maniacal type" is not an infrequent sequela of such debauches amongst the Chinese. The symptoms are not those of fear, nocturnal hallucinations, or the ordinary well-known signs of delirium tremens, but rather tend towards grandiose delusions and fixed ideas of persecution. Recovery, moreover, is often delayed till from six weeks to two months after the primary attack. To the taste these crude spirits are exceedingly disagreeable, and were it not for the absence of excise duties they would probably therefore be unsaleable. It seems obvious, then, that in the interests of public health preventive measures should be devised against the habit; for though the Oriental is never likely to fall a victim to "fire-water" as the unseasoned Red Indian did, yet he is not by any means as case-hardened to alcohol as the average European. On the other hand, if stoppage of his opium, as Dr. Ellis suggests, drives him to seek unconsciousness in cheap alcohol, it will behove us to move cautiously lest in ridding him of one evil we leave him exposed to another undoubtedly greater.

MARCH AT HOME AND ABROAD.

THE weather of March of this year differed entirely from that of March, 1909, when it was cold, with much rain, sleet, and snow, and very little sunshine. The month which has just closed, on the contrary, was very dry, the total rainfall being much below the average in almost every part of the kingdom. Over the greater part of England it was less than 50 per cent. of the normal; one of the driest spots was Liverpool, where the percentage was only 37. Wet days were very rare; several days early in the month, some about the middle, and nearly all after the 19th were quite rainless. The mean temperature of the month was a little above the average, although there were scarcely any really warm afternoons such as sometimes occur to give a foretaste of early summer even during a much colder March. In the important matter of sunshine it was most generous, the excess on the average being very large. In London the total number of hours was 110, which is slightly more than an hour per day in excess of the figure allowed by an average March, while at Manchester, a city which never fails to take full advantage of any dull weather in its vicinity, the number of hours was only 16 less than in London. At several of the resorts on the south coast the figure amounted to nearly 200 hours, or more than six hours per day. Generally fine weather was also the rule on the Continent, and the temperature at the southern resorts showed the effect of the increasing altitude of the sun. At the Nice observatory the thermometer was about equal to that which may be expected in London at the beginning of May, and that at Lisbon was almost identical to the average for May at Ventnor. At Malta and Algiers, the warmest places represented in the table, the mean minimum temperature of the nights was as high as that usually experienced in June and July over the greater portion of England north of the Thames valley. The afternoons in such places as Malta, Rome, Palermo, Palma, and Lisbon were about as warm as the average afternoon in the south of England during May. The Scilly Islands enjoyed a higher night temperature than Biarritz and several other places in southern Europe, while the mean diurnal range of temperature was only 7 degrees. London differed little from Paris in its mean temperature, but its days were rather colder and its nights milder. Berlin was not at all cold for the time of year, but colder than any part of England except the elevated resort of Buxton. At Berlin the sheltered thermometer fell to freezing point or below it on 15 nights, at Paris on 13, and in London on 8.

PURPURA HÆMORRHAGICA DUE TO BENZOL POISONING.

L. Selling[1] of Baltimore reports three cases of purpura, two of them fatal, in girls employed as factory hands in a process which involved handling and inhalation of commercial benzol. An examination of the remaining 20 persons working in the same room discovered purpuric spots in four. In the two fatal cases hæmorrhages occurred under the skin and mucous membranes, varying in extent, but reaching considerable proportions. Examination of the blood disclosed a great fall in the number of red blood corpuscles, together with an absence of regenerative forms, a scantiness of platelets, a relative increase in mononuclear types of leucocyte, and a general leucopenia. The bone marrow was very poor in cells and there was no evidence of a hyperplastic reaction. A similar series of cases was reported by Santesson[2] from a Stockholm

[1] Johns Hopkins Hospital Bulletin, February, 1910.
[2] Archiv für Hygiene, xxi., p. 336.

manufactory of bicycle tyres where benzol was used as a solvent of rubber. By means of experiments in animals he proved that purpura could result from the continued absorption of benzol; and he was able to trace these effects to the principal constituent of commercial benzol—namely, benzene. Selling also arrived at the conclusion that benzene was the toxic agent in his cases, and although he could not produce purpura by injection of benzol into animals, he was able to bring about changes in the blood and bone marrow which were strikingly similar to those observed in his fatal cases. He concludes, therefore, that the cases he has reported were due to the action of benzol, or rather to the benzene of which benzol is largely composed.

A TELEGRAM from the Governor of Mauritius to the Secretary of State for the Colonies, received at the Colonial Office on April 1st, reported 2 cases of plague with 1 death during the week ending March 31st.

Dr. F. W. Mott will deliver the Oliver-Sharpey lectures at the Royal College of Physicians of London on April 22nd and 29th at 5 o'clock. He will take for his subject, "The Cerebro-spinal Fluid."

THE LIFE ASSURANCE OF WOMEN.

BY R. HINGSTON FOX, M.D. BRUX., M.R.C.P. LOND.,
PHYSICIAN TO THE FRIENDS PROVIDENT INSTITUTION.

A DISCUSSION on the Mortality of Female Assured Lives at the Institute of Actuaries in London on Dec. 20th last, introduced by Mr. C. W. Kenchington, F.I.A., of the Prudential Assurance Company, affords an opportunity of reviewing the question of the life assurance of women. It has become more frequent during the past 20 or 30 years for women to insure their lives. This is one effect of the changes which are taking place in our time in the development and occupations of the female sex. There can be no doubt that these changes are of a far-reaching nature. The census of 1901 revealed some of them, showing that 34·5 per cent. of all females over 15 years of age were engaged in some occupation; and as compared with the previous census nearly 50,000 women had to be transferred, it is stated, from the class of teachers to that of clerks.

Mr. Kenchington quoted on the medical aspect of the question papers by the present writer and by Dr. A. L. Galabin read before the Life Assurance Medical Officers' Association in 1898 and 1906 respectively.[1] We may first inquire, Has the mortality curve for female life altered in recent years? Down to the year 1890 this curve showed in England and Wales a generally lower range than that for male life, especially in infancy and after the age of 40 years. Between these periods there was to be noted in childhood and adolescence a slight excess over the male rate, due to the earlier onset of phthisis in girls than in boys. Further, during the child-bearing age the mortality nearly equalled that of men, since the deaths due to disorders connected with childbirth almost counterbalanced during this period the greater liability of males to death from violence and from disorders due to exposure and alcoholism. The mortality of childbirth, it may be noted in passing, was carefully investigated by Dr. Matthews Duncan[2] from various data, and conclusions were drawn from his tables that the average risk of death to the mother was about 1 in 200 births, whilst the risk in first labours was about 1 in 100. Mr. T. A. Coghlan in 1898[3] arrived at closely similar conclusions upon a wide basis of statistics in New South Wales. Mr. Kenchington has compiled a valuable table from the Registrar-General's returns, in which he has estimated the deaths resulting from all puerperal causes per 1000 live births. From this it appears that the rate which in 1881–85 was 4·94 per 1000 had diminished in 1906–07 to 3·93 per 1000. The "accidents of childbirth" (abortion, puerperal mania and convulsions, placenta prævia, &c.) had varied little, but great reduction (2·87 to 1·68) had taken place in "puerperal septic diseases." The risk from childbirth is therefore a diminishing one.

The principal changes in the death-rate of women during the past 18 years may be thus summed up: Firstly, the decline in the total death-rate from all causes has affected women more than men; secondly, the decrease in the mortality from tuberculous disease has been more considerable in the female sex; thirdly, improved hygiene and therapeutics have diminished the risks of childbirth; and fourthly, the apparent increase of cancer has had a somewhat adverse effect on female mortality, especially in the fifth and sixth decades of life, for it must be remembered that the liability to this disease begins about ten years earlier in women than in men, and that certain organs which belong to the female sex are especially prone to be attacked.

It results from these changes that the female death-rate throughout the whole of life has fallen, and that it has also fallen relatively to that of males. The more favourable range of mortality for the female sex which previously existed is therefore accentuated, although the curve still shows a very slight excess over the male rate in the period from 5 to 15 years of age.

If assured female lives were a fair sample of the population, it is plain from what has been said that these lives might be taken at slightly lower rates than those of men. But it is not so. Whilst men insure their lives almost as a matter of course, only a few women do so, although the number is increasing. The class of female assurers in the past has included many on whose lives policies were taken out on account of property or loans, not always a good class of life; whilst in some other cases the motive of weak health has operated, or in some way there has been a selection against the office. The "insurable interest" is often less clear than with men. "Medical selection" is, moreover, less effective than in the case of men, probably on account of the examination being less thorough, and perhaps also that women "more readily conceal material facts." A study of the female mortality during the earlier years after assurance has convinced Mr. Kenchington that the benefit of selection is for all practical purposes limited to the first five years after entry. In the case of men it lasts for a longer period. It has thus come to pass that the mortality of assured women has exceeded that of assured men up to about the age of 45 years. After that age it presents the more favourable range which is observed in the community at large. Most insurance offices therefore charge an extra premium on female lives.

The combined returns of the British assurance companies come down only to the year 1893. The changes which have since occurred in female assurance must be gleaned from data on a smaller scale. The number of female entrants was only 7·33 per cent. of the total in the experience of the 60 British offices (1863–1893). In Mr. Kenchington's large office it averaged during 1908 about 28 per cent. In another office the percentage was said by a speaker to have increased from 10 to 16. Not only have the numbers increased, but the conditions have changed. Of those women who formerly assured it is believed most were married. The present writer found that of 200 women entering in 1896–97 111 were spinsters. Mr. Kenchington reports that in 1908, of 1506 women women assuring 954 were spinsters. These figures accord with the experience of medical examiners to-day, before whom are coming many single women who are earning their living, and who generally take out endowment assurance policies. They are a good class of lives. Dr. Galabin in 1906 discussed the question how they can be equitably dealt with, for it is not quite reasonable that they should be mulcted for the special risks of their married sisters. It was suggested at the meeting on Dec. 20th that the extra rate for women should be imposed only on the married, and upon the marriage of those who had insured as spinsters. This would not be easy in practice and the rate must, of course, be larger than if applicable, as it usually is at present, to all women insurers. It is a pity that the collected experience of the offices does not distinguish between married and unmarried women. Amongst other points brought out by Mr. Kenchington was that of a

[1] R. Hingston Fox: On Female Lives, Transactions of the Life Assurance Medical Officers' Association. 1898–99, p. 49. Galabin: The Relative Mortality of Females, &c., Id., 1906–07, p. 21.
[2] Fecundity, Fertility, Sterility, 1866.
[3] Proceedings of the Royal Statistical Society.

"phenomenally heavy" mortality up to the age of 39 years of women insured under joint-life policies; this is ascribed to the child-bearing risk. Another point was the very favourable rate of mortality shown by female teachers, belonging to the Elementary School Teachers' Deferred Annuity Fund, during the period 1899–1906.

The defective character of the medical examination of women for insurance purposes has been felt strongly in America, where frauds in these cases appear to have been frequent,[4] and in view of the special risks connected with the child-bearing organs a routine examination of these organs has been advocated, but it may safely be said that this would not be tolerated by female insurers in England. Mr. Kenchington is inclined to dispense with medical examination for women, but this is surely a hazardous procedure, especially when it is remembered that women who seek insurance are a select class and not the bulk of the middle and upper class community as with men. Medical examination is already dispensed with for the double endowment assurance, and this form of policy has become increasingly popular amongst women of late years. Full particulars are given in the paper alluded to of the present practice of the offices in the matter of charging extras on female lives. From these it appears that the number of offices which take such lives without any extra rating has increased, and that amongst those which still impose such a rating the single extra premium has found more and more favour. Mr. Kenchington advocates a diminishing debt upon the policy, and there is no doubt that this form of rating scientifically meets the extra risk, since it bears most heavily on the early years when that risk is chiefly present. It may be useful in some cases, but would be declined by many proposers, for the true equivalent of even a small rating looks formidable in this shape. The method of making only a small proportion of the sum assured payable in the event of death occurring within the first year after entry is on a similar principle, and neither plan meets the needs of those who insure in connexion with financial risks.

Taking into account the increasing number of women assurers, so that they form a less restricted class, and the improved mortality returns, I think that they might now be taken on the same terms as men, excepting only that some provision should be made for the risk attending childbirth. The best provision is a single extra of 15*s.* or £1 per cent. payable by married women entering under the age of 40 years, and upon the marriage of those who entered in the single state. This should not be varied in special cases, favourable or unfavourable, which would average one another.

ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

I.

IN a leading article in THE LANCET of Jan. 29th we dealt with some interesting statistical considerations relative to the death-rate and infantile mortality of certain groups of towns, and we propose now to touch upon other matters of which the report in question treats.

Exotic Diseases.

With reference to exotic diseases, concerning which the usual summary is furnished by Dr. R. Bruce Low, it appears that while the actual diffusion of plague showed no signs of abating, there were hopeful indications that in India the mortality from the disease was on the decrease. But as regards cholera in India there was during 1908 a considerable increase on the number of deaths recorded in 1907 and no less than 600,000 natives died from it.

In connexion with this question of exotic diseases, it is of interest to turn to a summary furnished by Dr. Theodore Thomson with reference to the coast sanitary survey of England and Wales which was carried out by certain of the medical inspectors in 1907–08. As regards each port visited, the quality of general administration, the extent to which vessels were inspected, the hospital provision, and the presence or absence of a disinfecting apparatus are tersely indicated, and it must be said that in reference to the first two points the words "bad" and "none" occur with undesirable frequency, while as to facilities for effectual disinfection 52 districts had no satisfactory provision—a fact which bears hard upon the medical officers of health and inspectors of nuisances at those ports, as well as upon the masters of vessels.

Water-supplies.

Certain of the reports which have already been reviewed in the columns of THE LANCET are reprinted in the volume before us, and amongst these may be mentioned the report of Dr. Theodore Thomson and Mr. P. M. Crosthwaite on the conditions threatening the purity of the Cambridge water-supply. This report is of great interest, and it is well that it has been included in the annual volume, where it will be available for reference purposes. This question of the safety of chalk waters generally is, we are glad to see, engaging the attention of the medical department of the Board, as the extensive area of uncovered chalk in certain parts of the country and the large population supplied from wells in this formation render careful scrutiny of such supplies necessary, more especially when regard is paid to the manner in which building is extending over chalk areas where the chalk is not protected from pollution by any of the impassable Tertiary formations.

Attention is also being directed by the medical department to another important but often overlooked aspect of water-supplies, and that is their plumbo-solvency. From 1900 to 1902 Dr. A. C. Houston made some valuable investigations for the Local Government Board with respect to the action of moorland waters upon lead, and since these investigations increasing efforts have been made in many places to neutralise the acidity of peaty waters possessing plumbo-solvent power, while some authorities have endeavoured to enforce the substitution of iron for lead service pipes. But it has not, so far, been found practicable to prohibit the employment of lead pipes for the conveyance of soft water, and, moreover, substitutes such as glass-lined pipes and the like have not proved altogether satisfactory. As regards the effects still produced by peaty waters on the health of certain populations consuming them, it appears that although the cruder consequences such as wrist-drop, kidney disease, and abortion are less prevalent than heretofore, there are still being produced in some districts conditions such as lassitude, anæmia, and inability to work from the frequent ingestion of minute doses of lead, and it is clear that a not inconsiderable amount of lead-poisoning still escapes notice. A good example of oversight in this sense is furnished by Dr. A. Newsholme in his current report. The medical officer of health of the Rhondda urban district, which obtains its water from the Pontypridd supply, suspected that such water was causing lead-poisoning in the district, and consequently he inquired of all the medical practitioners whether any cases of lead-poisoning had come to their notice. As a result 29 negative replies were received. In the following year similar inquiries were made, the observation being added that several recent cases of lead-poisoning were apparently ascribable to the water-supply. This time 23 replies were received, which elicited the fact that 35 cases of lead-poisoning were under treatment. These circumstances point to the conclusion either that formerly cases of lead-poisoning were overlooked, or that the Pontypridd water is sometimes acid and sometimes neutral, according as to whether or not certain peaty "feeders" are flowing or dry. But the facts suggest, as Dr. Newsholme observes, that medical officers of health should draw the attention of medical practitioners to any public water-supply which may possess plumbo-solvent power, and the further question arises whether lead-poisoning due to the consumption of water should not be made notifiable.

Vaccination.

The rapid increase which is occurring all over the country in the number of unvaccinated children renders it not improbable that on the reappearance of small-pox in epidemic form there will take place what has been described as "panic vaccination"—that is to say, the public vaccinators will be literally besieged by persons who desire to be forthwith protected against the disease, with the result that their supply of lymph will be quite insufficient to meet the demand. In order to make provision for abnormal demands

[4] Dr. C. Lyman Greene, Medical Examiner for Life Insurance, second edition, 1905, p. 112.

it is necessary that the Government lymph laboratory shall possess such a store of lymph as to enable it to cope with an emergency, and with this view Dr. F. R. Blaxall and Mr. H. S. Fremlin have been carrying out investigations as to the effect of cold storage upon vaccine lymph. Fortunately, the results of their experiments seem to show that lymph can be exposed to a temperature of below freezing point for six months and then yield on vaccination a case success of 99·6 per cent. and an insertion success of 96·7 per cent.

Carrier Cases of Enteric Fever.

Dr. Theodore Thomson and Dr. J. C. G. Ledingham contribute to the report a memorandum as to the progress of their inquiries into the occurrence of carrier cases of enteric fever. With respect to the excretion of bacilli by persons who have recovered recently from the disease a number of persons are being kept under observation, but the information so far acquired is insufficient to justify inferences. As to the influence of carrier cases in causation of enteric fever, investigations have been made into nine outbreaks where the circumstances suggested the possible operation of a carrier. In five of such outbreaks no carrier was discovered, but this fact by no means proves that a carrier was not operative, inasmuch as the examination of the stools and urine of suspected persons may have coincided with an intermission of excretion of the bacillus typhosus by them. In the case of two of the remaining outbreaks, the events could not be ascribed to a carrier, but among the persons attacked there were two in one outbreak and one in the other who, after recovery, continued to excrete the specific bacilli. One case discharged from hospital on Nov. 21st, 1908, yielded bacilli on Jan. 11th, 1909, while another case whose temperature was normal by August 24th, 1908, yielded bacillus typhosus in her stools on Dec. 8th, 1908.

The treatment of carrier cases under the Board's supervision has so far been confined to the employment of vaccines and the administration of milk soured by lactic acid bacilli, but hitherto all attempts to limit discharge of bacteria either by urine or fæces have failed, and thus support is lent to the provisional statement, "once a carrier, always a carrier."

BRITISH MEDICAL BENEVOLENT FUND.

AT the March meeting of the committee 27 cases were considered and grants amounting to £253 voted to 23 of the applicants. Appended is an abstract of the cases relieved.

Widow, aged 48 years, of M.B. Durh. Endeavours to support herself by taking boarders, but has not been successful so far. Two children, aged 18 and 16 years, the latter at Epsom College. Relieved twice, £24. Voted £10.

M.D. Cantab., M.R.C.P., aged 72 years. Quite incapacitated by paralysis and dependent on a small weekly allowance from a son and 5*s.* a week as old age pension. Voted £12.

Daughter, aged 67 years, of late M.R.C.S., L.S.A. Lost part of the provision made by father through the failure of a bank, and the rest in the endeavour to establish a boarding house. Voted £12.

M.R.C.S., aged 65 years. Retired about ten years ago owing to ill-health, but lost all his savings through unfortunate investments, and now endeavours to support himself by taking lodgers. Voted £12.

Daughter, aged 52 years, of late M.D. Edin. Has a small weekly pension, but is incapacitated by serious illness and is unable to meet unavoidable expenses. Voted £10.

Wife, aged 36 years, of M.R.C.S., L.R.C.P., who for 18 months has been confined to a county lunatic asylum. No income; lets lodgings. Three children, aged 13 to 4 years. Relieved once, £5. Voted £10.

Widow, aged 61 years, of L.R.C.S., L.R.C.P. Irel. Provision made by husband lost through the failure of a bank, and applicant having bad health is now dependent on a sister obliged to earn her living as a companion. Relieved three times, £36. Voted £12.

Daughter, aged 55 years, of late L.R.C.P. Edin. Used to be a dressmaker and endeavoured to start on her own account but was unsuccessful and lost her savings. Receives a few shillings a week from a friend and earns a little occasionally by needlework. Health indifferent. Relieved five times, £46. Voted £6.

Widow, aged 65 years, of M.B., C.M. Glasgow. Is in very feeble health and practically dependent on the help given by this Fund and another charity. Only son is a signalman earning small wages. Relieved ten times, £114. Voted £10.

Widow, aged 86 years, of M.R.C.S., L.S.A. Only income a pension of £25 per annum from the United Kingdom Beneficent Association. Children only able to help with a few shillings occasionally. Has been bedridden for several years. Relieved once, £5. Voted £12.

Daughter, aged 61 years, of late M.R.C.S. Had to give up situation to nurse her mother and sister, both since deceased, and now endeavours to support herself by taking boarders. Relieved three times, £52. Voted £10.

Widow, aged 52 years, of L.R.C.P., L.R.C.S. Edin. No income; health very indifferent. Earns a few shillings a week as caretaker; no children. Relieved six times, £58. Voted £12.

Widow, aged 71 years, of M.R.C.S. Dependent on 5*s.* a week as old age pension and slight help from a daughter. Relieved 17 times, £183. Voted £12.

Widow, aged 52 years, of M.D. Edin. Capital used to pay husband's debts, and now takes charge of a branch surgery, living rent free. Children unable to help. Relieved four times, £40. Voted £12.

Daughter, aged 58 years, of late L.S.A. No income; endeavours to maintain herself by letting lodgings; health very feeble. Relieved twice, £22. Voted £12.

Widow, aged 59 years, of M.R.C.S. No income, and dependent on two sons who can ill afford to help. Relieved five times, £45. Voted £10.

Daughter, aged 40 years, of late M.D. Edin. No income; is a daily governess, but at present has no post. Relieved eight times, £32. Voted £5.

Widow, aged 85 years, of M.D. Aberd. No income; dependent on two daughters who are governesses. Relieved once, £18. Voted £18.

Daughter, aged 50 years, of late M.R.C.S. No income, and health will not allow of any occupation. Relieved once, £10. Voted £10.

Widow, aged 69 years, of M.R.C.S. Income £14 a year and receives occasional slight help from two sons, who can only support themselves with difficulty. Relieved once, £10. Voted £12.

Daughter, aged 53 years, of late M.R.C.S. No income, and owing to continual ill-health, which prevents employment, is dependent on small weekly allowance from sister. Relieved 12 times, £137. Voted £12.

Widow, aged 59 years, of M.B., C.M. Edin. Supported herself for some years after husband's death by taking charge of mental cases, but is now incapacitated by heart disease and dependent on a son, whose earnings are small. Relieved six times, £72. Voted £12.

Widow, aged 36 years, of M.R.C.S. Quite unprovided for at husband's death a couple of years ago and obliged to keep a small home for the sake of the children. Slight help from friends. Relieved twice, £15. Voted £10.

Contributions may be sent to the honorary treasurer, Dr. Samuel West, 15, Wimpole-street, London, W.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 7th, 1832.

EXTRAORDINARY NARRATIVE.[1]

[Under the above heading a letter appears at page 441 of our present volume, written by Mr. HOARE, a most respectable surgeon of Warminster, detailing particulars of a young man of the name of Higgins, who, though fully endowed with the power of speech, would never speak to his father, nor, as then believed by Mr. HOARE, to any other male person. We this week insert a further communication from that gentleman on the subject, the public press in his neighbourhood having, as he observes, treated the statement alluded to as too strange to be credible.]

To the Editor of THE LANCET.

SIR,—My communication (see LANCET, December 24, 1831) respecting the young man of the name of Higgins having occasioned many inquiries, much sarcastic observation, and many expressions of incredulity, I took the liberty of writing to the Rev. Dr. Colston on the subject, who has kindly favoured me with the following circumstantial reply. This, if not sufficient to convince the incredulous, will at least exonerate me from the imputation of having published an extraordinary statement on light grounds. I am, Sir,

Your obedient servant,

JOHN HOARE, Surgeon.

Warminster, March 17, 1832.

Lydford Rectory, Somerton,
March 4th, 1832.

"SIR,—Immediately on the receipt of your letter I sent for Eli Higgins, a tenant of mine, and the man who has excited so much interest from his inability to speak to persons generally. It is true he never was able to speak to his father, who resorted both to violent and kind means to induce him to do so, without effect. With his mother and sisters he frequently conversed without any extraordinary effort, and these were the only females with whom he ever held conversation; but he admitted, on my examining him minutely on the subject, that he had spoken to the Rev. Mr. Bowen, of Bath, and Mr. Beauchamp, a land surveyor, of West Pennard, in this county, about four years since; but he was unable to account for this exception, as he wished much to speak to every one, more particularly his father, who has been dead nearly six months. After a lapse of three days he could speak with fluency to every one, and immediately after the funeral of his father he called on me to take the small estate that had been occupied by him, and entered fully into conversation; which greatly astonished me, as I have known him from his earliest days,

[1] Vide "Looking Back" in THE LANCET of Dec. 25th, 1909, p. 1832, and "Notes, Short Comments, &c.," in THE LANCET of Jan. 15th, 1910, p. 217.

and made many attempts to get him to speak to me; once in particular, wishing to know the hour of the day, I asked him for his watch, which he gave me, and I threatened to keep it if he would not ask for it, but in vain. He admits from what he had heard, that he was strongly impressed with the idea that on the death of his father he should have power to address every one without difficulty, which has proved to be the case. He had heard of the rash vow made by his parent when his mother was pregnant with him, that if the child were a girl he would never speak to it, but he could not attest to the truth of this from any authority but general report. Eli's appearance is delicate, and does not indicate strength. There is something very peculiar in his manner of using his mouth when he speaks, and the length of his jaw, from the point of his ear to his chin, is very striking; his voice is pleasing, and his manner of conversation sensible for his station in life. He is a hard-working, industrious man, and has always exerted himself to the utmost to promote his father's interest. You may make use of these particulars in any manner you please, and I remain, Sir, yours faithfully,

"W. H. COLSTON.

"To John Hoare, Esq., Surgeon,
Warminster, Wilts.

"Below is the writing of Higgins, which I thought might be interesting to you.

"'Eli Higgins Aged 35 years in the parish of Baltonsborough in County of Somerset.'"

MEDICINE AND THE LAW.

The Liability of Local Authorities for Unsuccessful Prosecutions under the Public Health Act, 1875: Hobbs v. *Winchester Corporation.*

Mr. Justice Channell has recently given judgment in an action of considerable importance to local authorities and to vendors of food, brought for the purpose of enforcing an award made in accordance with the Public Health Act, 1875. As the learned judge made express reference to the probability that his decision would be submitted to the consideration of the Court of Appeal, the facts are best stated without comment so far as they illustrate the point at issue. The plaintiff, a butcher, furnished meat at the Winchester Barracks under a contract which imposed strict conditions in respect of any heifer or cow-beef supplied. It was not to be from an animal under two or above four years old and no portion of the udder was to be cut away. Two fore-quarters, one complete hind-quarter, and part of another all coming from one animal above the specified age and sent without the udder were condemned by the military authorities upon a certain occasion, and so far as the military contract was concerned penalties provided under it were exacted as to which no question of the propriety of their enforcement was raised. The attention, however, of the medical officer of health was also called to the meat, which was removed by him and was duly ordered by a magistrate to be destroyed, after which a prosecution was instituted against the butcher. This prosecution, instituted by the Corporation of the City of Winchester, was dismissed by the bench, and the defendant Hobbs took proceedings under the 308th section of the Public Health Act, 1875, to have the damage which he had sustained through it assessed by an arbitrator. The arbitrator, Mr. Radcliffe, K.C., found among other facts that one fore-quarter only of the meat was unfit for human food when seized, and that Hobbs (defendant to the summons and plaintiff in the action) did not know when the meat was delivered that any part of it was unfit for food, that his servants did not know it, and that neither he nor his servants could have discovered its condition by any examination which he or they could reasonably have been expected to make. Mr. Radcliffe awarded as damages a sum in respect of the termination of a contract with the War Office, which, however, was not claimed in the action, and also the costs to which Hobbs had been put in defending himself, amounting to £118, and a further sum of £800 for general damage to trade and business owing to the prosecution. In order to obtain these two sums for costs and damages the plaintiff Hobbs had to bring them within the terms of the 308th section of the Public Health Act already referred to, which provides compensation to be settled by arbitration "where any person sustains any damage by reason of the exercise of any of the powers of this Act in relation to any matter as to which he is not himself in default." The "exercise of powers under the Act," it was argued on behalf of the corporation, consisted in seizing the meat and taking it before the magistrate for destruction under the 114th section of the Act, and it was only for the loss thus entailed that the 308th section gave compensation, when there was no "default" on the part of the person damaged by it. Against this view there is a decision of the Court of Appeal (Walsham *v.* Brighouse Corporation, 1899, 2 Q.B. 286), in which costs incurred through a prosecution were allowed as damages against a corporation on a parallel occasion, and it was argued that both the £800, general damages, and the costs must equally be regarded as the result of the exercise by the defendants of the powers given by the Act. Mr. Justice Channell intimated that but for the judgment in Walsham *v.* Brighouse Corporation he might have held that the costs to which the plaintiff had been put followed not from the fact of the seizure, but from the institution of the prosecution. He was, however, of the opinion that the decision of the Court of Appeal governed the case before him both with regard to the costs and the damages. He commented upon the large sum awarded in respect of the latter, but said that seeing that that was the amount found by the arbitrator, and knowing who he was, he had no doubt the finding was correct. He therefore gave judgment for the two sums mentioned, granting a stay of execution in view of a possible appeal. It will be seen from the above that the point thus raised is of great importance to both parties to the case, as well as to potential parties to similar litigation, whether local authorities or food purveyors, the difference being considerable between compensation, measured by the value of meat seized and destroyed, and the recovery of substantial damages and costs of defence in respect of an unsuccessful prosecution.

Public Health.

REPORTS OF INSPECTORS OF THE MEDICAL DEPARTMENT OF THE LOCAL GOVERNMENT BOARD.

On the Sanitary Circumstances of the Axbridge Rural District, Somerset, by Dr. REGINALD FARRAR.[1]—Dr. Farrar directs attention to the unsatisfactory character of the water-supplies at present available in many of the parishes and villages of this rural district. The district is bounded on the west by the Bristol Channel, and contains two extensive tracts of flat alluvial land, separated from each other by the Mendip Hills, the western end of which cuts through the Axbridge district. The hill areas consist principally of carboniferous limestone, and at the base of the hills an abundance of water can be obtained from springs. On the upper slopes, however, water is scarce, and the inhabitants either depend on rain water caught from the roofs or have to go considerable distances down home to fetch water. Some private houses on the higher levels are now being supplied by windmill pumps, and this method is recommended for more general adoption. The greatest difficulty in the matter of water-supply is found by the villages on the marsh lands. Here the ground water is brackish and impure, and quite unfit for drinking purposes. The people use roof water, or rain water caught in shallow pits, and in some cases resort to "rhynes" or dykes, which are liable to serious pollution by the drainage of farms, by sheep-washing, and by other means. Many public wells have been shown to yield polluted water. In September of last year an outbreak of enteric fever involving 13 cases occurred in the village of Banwell, and was traced to the water of one of these wells. The danger of water which is impure and deficient in quantity is not confined to the inhabitants of the district. A large dairy in Banwell parish obtains the whole of its water for washing churns and making butter from a sewage-laden "rhyne" which runs near the dairy. The magnitude of the mischief which might be done if this "rhyne" became specifically infected with the germs of enteric fever will be understood when it is realised that 1000 gallons of milk are sold daily from this dairy. Apart from the question of risk to health, these unsatisfactory water-supplies form a serious drawback to the general development of the district. Dr. Farrar urges that the problem should be faced boldly and that the district council should be prepared to obtain a loan for the sum, estimated at £30,000, necessary for a comprehensive scheme of supply to the parishes concerned. This sum

[1] Reports to the Local Government Board on Public Health and Medical Subjects. New Series, No. 21. London: Wyman and Sons, Fetter-lane; Edinburgh: Oliver and Boyd; Dublin: E. Ponsonby. Price 3*d*.

is less than a year's assessable value of these parishes, and in the light of this report it is difficult to imagine a better or more necessary investment. It is to be hoped that the Local Government Board will lose no time in pressing this essential sanitary improvement on the local authorities.

On the Sanitary Circumstances and Administration of the Ramsey Urban District, with Special Reference to the Prevalence of Scarlatina, by Dr. R. D. SWEETING.[2]—The district of Ramsey, in the county of Huntingdon, comprises areas of fen land in which, as in the marsh lands of Axbridge, there is considerable difficulty in obtaining a safe and satisfactory supply of drinking water. The town of Ramsey itself, with a population of about 2600, is chiefly supplied by impounding the water from ditches which drain ground liable to human and animal excremental pollution. This water is received into a pit, at the inlet of which some attempt at filtration is made; it passes thence through a coarse filter to the well from which it is distributed. The filtration is inadequate, and the impurity of the water is locally recognised, the district council recommending that it should be boiled before drinking. Other supplies, obtained from public and private wells, are open to serious objection. The provision of a safe and sufficient public supply is not an easy matter, owing to the physical and geological conditions in the neighbourhood. Dr. Sweeting suggests boring, under expert advice, and alternatively other methods which, although somewhat costly, appear practicable in the circumstances of the district. In another section of the report Dr. Sweeting deals with scarlet fever prevalence, a subject on which special representations had been made by Dr. J. B. Wilkinson, the consulting medical officer of health of the county. In the first seven months of 1909 there were 128 notifications of scarlet fever in the whole district, which has a population of about 4900, and seven deaths occurred. This is equal to a case rate of about 44 per 1000 per annum, which must be regarded as constituting an exceptionally severe epidemic at the present day. 74 families were affected, of which 44 contributed single cases. Dr. Sweeting is inclined to attribute the persistent and severe prevalence of the disease largely to sustained personal infection and the absence of hospital isolation. In 1909, as compared with the two previous years, scarlet fever in Ramsey showed an exceptionally high fatality at ages between 15 and 30 years. It is also noteworthy that in three of the four fatal cases in this age period there were pronounced cerebral symptoms with suppression of rash. There is some indication that the disease is becoming generally more malignant in type in this district, and this may perhaps be attributed in part to the various insanitary conditions prevailing in Ramsey exercising a predisposing influence to this fever by lowering the bodily resistance to it.

On the Sanitary Circumstances and Administration of the Rural District of Easington, by Dr. R. W. JOHNSTONE.[3]—This report relates to a populous coal-mining district in the county of Durham, the conditions of which were investigated by the Local Government Board in consequence of complaint by the county council of neglect by the district council of various sanitary duties, particularly in the matter of housing of the working classes and construction of sewers. The great majority of the houses are owned by the colliery companies and let to the colliers rent-free as part of their wages. When there is no "colliery house" available, an allowance in money is made by the company, but this is seldom sufficient to pay the rent, and has the further disadvantage, from the collier's point of view, that it ceases when work is stopped by disputes or strikes. Most of the dwellings are rated under £8 a year, the companies paying the rates for the houses owned by them. Some of the colliery houses are very good, but a great many old dwellings exist, of which large numbers are dilapidated, damp, and faulty in construction. Where pits have been shut down the houses in the neighbourhood have fallen into disrepair, but nevertheless in many cases remain occupied. Overcrowding of persons in the dwellings is not infrequent. This is largely owing to the custom of taking lodgers, but is also due to insufficiency of houses in the vicinity of the collieries. Speaking generally, the colliers keep the inside of their houses with great neatness and cleanliness. "It is only when the dwelling itself is so damp and dilapidated as to dishearten the occupier that an unclean interior is found." Dr. Johnstone gives various examples of the faulty principles on which many of the cottages have been built in the past, and their bad results. There seems no reason, even in the matter of economy, for these conditions to be continued, and it is very necessary that the housing of the district should be systematically inspected, so that the worst, at any rate, of these dwellings may be suitably dealt with. This process should be facilitated by the provisions of the new Housing and Town Planning Act. The report gives prominence to the condition of the "back streets," which is one of the worst features of many of the colliery villages in Northumberland and Durham. The "front streets," which are usually more or less made up, channelled, and drained, are devoted to clothes-lines for hanging out washing, but otherwise are usually a desert so far as human use or occupation is concerned. The back streets, on the other hand, serve as the means of access to the houses and as the children's playground. In them are also generally situated the privy middens, during the scavenging of which the ground around is liable to frequent fouling. These back streets are hardly ever made up beyond the laying down of some ashes over the rough clay, and in wet weather are usually quagmires. From a health point of view the condition of these streets is much more important than that of the front ones. Dr. Johnstone considers that in general the district council has not been inactive in the sanitary administration of the area under its charge, but that housing reforms and certain other matters would have made less progress had it not been for the pressure exercised by the county authorities. Attention is directed in the report to various important reforms which should now be undertaken.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

British Guiana: Report of the Surgeon-General, 1908–09.—We have received from the Government printers at Georgetown, Demerara, a copy of the report of Dr. J. E. Godfrey, the Surgeon-General of the colony of British Guiana. The greater part of this document is concerned with administrative details respecting the local public hospitals and dispensaries, as well as respecting the asylums for lunatics and for lepers. An interesting and instructive section of the report deals with the public health of the colony, and it is to this section more especially that the present notice relates. The Surgeon-General reports that the colony has been free from any dangerous infectious or contagious disease throughout the year, although the existence of yellow fever in Barbados and of plague in Trinidad was still the cause of much anxiety. The birth-rate in 1908 was equal to 27·3 per 1000, and was lower by 1 per 1000 than in the preceding year. The deaths in 1908 exceeded the births by more than 1000, and were equal to a rate of 30·8 per 1000 of the population, or 6·1 per 1000 less than in the year immediately preceding, when the deaths exceeded the births by 2656. On this point the Surgeon-General remarks that "while it is gratifying to record that there was a very appreciable decrease in the death-rate, it is not pleasant to have to call attention to the very large fall in the birth-rate from 32·9 in 1906 to 27·3 in 1908; but such are the facts as revealed by the statistics of the Registrar-General." There appears to be no diminution in the sacrifice of infant life in the colony. According to the report we learn that of the 8299 infants born within the year under notice not fewer than 1644 died before completing their first year of life. Infantile mortality, measured by the proportion of deaths under one year to births registered, was therefore equal to 198 per 1000, as against 256 per 1000 in the preceding year. As in previous years, attention is again drawn to the prevalence of tuberculosis in the colony. During the year it caused 7·4 per cent. of the total mortality in British Guiana and 8·4 per cent. in Georgetown. Dr. Godfrey speaks appreciatively of the work done by the Society for the Prevention and Treatment of Tuberculosis. From personal experience he testifies to the fact that the operations of the society are being extended in the colony with beneficial results to the community generally. So far, the society's work has been effected independently of Government subsidy in any form, and it is to be hoped that want of funds in the future will not be allowed to hamper the good work now being done. The Surgeon-General asserts that this matter is one of vital importance to the colony, and declares it to be the duty of

his fellow colonists to support the society in the execution and extension of its work. In the prophylaxis and treatment of tuberculosis difficulties are encountered in the colony almost identical with those with which we are familiar at home. Dr. E. D. Rowland, resident medical officer of the Georgetown Public Hospital, speaks of the results of institution treatment of pulmonary tuberculosis as extremely disappointing. The cases come in, for the most part, in a hopeless condition, but the few patients who apply in an early stage almost invariably improve under treatment; their temperature soon falls to normal and they put on weight rapidly. Nevertheless, in spite of entreaty to continue treatment, these patients usually insist on leaving hospital the moment they feel stronger, only to return in a few months in a sadly worse, if not a hopeless, condition. The Surgeon-General gives an interesting account of the new treatment of leprosy by Nastin, as carried out in the colony by Professor Deycke of Hamburg; and although it is too early as yet to speak definitely on the point he speaks of the results as distinctly encouraging. We hope to hear further details of this important treatment. Great attention is being paid in the colony to the active treatment of ankylostomiasis. Although the mortality from this disease is not high, the loss to the labouring classes from the undermining of health by this parasite is stated to be enormous. The people themselves take intelligent interest in their cases and realise the importance of "getting rid of the belly worms."

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 76 of the largest English towns 8159 births and 4614 deaths were registered during the week ending April 2nd. The annual rate of mortality in these towns, which had been equal to 13·5 and 13·9 per 1000 in the two preceding weeks, further rose to 14·4 in the week under notice. During the 13 weeks of the past quarter the annual death-rate in these towns did not exceed 15·0 per 1000, and was 3·0 below the average rate in these towns in the four preceding corresponding quarters; in London the mean rate during last quarter was equal to 14·9 per 1000. The lowest reported annual rates of mortality in the 76 towns during last week were 8·0 in East Ham, 8·2 in Willesden, 8·3 in Halifax, and 8·5 in Walthamstow; the rates in the other towns ranged upwards, however, to 19·4 in Plymouth, 19·7 in Liverpool, and 24·3 both in Merthyr Tydfil and in Swansea. In London the recorded death-rate last week did not exceed 14·5 per 1000. The 4614 deaths registered in the 76 towns during the week showed a further increase of 166 upon the low numbers in the two previous weeks, and included 332 which were referred to the principal epidemic diseases, against 335 and 317 in the two preceding weeks; of these 332 deaths, 139 resulted from whooping-cough, 93 from measles, 35 from diphtheria, 3 0 from diarrhœa, 25 from scarlet fever, and 10 from enteric fever, but not one from small-pox. The mean annual rate of mortality in the 76 towns during the week from these epidemic diseases was equal to 1·0 per 1000, corresponding with the rate in each of the two preceding weeks. No death from any of these epidemic diseases was registered last week in Southampton, Oldham, Preston, East Ham, Brighton, or in 13 other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·7 per 1000 in Ipswich, 3·3 in Merthyr Tydfil, 3·7 in Hanley, and 4·4 in Burnley. The fatal cases of whooping-cough in the 76 towns, which had been 134 in each of the two previous weeks, were 139 in the week under notice, and caused annual death-rates equal to 1·3 in Birkenhead and in Newport, 1·5 in Hastings and in Wolverhampton, and 2·5 in Devonport. The deaths from measles, which had been 84 and 78 in the two previous weeks, rose to 93 last week; the highest death-rates from this disease during the week were 2·2 in Hanley and in Bootle, 2·6 in Merthyr Tydfil, and 2·9 in Burnley. The 35 deaths referred to diphtheria showed a decline of 7 from the number in the previous week, and included 11 in London and its suburban districts, 3 in Hull, 3 in Newcastle-on-Tyne, and 3 in Manchester and Salford. The 30 deaths attributed to diarrhœa exceeded the low number in the previous week, but were below the average. The 25 fatal cases of scarlet fever showed a further decline from recent weekly numbers; 3 were recorded both in Birmingham and in Liverpool. Only 10 deaths in the 76 towns were referred to enteric fever, a lower number than in any previous week of this year. The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily declined in the 24 preceding weeks from 2819 to 1650, had further fallen to 1611 on April 2nd; 158 new cases of this disease were admitted to these hospitals during last week, against 199, 180, and 173 in the three preceding weeks. The Metropolitan Asylums Hospitals contained no case of small-pox on April 2nd. Of the 1354 deaths registered in London during the week under notice 310 were referred to pneumonia and other diseases of the respiratory system, showing a further increase of 49 upon the low numbers in the two previous weeks; they were, however, 39 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 36, or 0·8 per cent., of the deaths registered in the 76 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death during the week were duly certified in Leeds, Bristol, Bradford, Newcastle-on-Tyne, Hull, Leicester, and in 50 other smaller towns; the 36 uncertified causes of death in the 76 towns included 7 in Liverpool, 6 in Birmingham, and 3 in St. Helens.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 930 births and 656 deaths were registered during the week ending April 2nd. The annual rate of mortality in these towns, which had been equal to 17·2, 16·9, and 15·3 per 1000 in the three preceding weeks, rose again to 18·1 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these towns averaged 17·5 per 1000, and exceeded by 2·5 the mean rate during the same period in the 76 largest English towns. The annual death-rates during last week in these eight Scotch towns ranged from 14·3 and 15·9 in Aberdeen and Edinburgh to 25·4 in Dundee and 26·9 in Greenock. The 656 deaths from all causes in the eight towns during the week showed an increase of 100 upon the low numbers in the previous week, and included 82 which were referred to the principal epidemic diseases, against 72 and 77 in the two preceding weeks. These 82 deaths were equal to an annual rate of 2·3 per 1000; the mean death-rate from the same diseases in the 76 English towns last week did not exceed 1·0 per 1000. These 82 deaths in the Scotch towns included 43 from measles, 25 from diarrhœa, 7 from whooping-cough, 4 from scarlet fever, 2 from diphtheria, and 1 from "fever," but not one from small-pox. The fatal cases of measles in the eight towns, which had been 35 and 45 in the two previous weeks, were 43 last week, of which 16 occurred in Dundee, 10 in Glasgow, 7 in Greenock, 4 both in Edinburgh and in Leith, and 2 in Paisley. The 25 deaths attributed to diarrhœa showed a marked increase upon the numbers in recent weeks, and included 10 in Glasgow, 5 in Dundee, 4 in Edinburgh, 3 in Leith, and 2 in Greenock. Of the 7 fatal cases of whooping-cough 4 were returned in Glasgow and 2 in Greenock. The 4 deaths from scarlet fever included 2 in Glasgow; and the fatal case of "fever" also occurred in Glasgow. The deaths in the eight towns referred to diseases of the respiratory system, which had been 100 in each of the two previous weeks, rose to 122 in the week under notice, but were 41 below the number in the corresponding week of last year. The causes of 23, or 3·5 per cent., of the deaths in the eight towns were not certified or not stated; in the 76 English towns the proportion of uncertified causes of death did not exceed 0·8 per cent.

HEALTH OF IRISH TOWNS.

In 22 town districts of Ireland, having an estimated population of 1,151,790 persons, 661 births and 457 deaths were registered during the week ending April 2nd. The mean annual rate of mortality in these towns, which had been equal to 22·0, 19·0, and 21·1 per 1000 in the three preceding weeks, declined again to 20·7 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these Irish towns averaged 21·8 per 1000, whereas the mean rate during the same period did not exceed 15·0 in the 76 largest English towns and 17·5 in the eight principal Scotch towns. The annual death-rate

last week was equal to 19·8 in Dublin, 18·4 in Belfast, 32·9 in Cork, 13·2 in Londonderry, 23·2 in Limerick, and 19·5 in Waterford; the mean annual death-rate last week in the 16 smallest of the Irish towns was equal to 24·7 per 1000. The 457 deaths from all causes in the 22 town districts last week showed a decline of 9 from the number returned in the previous week, and included 26 which were referred to the principal epidemic diseases, corresponding with the number in the previous week; these 26 deaths were equal to an annual rate of 1·2 per 1000; in the 76 English towns the mean rate last week from the same diseases did not exceed 1·0 per 1000, while in the eight Scotch towns it was equal to 2·3. The 26 deaths from these diseases in the Irish towns last week included 8 from whooping-cough, 6 from measles, 5 from diarrhœa, 3 from diphtheria, 2 from scarlet fever, and 2 from enteric fever, but not one from small-pox. The 8 fatal cases of whooping-cough showed a considerable decline from the numbers in recent weeks; they included 6 in Belfast and 1 in Dublin. All the 6 deaths from measles, the 2 from scarlet fever, and 1 each from diphtheria, enteric fever, and diarrhœa occurred in Belfast. A fatal case of enteric fever was also returned in Dublin. The deaths in the 22 town districts referred to pneumonia and other diseases of the respiratory system, which had been 104 and 107 in the two preceding weeks, declined last week to 102. The causes of 20, or 4·4 per cent., of the deaths registered last week in the Irish towns were not certified; in the 76 English towns the proportion of uncertified causes of death last week did not exceed 0·8 per cent., while in the eight principal Scotch towns it was equal to 3·5 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Fleet-Surgeon A. E. Kelsey has been placed on the Retired List (to date March 29th).

The following appointments are notified: Staff-Surgeons: E. S. Tuck, to the *Victorious*, and C. B. Fairbank, to the *Flora*. Surgeons: W. C. B. Smith to the *Triton*, and H. F. Briggs to the *Leander*. Civil Practitioner: W. J. O'Doherty to be Surgeon and Agent at Teelin and Malinmore (Glen Bay).

ROYAL ARMY MEDICAL CORPS.

Brevet-Colonel F. J. Lambkin, lecturer in syphilology, Royal Army Medical College, proceeds to South Africa next month. Lieutenant-Colonel E. J. E. Risk, from Bloemfontein, has been selected for the appointment of Administrative Medical Officer of the Belfast District. Lieutenant-Colonel S. R. Wills, on arrival in India, has been appointed to command the station hospital, Agra. Lieutenant-Colonel A. A. Sutton, D.S.O., from Woolwich, has been appointed Senior Medical Officer, West Coast of Africa, vice Major F. J. W. Porter, D.S.O., tour expired. Lieutenant-Colonel D. M. O'Callaghan, from Kuldana, has been posted to Aldershot. Lieutenant-Colonel R. H. Penton, D.S.O., from York, has been posted to Poona. Lieutenant-Colonel P. C. H. Gordon has arrived home from India. Major C. A. Stone and Major A. L. Way have been selected for increased rate of pay under Article 317 of the Royal Warrant. Major A. J. Luther, Major St. J. B. Killery, and Major G. B. Carter have arrived home from India on completion of a tour of foreign service. Major R. J. Copeland has been transferred from the Seventh (Meerut) Division to the Eighth (Lucknow) Division and appointed to command the station hospital at Darjeeling. Major T. McCulloch, from Lebong, has been appointed to command the station hospital at Mandalay. Major J. D. Alexander has been appointed to command the station hospital at Thayetmyo. Major E. M. Hassard, from Shorncliffe, has been posted to Lahore. Major M. MacG. Rattray, from Bangalore, has been posted to Gravesend. Major H. W. Grattan has been appointed Sanitary Officer of the Eighth (Lucknow) Division. Major F. W. Hardy, from London, has been appointed Sanitary Officer, Northern Area, Eastern Command, vice Captain Tilbury-Brown, who has proceeded to Burma. Captain T. E. Harty, Captain R. R. Lewis, and Captain D. P. Johnstone have arrived home, tour expired, from India, and Captain F. B. Delavoye has arrived home from Bermuda. Captain G. M. Goldsmith has been appointed Staff-Surgeon, Divisional Headquarters, Burma. Captain R. N. Woodley has been transferred from Cork District to Bulford Camp. Captain Ievers has joined at Wynberg. Captain D. S. Skelton has been posted to the Southern Command. Captain H. Simson has been appointed a specialist in the prevention of disease and placed in charge of the Brigade Laboratory at Ahmednagar. Captain E. P. Hewitt, from Norwich, has joined Secunderabad station hospital for duty. Captain E. W. Siberry, from Aldershot, has been posted to Pretoria. Captain L. M. Purser, from Colchester, has been appointed to the station hospital at Sialkot. Captain R. F. M. Fawcett has been transferred from Gosport to Bulford Camp. Lieutenant J. S. McCombe, Lieutenant W. J. Tobin, Lieutenant R. O'Kelly, and Lieutenant C. Ryles have embarked for India. Lieutenant M. Leckie has been seconded for service with the Egyptian Army. Lieutenant W. I. Thompson has been transferred from Naini Tal to Lucknow, and Lieutenant F. H. M. Chapman from Darjeeling to Lebong. Lieutenant M. P. Leahy, on arrival in India, has been posted to Poona.

INDIAN MEDICAL SERVICE.

Colonel T. E. L. Bate, C.I.E., has been nominated by the Lieutenant-Governor of the Punjab as a member of the Legislative Council of the Province for the purpose of making laws and regulations, vice the Hon. Mr. W. F. Fenton. Lieutenant-Colonel C. N. Bensley has been granted one year's leave. Lieutenant-Colonel C. E. Sunder, civil surgeon, of Gaya, has been appointed a First-class Civil Surgeon. Lieutenant-Colonel S. C. Sarkies has been appointed District Medical and Sanitary Officer and Superintendent of the Reformatory School at Chingleput. Lieutenant-Colonel R. B. Roe, Civil Surgeon and Superintendent of the Lunatic Asylum at Nagpore, has been appointed to officiate as Inspector-General of Civil Hospitals in the Central Provinces. Lieutenant-Colonel L. G. Fisher has been appointed an officiating First-class Civil Surgeon, vice Lieutenant-Colonel J. Morewood, who has been confirmed in his appointment as a First-class Civil Surgeon, with effect from Dec. 14th, 1909. Lieutenant-Colonel D. S. E Bain has been permitted to retire from April 5th. Major J. Grant, Bombay, has had his leave extended by six months. Major Mulvany, officiating Inspector-General of Prisons, Bengal Presidency, has been granted combined leave for one year, four months, and 24 days. Major A. C. Elliott has had his leave extended for six months on medical certificate. Major Bamfield has been posted to the Punjab for duty under the Home Department of the Government of India. Major J. Jackson and Major R. D. Green have arrived home from India on leave. Captain W. Tarr, Officiating Civil Surgeon, Chanda, officiates as Superintendent of the Central Jail, Jubbulpore, during the absence on leave of Major C. H. Bensley. Captain R. K. White has been appointed to the substantive medical charge of the 18th Infantry, vice Captain A. T. Pridham. Captain H. Hallilay, civil surgeon at Dharmsala, has been transferred to Lyallpur. Captain Leslie has been selected for appointment in the Jail Department. Captain W. McM. Pearson, civil surgeon at Banda, United Provinces, has been granted privilege leave, combined with study leave and furlough, for 18 months, with effect from March 16th. Captain Scott, civil surgeon at Bakarganj, Eastern Bengal, has been granted one year's leave. Captain Godson, from Goalpara, is appointed to officiate as civil surgeon at Bakarganj. Captain McCoy, civil surgeon at Sylhet, has been granted 20 months' leave. Captain P. L. O'Neill has been appointed district medical and sanitary officer, Bellary, Madras. Captain G. P. T. Groube has been appointed to officiate as civil surgeon, Seoni District, and to the executive and medical charge of the District Jail. Captain A. S. Lisle, whose services have been placed temporarily at the disposal of the Burma Government, has been posted for duty at Inslin Central Jail. Lieutenant F. O'D. Fawcett, attached to the 23rd Cavalry, has been transferred for duty with the 59th Rifles.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st Home Counties Field Ambulance: Lieutenant Joseph Ward to be Captain (dated Feb. 1st, 1910).

For attachment to Units other than Medical Units.—Hugh Davies to be Lieutenant (dated Dec. 11th, 1909). Charles Percy Woodstock to be Lieutenant (dated Jan. 1st, 1910). William Robert Wilson to be Lieutenant (dated Jan. 10th, 1910).

Correspondence.

"Audi alteram partem."

SINGLE-HANDED ATTENDANCE AT DIFFICULT LABOURS.

To the Editor of THE LANCET.

SIR,—I have received the following letter dealing with a subject of such practical importance that I gladly avail myself of your permission to reply to it through THE LANCET.

1, Carcroft Villas, Carcroft, near Doncaster,
March 5th, 1910.

To the Master of the Rotunda Hospital.

SIR,—I am encouraged by the knowledge of your never-failing desire to be of service to the students of your hospital, past and present, to seek information on a subject very perplexing to your correspondent and of vital importance in obstetrical practice, as it brings under consideration the question of prevention of sepsis in maternity cases, and with this object in view I wish to ask what procedure you would recommend in a case where, *single-handed*, you were compelled to deliver a patient of a fœtus or placenta, and at the same time have your patient fully anæsthetised? I have been more than once confronted with this difficulty and must admit that I consider the fortunate results, if not providential, were either due to the non-virulence of the micro-organisms or the extraordinary resistance of the patient, for when one has to leave the operation to attend to the chloroform and return without delay to the necessary manipulations, the difficulty of avoiding septic contamination is obviously very great and necessarily a source of worry to the conscientious medical attendant. I should therefore feel honoured and instructed if you would kindly answer my inquiry either by letter or through THE LANCET, and thus benefit many more general practitioners and the maternal portion of the community. It could be dealt with from a practical standpoint and not illuminated with the flowery language and want of instruction so evident in text-books, all of which presuppose the G.P. to have about him all the facilities of a large maternity hospital. If you could suggest some means of keeping forceps sterile when boiled in the ordinary way but not for immediate use it would be useful, as not being of an ingenious turn, and not being possessed of a steam steriliser, I know no means of rendering a towel or other case sterile, and the means of sterilising instruments in the patient's house are not satisfactory. I had the pleasure of reading your paper in this week's LANCET—The Modern Treatment in Cases of Contracted Pelvis. I deem it instructive, but then I must admit it was the first time I had heard you speak of *high-up forceps*.

I shall esteem it a very great favour if you will kindly clear up my difficulties.

Yours truly,
C. SHEAHAN.

All practising obstetricians have been confronted with the difficulty of attending single-handed at a labour case, and to do so in an aseptic and efficient manner is a procedure calling for considerable forethought.

"Management of a case" to my mind comprises an intelligent supervision of all that concerns the welfare of the woman in labour and of her infant. In the absence of a nurse the accoucheur's duties will include: (1) preparation of the room; (2) personal attention to the patient; and (3) attention to the child.

Under the first head must be included attention to the fire; the collection and cleansing of basins and jugs; preparation of antiseptic lotions, douches, &c.; preparation of bed, diapers, &c. Under the second head is included disinfection of the patient, attention to the diet, to sleep, and to exercise, and to the bowel and bladder functions; palpation, auscultation, and perhaps vaginal examination; pressure on the fundus if necessary; the administration of chloroform; the support of the perineum; control of the uterus; expression and delivery of the afterbirth; examination of the perineum, and suture of the latter if required, and the final washing up and binding. Under the third head we include examination to ascertain whether the cord is round the neck, and if so, its prompt liberation; the cleansing of the child's eyes and mouth; the delivery of the shoulders; ligature and division of the cord; the possible resuscitation of the infant; the bath; dressing the cord, &c. This surely is a pretty formidable task to expect one person to carry out efficiently, and yet it is precisely the duty which has, by Act of Parliament, been relegated to midwives, many of whom, because of a deficient training, have not acquired the aseptic instinct.

The management of labour has been greatly simplified since the introduction of rubber gloves, and I suggest one plan at least which will with their aid enable us single-handed to cope with our difficulties. Preparation of the room, bed, vessels, antiseptics, administration of medicine, food, and enemas, and palpation and auscultation can all be undertaken with ungloved hands. When pressure signs appear the patient is best placed in the side position, with hips well out, and thighs flexed on the abdomen. To obtain such a position the personal help of the accoucheur is nearly always required. The anæsthetic can be administered by dropping chloroform on to a mask held by the patient to her face. When not in use the chloroform bottle should stand in a bowl of cold corrosive sublimate solution.

The time has now come to wash the hands in a very thorough manner and to draw a glove on the left one. This hand is now passed between the patient's legs and controls the head as it presses down on the perineum. All the manipulations involving contact with the vulval opening should be carried out by this hand. The right ungloved hand will have much necessary, but more or less soiling, work to perform; this work need not be particularly specified. During the delivery of the head it is an easy matter to make the elbow of the left arm follow down the fundus. During the delivery of the shoulders both hands will be found useful and can be employed in a perfectly safe manner. They will be required for tying and severing the cord, and for lifting the baby from the bed. The perineum should be washed and examined for tears, and these are best stitched immediately. To do this, a needle is held in a needle-holder by the ungloved hand, whilst the gloved one passing between the legs of the patient separates the vulval orifice and directs the needle's progress. The obstetrician now helps the patient to turn on to her back and uses the right arm exclusively for the purpose. The glove should be rapidly removed from the left hand, and whilst doing this it turns inside out and becomes a right-handed glove. It is dropped into a solution of antiseptic, or better still into a saucepan of boiling water to be disinfected. The hands are again to be rapidly washed and the glove applied, but this time to the right hand, the duty of the left is now to support the fundus and to express the placenta when the time comes to do so. The right receives the afterbirth and manipulates the membranes so that they may be detached in their entirety. The final washing up and the application of the scorched pad to the vulva is relegated to the gloved hand; the glove should be removed before the binder is applied.

Gloves cost under 3*s*. per pair, they stand repeated boiling, and when used with care, disinfected, dried, and powdered with baked French chalk after use, they will last intact for months. It is usually only necessary to employ one glove at a time, the second one can be used for emergencies. I consider it almost criminal folly to be unprovided with these necessary adjuncts, and a benefit to humanity would be conferred were the Central Midwives Board to compel their universal adoption amongst midwives. In the event of forceps being found necessary, both gloves should be requisitioned, but not until the patient has been anæsthetised whilst lying in the correct position for their employment, or it may be found more convenient to lock the forceps first. Before administering the anæsthetic the gloves should be removed and reapplied before extraction.

Before the introduction of steam sterilisers I was in the habit of boiling my linen roll instrument case, drying it in the oven, placing it on a clean towel, and ironing it. My forceps and other instruments were boiled in weak lysol solution, and laid without previous drying on to the linen case. Their great heat caused quick evaporation, and prevented any tendency to rust. This linen roll, which I still employ, resembles an opened envelope; the edges are folded over the instruments before being rolled up. If protected from touch contamination such a case will require sterilisation only at long intervals. Air contact may to a large extent be disregarded; I say to a large extent, for I am not one of those who hold that septic organisms cannot be deposited through the medium of air. They are, however, deposited in very small numbers and in such isolation that their presence may be discounted. Soiled instruments must be carried home in a separate case, and ungloved fingers must not be permitted to touch the inside of the case. As a further protection my roll has an outer waterproof covering, and this avoids its contamination.

Mr. Sheahan expresses surprise that I have in a recent paper dealing with contracted pelvis given a qualified approval of the application of high forceps. My view in respect to this question has never varied—namely, that an unfixed head is a contra-indication to forceps application, but that in spite of this contra-indication they sometimes succeed in delivering a living child and may therefore be

tentatively used provided all arrangements are made for rapid delivery by some enlarging operation in the event of their purpose not being rapidly attained.

I am, Sir, yours faithfully,

Rotunda Hospital, Dublin. E. HASTINGS TWEEDY.

LEGISLATION IN ANÆSTHETICS.

To the Editor of THE LANCET.

SIR,—In his letter which appeared in THE LANCET of March 26th last Dr. Blumfeld very properly draws the attention of the profession to the proposed amendment by the Council of the Royal College of Surgeons of England to the important legislative recommendations of the General Medical Council in regard to anæsthetics. As Dr. Blumfeld points out, the suggestion of the Council of the College that registered dental practitioners should be permitted to administer certain scheduled anæsthetics for operations other than those of dental surgery would, if carried into effect, bring about one of the very evils which the General Medical Council is endeavouring to remedy—viz., the assumption by those who have received only a partial medical and surgical training of responsibilities and duties which can only be discharged satisfactorily by those who have passed through the full medical and surgical curriculum. I must confess that I am at a loss to understand such a suggestion, and I am glad to observe in the minutes of the meeting of the Executive Committee of the General Medical Council held on Feb. 21st last (p. 25) that this committee was unable to agree to the proposed amendment by the Council of the College.

The following is the resolution passed by the Executive Committee on the occasion of a communication from the Lord President of the Privy Council submitting the amendment proposed by the Council of the College of Surgeons, the "words proposed to be omitted" referred to in the resolution being those used by the General Medical Council in the legislative recommendations they forwarded to the Lord President of the Privy Council restricting registered dentists to the use of certain scheduled anæsthetics in dental surgery:—

That the Lord President be informed that the words proposed to be omitted were inserted advisedly by the Council, and in the opinion of the Executive Committee it is desirable in the public interest that they should be retained. The Executive Committee would point out that cases may occur in which, during the course of medical or surgical operations, commenced under anæsthesia produced by nitrous oxide or other "specified" preparation, it is found necessary at a later stage to resort to more potent anæsthetics such as chloroform or ether. In such a case it might endanger the patient's safety, and the success of the operation, were the anæsthetist unqualified to administer the latter, as under the legislation proposed an anæsthetist possessed only of a dental qualification would be.

It is a matter for congratulation that the Executive Committee of the General Medical Council have so fully realised one of the main objections to the proposal made by the College of Surgeons in regard to the administration of anæsthetics by dental practitioners. With the other objections Dr. Blumfeld has adequately dealt, and I fully endorse his views. I would lay particular stress upon one of these objections—viz., that under the proposed amendment the risk of general anæsthesia in patients suffering from grave constitutional conditions would greatly be increased. I would point out that it would be distinctly contrary to public interests and to the general spirit of the proposed reforms to expect practitioners who are not in the habit of meeting and treating general medical and surgical conditions clinically to take upon themselves the responsibilities of anæsthesia in general surgery. The vast majority of patients requiring anæsthetics for dental operations are in good or fair health, and though personally I am still of opinion that medical men are the proper persons to administer *all* general anæsthetics to such patients, it must be admitted there is but little risk to life when the safer of these anæsthetics are administered by qualified dentists who are not themselves operating. But if the proposal of the Council of the Royal College of Surgeons were to take effect we should have dental practitioners administering their scheduled anæsthetics to patients of a class totally different from that which in the ordinary routine of their work they are accustomed to meet. As matters now stand, such patients almost invariably obtain the services of two medical men (except in conditions of extreme urgency) whenever a surgical operation has to be performed; and we should be opening the door to a new and unnecessary danger were our legislature to sanction the administration of general anæsthetics to such patients by those who have had little or no clinical experience to guide them. Moreover, *cæteris paribus*, the risk of anæsthesia is undoubtedly less in dental than in general surgical operations owing to the almost invariable preliminary insertion of the mouth-prop—a procedure which is largely instrumental in preventing obstructed breathing.

It is highly satisfactory that, with the one exception in regard to dentists, the Council of the College agrees with the proposals of the General Medical Council, and it is to be hoped that the report of the Departmental Committee, which will, I understand, soon be issued, will be equally favourable to legislation. Whilst many of us hoped that the General Medical Council in their proposals might have restricted the administration of all general anæsthetics to registered medical practitioners and the use of local (injected) anæsthetics to registered medical or to registered dental practitioners, there can be no doubt that their scheme to allow registered dentists to administer certain of the least toxic general anæsthetics in dental surgery is deprived of much, if not most, of its objections by the important reservation that, save in the most exceptional circumstances, the administration of the anæsthetic and the performance of the operation shall not be undertaken by the same individual. There can be no doubt, indeed, that the legislative recommendations of the General Medical Council deserve the unqualified support of the whole profession. They certainly meet the difficulties and requirements of the situation as well as they can be met and if, as I trust, they may shortly become law, a great public service will have been rendered.—I am, Sir, yours faithfully,

London, April 5th, 1910. FREDERIC HEWITT.

ACCIDENT CLAIMS AS AFFECTING THE MEDICAL PROFESSION.

To the Editor of THE LANCET.

SIR,—I think that most medical men who have had much experience of work in connexion with the Workmen's Compensation Act will agree with Mr. Albert Benthall's strictures on the conduct of a small number of medical men who are constantly in evidence in such cases. These gentlemen are well known to medical examiners for insurance offices, &c. (and, unfortunately, are well known to the workmen also), as prepared to back any claim, *bonâ fide* or otherwise, in court or out of court. Fortunately, for the credit of the profession to which they belong, they are few in numbers, but their power for harm is not to be measured by their numerical insignificance.

Another most important matter is the question of providing special treatment for and, consequently, obtaining a certain amount of control over certain accident cases. It has always seemed to me that the absolute lack of any practical control over the carrying out of the treatment of a case is not fair to the insurance company and the employer. I am afraid that I cannot agree with Mr. Benthall in considering that "the great majority of working-men are honest" when it comes to a question of compensation for injury. I have examined some hundreds of cases annually during the past eight years, and it is my experience that there are very few which are not exaggerated, to say the very least, in some way or another. I think it would be difficult to find any Act of Parliament that has had so demoralising an effect as the one in question. For this result I think the insurance companies themselves are somewhat to blame. What is it that makes an injured man try and drag out his case to the uttermost? Is it the prospect of half-pay—and possibly club money in addition—with nothing to do? I think not. I think it is the prospect of his case being settled by the payment of a lump sum. I firmly believe that this method of getting rid of a case is at the bottom of most of the malingering that goes on. And everything is in favour of the man who is playing this sort of game. Granted that he is genuinely injured, what control is there over him to see that he carries out his treatment? He is probably either a club patient or an out-patient at one of the hospitals, and in neither case can the treatment he can receive be considered satisfactory. In the first instance the most suitable treatment can often not be carried out in his home (even if the man would take the trouble to follow instructions), and in the second because in the bustle and over-work of a crowded

out-patient department he cannot receive the attention that he requires. If he is malingering he stands a good chance of avoiding detection from the same causes operating. It is in such cases (and they are legion) that some control over the patient is necessary. I do not, however, believe that a voluntary scheme would prove a success. The malingerer would naturally refuse to take advantage of it, as would also those who, if not actually malingering, are in no wise anxious to expedite their recovery. I believe that in Germany there is a scheme under which a man has to enter hospital (or place himself under control) after the lapse of a certain time after the injury. I fear there is no present prospect of any such scheme becoming practical in England, but I feel sure that some such method will have to be adopted in the near future.—I am, Sir, yours faithfully,

HENRY J. CARDALE, M.B., C.M. Edin.

Glengall-road, Poplar, E., April 5th, 1910.

THE MIDWIVES ACT AMENDMENT BILL.

To the Editor of THE LANCET.

SIR,—Will you allow me to call attention to a proposed grave injustice to thousands of poor women? At present when a woman in her hour of trial is attended by a midwife the midwife is required by statute to summon a doctor if any complication ensues. No provision is at present made for the payment of the doctor whom the State, not the patient, insists on summoning. This is an injustice to the doctor.

Now the Government proposes (in the Bill just introduced by Lord Wolverhampton) to require the board of guardians to pay the fee (as parochial relief to the woman and her husband). This is a grave injustice to these poor families. The woman and her husband are not paupers, they are not even destitute persons. Through the exercise of thrift they have made for themselves the normal provision for childbirth of their class—i.e., a midwife. The Government proposes to make them compulsorily into paupers (even if they subsequently repay the full amount it makes no difference in this respect); their homes will be visited by the relieving officer with his hated inquiries, often to the detriment (as any nurse or midwife will testify) of the woman's health; they will be liable to be proceeded against by the board of guardians if (as is intended by Clause 17, Sub-clause 2) the "relief" is given "on loan," and compelled to repay a charge which they have never incurred, but which the State in the public interest has chosen to require.

I cannot believe that the House of Lords will choose this moment to thrust thousands of poor women involuntarily into pauperism; or that the House of Commons will think of tolerating such an injustice. When the police call a doctor to attend to a patient in an emergency, the fee is paid out of the municipal funds, and the patient is not thereby made a pauper. The town councils of Manchester and Liverpool are already, with the knowledge and consent of the Local Government Board, following a similar course with regard to the doctors called in by the midwives; and this course is open to any other sanitary authority (under Section 133 of the Public Health Act). There is accordingly no need for the degrading and insulting Clause 17 of Lord Wolverhampton's Bill; and I hope that the Government will withdraw it. I am, Sir, yours faithfully,

BEATRICE WEBB.

Grosvenor-road, S.W., April, 1910. (Mrs. Sidney Webb.)

THE INDIVIDUAL COMMUNION CUP.

To the Editor of THE LANCET.

SIR,—I would like to ascertain, through the pages and readers of your esteemed journal, whether any cases of contagion have been traced to the use of the "common cup" at Communion table. We are trying to persuade our clerical missionaries to introduce the "individual cup" into the churches out here in China, and I shall be most grateful to anyone who can furnish me with authenticated data on this subject. I am, Sir, yours faithfully,

Peking, China, March 12th, 1910. J. J. MULLOWNEY.

*** The question has been much discussed in our columns, and we refer our correspondent in particular to the letters and articles which appeared in THE LANCET during the latter part of 1900. The measure of the risk depends, of course, upon the sort of community that is in question.—ED. L.

THE PUBLIC HEALTH AND THE PARIS FLOODS.

(FROM OUR SPECIAL SANITARY COMMISSIONER.)

(*Concluded from p. 756.*)

THE Parisians are congratulating themselves on the undoubted fact that never before in its history has Paris been so clean. In dealing with the sewers it has been shown that they were flushed by 30,000,000 to 40,000,000 cubic metres of water per day instead of conveying some 400,000 cubic metres of sewage. From culvert to the roof and under a pressure of 10 metres these sewers were scoured out with a thoroughness that no artificial measures could have effected. The insides of 14,000 houses have been scrubbed with disinfectants under municipal orders, and the dirt and rubbish removed from cellars to courtyards. The fear that the flood would cause an epidemic also engendered a wholesome fever for cleaning among individuals. People who had never before thought of looking into dark corners and recesses underneath staircases, awoke to the danger of such neglect. Old papers, broken furniture, discarded objects of every description in every phase of disgusting disintegration had been pushed into out-of-the-way corners or cellars, there to stay till the floods came and the disinfectors and sanitary and other authorities followed. Never before had these houses been inspected so frequently and by so many authorities. Under this pressure every householder or occupier, whether rich or poor, was seized with the one thought, the one desire—that of cleaning everything. At the Palace of the Elysée, where the President of the Republic resides, the desire for cleaning was made manifest. Passing through the porous subsoil, the waters of the Seine had invaded the Elysée cellars, and even here there was rubbish that had accumulated since the days of the *Coup d'État* or some earlier date. Built for the Comte d'Évreux in 1718, the palace became a gambling hell during the great revolution. It was afterwards inhabited by Napoleon I., then by the King of Holland, and later by his son, Louis Napoleon, when he plotted the destruction of the Republic in 1851. The amount of rubbish stored in the cellars of the vast and historical edifice was enormous, and the chief of the department for the removal of refuse assured me that the clearing of the Elysée was the hardest piece of work the flood had occasioned. No less than ten extra carts, with a capacity of six cubic metres each, had to be employed and much labour and time spent to cart away the many tons of rubbish that had accumulated in the basement of the Elysée Palace.

The scavenging department in Paris is under the control of M. Boreux, Inspecteur-Général des Ponts et Chaussées, who is inspector of what are familiarly called the *boîtes à Pourbelle* (dustbins). Formerly all the household refuse was piled up in the streets at night, but M. Pourbelle, when Prefect of the Seine, compelled each householder to provide portable metallic boxes in which rubbish could be placed in the daytime, and these boxes were to be put out in the street at night ready to be emptied into the collecting carts that go round in the early morning. When once this system had been instituted it became illegal to pile up rubbish on the causeway or road. The fact that all household refuse had to be put in a box certainly helped to keep the streets clean, and it was much easier to empty boxes into the carts than to shovel up the material from the ground. But even when assisted by this sensible system, the daily cleaning of the streets of Paris is a very laborious and extensive task. It has also been made the subject of any number of experiments and speculations leading to the granting of concessions to various companies. As these, for the most part, proved failures, further complications arose, and the municipality had to take over the work which private companies were not able to carry out with sufficient advantage to themselves. Thus actually the domestic refuse from I., VIII., XIII., and XVI. arrondissements belongs to contractors who are owners of works outside the town where the refuse is pulverised and converted into manure. But the carts in which the refuse is conveyed belong to the municipality. On the other hand, the horses belong to, and are fed by, the contractors, though, and as a final complication, they are lodged in municipal stables!

As so many of the outlying districts were flooded it

naturally occurred to me that at the works where the refuse is converted into manure there would be large accumulations of rubbish which the flood would carry away and spread far and wide. There might be some danger in this. On inquiry, however, I found that my apprehensions were 15 years out of date. Formerly all the refuse of Paris was handed over to private contractors, and there was a danger that large quantities might occasionally be held back till the market became more favourable for their sale. Now only the refuse of four out of the 20 arrondissements is thus given over; and, according to the regulations in force, it must be all utilised within 24 hours. The populations in the neighbourhoods of the manure works insisted on these regulations and ensured thereby that no nuisance to them should arise. The Brussels Sugar Convention has had a great share in saving Paris from the danger of the dissemination of manure by the floods, though certainly no one concerned in the treaty foresaw that such a result would ensue. It appears, however, that the pulverised refuse of Paris served mainly to manure the fields where beetroot used in the making of sugar was grown. Now that sugar in France is so much cheaper less beetroot is cultivated, and therefore the pulverising of Paris refuse to make manure for beetroots has been to a large extent abandoned. As a further result a greater proportion is disposed of in destructors, which, if expensive, is certainly the most wholesome process. Consequently, the fact that some of the works where these waste products are utilised were flooded did not cause the scattering about of large accumulations of rubbish. But it was a very serious inconvenience not to be able to send the fresh rubbish to these works as it was collected.

Not only were the means for the disposal of refuse reduced, but the wholesale cleaning, especially of the cellars, caused an immense increase in the output of rubbish. This was divided into three categories: (1) kitchen or food refuse; (2) mud, mineral matter, dust, and the scrapings from cellar walls and floors; (3) old and soiled bedding, furniture, wooden or cardboard boxes or cases, and all manner of things that can be burnt. The first category is the contents of the Pourbelle boxes, and in consequence of the difficulties of communication some of it had to be emptied into the Seine from the Tolbiac bridge to the east of Paris and the rest at the Point-du-Jour on the west side. It certainly was deplorable that any refuse had to be disposed of in this way, especially that some of it had to be shot into the eastern end, but the necessity for such action did not continue for more than a few days, just when the floods were at their worst and the volume of water was enough to dilute anything. The second category, "hard core" is the English technical name, was too voluminous to be put in the Pourbelle boxes. It was mixed with disinfectants, carted away, and emptied into sand-holes and other hollow places that needed filling up. The third category, bedding, furniture, straw, old papers, wood, was first piled up in the streets and then taken to some open space at the fortifications, when petroleum was poured over it and fired. To remove all the mud from the streets, the "hard core," and the "soft core" or garbage, &c., 600 carts of five to six cubic metres capacity are usually employed per day in Paris. But 100 supplementary carts had to be engaged to remove the extraordinary amount of rubbish brought out of the inundated ground floors and cellars. The last figures I was able to obtain show that in 1907 the refuse from Paris amounted to 1,369,997 cubic metres. It will be interesting to know how much this figure has been exceeded this year as a consequence of the floods. The total cost of removing and treating or disposing of this refuse in 1907 amounted to 3,781,893 francs, or 2·75 francs per cubic metre (in round figures and in English money, £151,000, or 2*s.* 2½*d.* per cubic metre), and the population for which this expenditure was necessary was set down at 2,714,000.

The effect of the flood on the working of the great public health services has not proved disastrous; they stood the strain well, and the result has been a general cleansing of the inundated quarters. But have the inhabitants themselves escaped so easily? Fortunately, there are not many inhabitants on the ground floor. In most houses the only persons who sleep on a level with the street are the *concierge* and his family. The rest of the ground floor is generally let out as shops. Without the extra trouble of floods, the house porters were already an unhealthy class, because they are generally lodged in dark, badly ventilated, and small apartments near the main entrance, and giving on to the diminutive backyards of the lofty Paris houses. That these noisome abodes have now been thoroughly cleaned out, and the old furniture and rubbish burnt, will certainly be an advantage. On the other hand, and in spite of fires, these quarters are likely to be damp, especially when the water had remained in the cellar below for some weeks. Here, then, are unwholesome conditions, and it is very probable that the *concierges* as a class will in time be found to have suffered in health. As for the extreme poor living in slums, the floods have been a blessing to them in disguise. So much was this the case that many poor people, especially those belonging to the professional mendicant class, pretended that they were victims, though they did not live anywhere near the inundated districts. The assistance given was so plentiful and easily accorded that many obtained relief who were in no wise entitled to it. Schools, old seminaries, and other places were converted into dormitories, and here the slum-dweller whose house had been invaded by water enjoyed the rare luxury of a bath, a clean bed, and good meals. Many of them thus obtained free quarters for ten or more days, and when finally they went back to their homes in the slums these had been cleaned beyond recognition. The extreme poor, therefore, will have benefited by the floods. The wealthy have the means of taking care of themselves, and, most fortunately, there is comparatively but a small proportion of the intermediate classes in the parts of Paris that were inundated.

It is in the districts outside Paris that the greatest losses and suffering have been experienced. Here most of the houses are small and lightly built. Some of these dwellings were entirely swept away, others were rendered totally uninhabitable. The small city clerk who for years has saved a portion of his meagre salary to buy a little cottage in the country outside Paris has seen all his economies carried away by the flood. Many of this class are just too well off to be relieved by charity, but not well enough off to be able to regard their losses with indifference. Many have returned to inhabit their homes in spite of their dilapidated and damp condition. The little tradesmen have had their stock-in-trade destroyed, and over wide stretches of well-populated semi-rural suburbs the greatest distress prevails; not pauper or indigent distress, but severe financial strain among comparatively well-to-do sections of the community.

Needless to say this seriously affects the position of the medical practitioners established in the inundated country. The Medical Union of the Department of the Seine at once met to discuss what could be done. A resolution was passed that all the funds in the hands of the union should be placed temporarily at the disposal of the medical practitioners who were injured by the floods. It was with sore hearts that this vote was given, for it had required much patient labour to collect, little by little, a reserve fund for the union, and such moneys are much needed for legal expenses or strike allowances when a struggle occurs. However, in the face of so widespread a disaster no sacrifice was too great, and therefore the Medical Union offered all it possessed. Circulars were printed to that effect and sent out to 4000 medical practitioners. A totally unexpected result ensued. A number of medical men, many of them not even members of the union, were so struck by this chivalrous action that they sent donations to the Medical Union, so as to help in the relief of practitioners who had suffered from the floods. On the other hand, these victims, knowing how necessary it was that the Medical Union should keep its funds for the defence of the economic interests of the profession, made no applications to the union for relief. One member only asked to be exempted from the payment of his subscription for the time being. Some wrote relating how all their furniture had been destroyed and nearly all their patients ruined. They therefore did not think the latter would be able to pay the medical fees they owed. Yet these correspondents did not ask for anything. Some described the difficulties of other practitioners, thus pointing out where help was needed, but never asked for anything for themselves. One practitioner explained that he had eight victims lodged in his house, that his gas- and water-supply were stopped, and his closets were not in working order. Several practitioners wrote not to make demands for help, but to offer to take charge of the children of other medical men less fortunate than themselves. It may be said that the work of

relief by rights appertained to the Association Générale de France, for it is a purely benefit society, and has a very large membership; but like these old-established institutions it is slow to move. It has its routine system of assisting the widows of medical men and various cases of exceptional distress among members of the profession, but it is too ponderous a body to be able to move in response to a sudden, unexpected emergency. The fighting unions alone had the youth and energy necessary to rise to the occasion. The floods came just as the annual bills had been sent in by most of the practitioners, and the greater part of the work they did last year has not been paid for, and some of it never will be. It will add to the distress in some of these outlying districts that several practitioners have determined to leave, but they cannot afford to remain in a place where all the likely clients have been ruined.

I make no attempt to describe the varying conditions in the suburbs affected, but the district within that loop of the Marne which encircles the commune of St. Maur was the subject of interesting treatment. Here the mayor at once divided his commune into 16 sub-districts, and appointed a committee for each of these divisions consisting of at least one medical man, one architect, and one municipal councillor. The mission of these committee men was to see that the instructions issued by the Paris police were duly carried out. They therefore had to visit every house and report if it had been disinfected, and see if it was properly disinfected. Only after this had been done did they give the necessary written sanction allowing the owners or occupiers to re-inhabit the houses examined. Disinfectants were provided gratuitously at the town hall, and chemists came from Paris to help. Practically no resistance was offered, though at least a quarter of the houses were flooded. The loop of the river Marne is very pretty at this point, and the inhabitants seek to live near to the water's edge. Altogether there are seven miles of river front, and naturally the villas close to the water were flooded. There are no extreme poor here, and much of the furniture was too good to be destroyed. This was particularly the case in regard to the wool and horsehair or spring mattresses. Fortunately, behind the town hall there happened to be an unoccupied factory, and here 2800 mattresses were disinfected. The owners had to throw buckets of water upon the mattresses, and scrub and wash the outside. Then a municipal service of carts came to fetch the mattresses and placed them in one of the rooms of the empty factory. Here there were large *brasseros*, like those which are lighted on the terraces of cafés so that customers may sit out in the open air during cold winter months. When the mattresses were dried they were taken to another compartment which had been rendered airtight and 30 grammes of formalin per cubic metre of space were evaporated by heat. The mattresses were first partially unsewed so as to facilitate the penetration of the gas. After being thus disinfected the mattresses were carried to a third room, where as many draughts as possible were created to free them from odour. It was undoubtedly an excellent precaution to disinfect on so extensive a scale, for the whole district drains into cesspits. The older cesspits are not watertight, and they caused no visible nuisance, but the contents of the watertight cesspits came out for the most part in the flooded gardens. Some of the one-storey houses had the water up to their roofs, others had four and five feet deep of water in the sitting-rooms. The fugitives went to the schools, which were quickly converted into dormitories; the greater part of the children were sent some distance away into the country, where they were generally received as guests by people who were glad of an opportunity to render some service.

It will be seen from the above that the mayor of St. Maur acted with commendable energy and made good use of the local facilities available. But the Government could not be certain that this would be the case in the 32 communes round and about Paris which had suffered from the floods. Therefore special decrees were issued from Jan. 28th to Feb. 16th by the sanitary departments of the Ministry of the Interior and of the Prefecture of Police bringing the authority of the Central Government to bear upon the local municipal or communal administration. Not only were the mayors told what should be done, but special inspectors were appointed to watch over the local authorities and see that the instructions given by the Government and the Prefecture of Police were duly carried out. Thus, it will be seen, very little was left to chance. This, however, will not, and could not, prevent the destruction wrought by the waters, nor the poverty, the mental strain, and anxiety that such a disaster must occasion. The danger that a widespread epidemic would ensue has been met and, there is every reason to anticipate, successfully warded off. But there may be an increased sick-rate and death-rate from ordinary causes due to the weakening, the depressing effects of the trouble which has befallen so many people. The vital statistics of the inundated districts during the next few years will be of special interest, but with the early advent of the spring and summer sun to complete the process of drying the houses we must hope that but little further harm will accrue.

VARICOCELE AND THE PUBLIC SERVICES.

(BY A SPECIAL CORRESPONDENT.)

IN a leading article in THE LANCET of March 26th (pp. 869–870) a plea was put forward that "varicocele should not of itself be a cause of rejection of candidates for the Services who are otherwise suitable, and candidates should never be advised or required to submit themselves to operation for its cure." With regard to the first part of this plea, it may not be generally known that quite a number of recruits are rejected annually for the army on first inspection as suffering from varicocele. The accompanying table,

Year.	Total recruits inspected.	Rejections for varicocele.		Rejections from varicocele within 3 months of enlistment.	
		Actuals.	Ratios per 1000.	Actuals.	Ratios per 1000.
1900	84,402	946	11·21	20	0·24
1901	76,750	1066	13·89	43	0·56
1902	87,609	1103	12·59	84	0·96
1903	69,553	908	13·06	26	0·37
1904	70,346	1158	16·46	21	0·30
1905	66,703	1117	16·75	26	0·39
1906	62,371	797	12·78	7	0·11
1907	59,393	678	11·42	5	0·08
1908	61,278	761	12·42	7	0·11
1909	Figures not yet available.				

compiled from the official returns of the last ten years issued to Parliament by the Secretary of State for War, shows very plainly the importance of the questions which have been raised. For instance, in the year 1904 out of 70,346 recruits medically examined for the British army no less than 1158 were rejected on first inspection as unfit from varicocele, giving a ratio per 1000 for this condition alone of 16·46. In the ten years period between 1897 and 1906 of 712,309 recruits medically examined, 9524, or a ratio per 1000 of 13·37, were rejected on first inspection, and 257, or a ratio of 0·36 per 1000, were rejected within three months of enlistment as medically unfit for the service as suffering from varicocele of sufficient degree to interfere materially with their proper performance of military duty. In 1906 the army medical authorities, apparently realising that the importance of varicocele had been somewhat over-estimated in the past, began to take a more lenient view of its presence. A definition of what they termed a "standard" for varicocele was formulated. In 1907, as a result of this standard, the rejections for the disability in otherwise suitable recruits became reduced to 11·42 per 1000 of men inspected, and at the same time the ratio of discharges from the same cause within three months of enlistment fell to 0·08 per 1000. These facts seem to prove that the importance of the disability was formerly over-estimated. In 1908 there was also a slight diminution in the number of rejections as compared with those that occurred in 1906; the figures for 1909 are not at present available.

The admission of soldiers with varicocele to the ranks of the army has, however, real difficulties. No defect is more useful to an unwilling soldier who wishes to evade his duty, especially a "fatigue" or a "route march," than a varicocele. He has only to report sick and complain of pain in the region affected and be sent before a military medical officer, who cannot state definitely that the

pain complained of does not exist, and must of necessity excuse the man performing the work allotted to him, as otherwise an injustice may be inflicted. The mere size of a varicocele is very little guide as to the probability of the pain being really there. Again, instances still occasionally occur in recruits in which the men plead the presence of a varicocele as rendering them unable to carry out their drills and preliminary training gymnastics, &c., and refuse remedial operation. If such duties are excused or modified these men when they become trained soldiers fall back on this their old excuse and continually ask to be excused fatigues, and if so excused an injustice is done to their comrades by increasing the proportion of the harder duties of the latter. For these reasons it seems worth considering, if recruits are to be passed into the Army suffering from varicocele, whether it would not be well to stipulate for their consent at a later date to operative treatment should it become necessary. This could only be done when accepting recruits, and the fact of their agreeing to it would prevent malingering. It may be noted in passing that there is a widespread belief amongst the classes of the population from which recruits for the army are drawn that even a small varicocele produces impotence, and so a demand for operative treatment has been prominent in young men about to enlist on this account and not because the condition causes any pain.

Coming next to consider the question of the prevalence of varicocele amongst serving soldiers the following statistics have been compiled from the official blue-books. Adding together the average strengths of the European British troops of the regular army serving in all parts of the world, we find the army in 1907 consisted of 225,266 men; of these, 118,429 were admitted to hospital during the year for treatment, and of the latter 2635 were finally invalided from the service. Of the admissions to hospital 214 were cases of varicocele, and of these but 2 were finally discharged from the army as unfit for service. The corresponding figures for 1908 show that of an average strength of 223,774 European British troops of the Regular Army 121,388 were admitted to hospital; of these, 2310 were eventually invalided, and of those admitted to hospital 311 were treated for varicocele, of which 5 were finally discharged from the army as medically unfit. In 1908 out of 2797 operations carried out at all stations excluding India, 178 were operations for the relief of varicocele. In India for the same year 38 cases of varicocele were operated on. As the effects of climate have been stated to favour the production of varicocele it may be of interest to quote the proportionate occurrence by commands. In 1907, of the 214 cases of varicocele above noted, 139 occurred in the United Kingdom (average strength 118,521), of which 2 cases were finally invalided. Mediterranean Command, 10 cases out of an average strength of 15,611; South Africa, 8 cases (average strength, 15,474); India, 50 cases (average strength, 69,332). Other commands, 7 cases (average strength, 6328). In 1908 corresponding figures for the United Kingdom show 192 cases of varicocele, of which 5 were finally discharged as unfit for army service out of an average strength of 118,474; Mediterranean command 18 cases (average strength, 15,548); South Africa, 7 cases (average strength, 14,075); India, 85 cases (average strength, 68,522); and other commands 9 cases (average strength, 7155). From consideration of these figures it appears that varicocele when it develops in serving soldiers causes but very little wastage, and if the crux of malingering be got over by making it understood that those who suffer from their varicoceles will have to be relieved by operation, there appears no valid reason why candidates for the ranks should *per se* be rejected for varicocele alone. In no case, however, where the condition is associated with varicose veins of the legs or piles should it be lightly looked upon.

BRISTOL AND THE WESTERN COUNTIES.

(FROM OUR OWN CORRESPONDENTS.)

University of Bristol: the Coat of Arms.

A SKETCH of the design which has been prepared for the University coat of arms has been published. It combines the ship and castle of the City of Bristol with the arms of Colston, Wills, and Fry. The heraldic description is as follows:—"Argent on a Cross quadrant Gules, a representation of the Arms of the City of Bristol (with the consent of the Lord Mayor, Aldermen, and Citizens), between impale a Sun in splendour and an Open Book proper leaved and clasped Or, and inscribed with the words 'Nisi Quia Dominus,' and in fesse to the dexter a Dolphin embowed, and to the sinister a Horse courant, both of the third." Beneath the shield, upon a scroll, is the motto "Vim promovet insitam."

Tropical Medicine.

The University of Bristol has appointed Dr. A. J. M. Bentley to deliver a series of 12 lectures on tropical diseases in the buildings of the Faculty of Medicine for senior students and qualified practitioners. In many respects Bristol would be a good centre for the establishment of a tropical school, and possibly the response to the present step may be of such a nature as to warrant further progress.

Gloucestershire Royal Infirmary and Eye Institution.

The annual meeting of the subscribers to the Gloucestershire Royal Infirmary and Eye Institution was held on March 31st under the presidency of Colonel Curtis Hayward. The medical report showed that during 1909 the in-patients numbered 1591, and 9051 out-patients were treated, both of these numbers being in excess of any previous record. The financial statement showed the income amounted to £7024, the expenditure was £7744, and the deficit on the year's working was £720. The chairman stated that with the object of increasing their income a league had been formed in order to bring the claims of the charity before the public.

Somerset County Education Committee and the Eyesight of School Children.

At the last meeting of the Somerset education committee it was decided, owing to the large number of children whose eyes had to be examined, to supplement the work of the ophthalmic school medical officer (Dr. J. H. Bendle) by the appointment for three months of a qualified medical assistant. The salary will be £100, in addition to travelling and out-of-pocket expenses.

Didworthy Sanatorium, Devonshire.

The annual meeting of the subscribers to this sanatorium was held last week under the presidency of Dr. R. Hogarth Clay. The medical report stated that during 1909 133 patients had been treated. 102 patients were discharged during the year; of this number 50 per cent. were "much improved," and 21 per cent. "very much improved." The sanatorium has 35 beds, and the cost of three months' treatment has now been fixed at £18. Several beds are maintained by local authorities at a cost of £70 per annum. The committee urges the importance of sending incipient cases of pulmonary tuberculosis, and states that during 1909 only 17 cases were admitted in the earlier stage. The report states that the scheme of receiving certain patients for one month for educational treatment has been continued.

Royal Cornwall Infirmary, Truro.

The male patients of the Royal Cornwall Infirmary have a convalescent home provided for them at Perranporth but the female patients have none. The want of a convalescent home for the women has been much felt, and Mr. T. L. Dorrington has promised £1500 for the erection of a suitable building. The committee of the infirmary thinks that the home could be furnished for about £200, and that the total annual expenditure would be about £200. It has been decided to call a meeting shortly to consider the generous offer of Mr. Dorrington.

Proposed University Settlement.

A committee has been formed, representing every faculty and every type of University member, to promote the formation of a university settlement. In a circular note the committee states that the aims of such a settlement would be, first, to promote the general welfare of the neighbourhood in which it is situated; and, secondly, to provide a centre for the systematic study of social and industrial conditions. The committee is of opinion that the settlement should include a residence for women under a warden, with library, and lecture- and club-rooms for both men and women workers. The increasing importance of training experts in social work is alluded to and the sympathy of students is asked for. The initial outlay would be about £1000 and the annual cost of maintenance about £300. No appeal has been made as yet, but £220 have been promised towards the initial outlay, as well as some annual subscriptions.

April 5th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Liverpool's Decreasing Death-rate: Medical Inspection of School Children.

THE deaths registered in Liverpool during the week ending March 26th numbered 264, equivalent to an annual mortality of 17·8 per 1000. At the corresponding period of last year the deaths numbered 374, representing an annual mortality of 25·5 per 1000. The chairman of the health committee at the last weekly meeting remarked that the returns for the first quarter of this year were now almost completed, and they constituted the lowest quarterly death-rate on record for the city. The medical officer of health, Dr. E. W. Hope, replying to the query whether the medical inspection of school children had any influence on the death-rate, said that it was a very valuable help. Everything of that kind contributed to the health of the city.

Lancashire Inebriates.

The quarterly meeting of the Lancashire Inebriates Acts Board was held at Preston on March 23rd. The chairman said the fact that 60 per cent. of the women still sent to the reformatory were mentally defective demonstrated the hopelessness of expecting the three years' detention to effect a cure. Reform in such cases was practically an impossibility, and this should be taken into consideration by those critics who delighted in advertising the apparent failure of the system. All that they could do was to ensure that during the term of detention, at any rate, these unfortunate women should be looked after, provided with healthy and useful employment, and prevented from being a source of disorder and social contamination to the rest of the community. The net proceeds of the industrial occupations of the inmates were £1054, and this amount was almost sufficient to pay for the cost of their food, which amounted to £1076; while in spite of having reduced the charge for maintenance to Lancashire committing authorities to 5*s.* 3*d.* per week per patient, there was a larger balance in hand at the end of the year than at the beginning.

The West Derby Guardians and Medical Appointments.

At a meeting of the West Derby board of guardians held on March 23rd a motion was proposed to the effect "that in future no applicant for an appointment under the board who was a member of the board, or who had been a member of the board within a period of six months, shall be eligible." The proposer of the motion said that at the present time there were eight medical men in the service of the union who had been guardians, and he thought that such appointments were looked upon with disfavour by the outside public. There were now no medical men on the board who were likely to apply for a position under the board, so that was an opportune time to bring forward such a proposition, which he did not think anyone could object to. The motion was duly seconded, and, after discussion, was carried unanimously. It is only fair to say that no reflection rests upon those gentlemen who had taken advantage of the present state of the law on the point, all of whom are carying out their duties in the most satisfactory manner.

April 5th.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Queen's University of Belfast.

THE first meeting of Convocation is to be held on April 16th, and in the notice issued to convene this meeting the secretary of the University gives extracts from the statutes to the effect, among other matters, that "at an ordinary meeting Convocation may discuss and pronounce an opinion on any matter whatsoever relating to the University." The agenda for the meeting are: (1) the election of a chairman and deputy chairman; (2) drafting of standing orders to regulate procedure; and (3) any other business. A most important circular has been issued to the graduates from a very influential body of graduates in arts, medicine, engineering, and law, who, as they say, "met to consider the present situation," and who append their names, with the Right Hon. Thomas Sinclair, M.A., as chairman, and Mr. J. W. Storey, B.A., as honorary secretary, urging that it is of vital importance that every graduate who has not already done so should without delay send forward his name for enrolment as a member of Convocation. In this circular it is pointed out that in four years from next November, Convocation will elect eight members on the Senate, and that, in the event of a vacancy in the chancellorship, it elects the new Chancellor. It is clear that the members of Convocation are determined to exert a very important influence on the life and administration of the University, and it is of the greatest importance that a man of "light and leading" should be elected chairman. It is hoped that matters will be so arranged that there will not be that friction between Convocation and the University of Belfast as occurred in the case of the late Royal University of Ireland, and it may need the most careful generalship on both sides and a good deal of give and take to prevent this occurring.

Nursing in the Belfast Workhouse.

To the great credit of the Belfast board of guardians it has substituted paid for pauper nursing, so that now the Belfast workhouse infirmary forms a great school for the training of nurses, but the expenses in salary and maintenance have become so formidable that the guardians have been discussing the desirability of such changes as would effect a considerable economy without prejudicing efficiency. The new system of nursing began 26 years ago. In 1899 the staff consisted of 94 nurses and probationers, and the annual cost amounted to £3357. There were also 17 paid attendants, costing £835, the total cost being £4192. There were at the same time 224 pauper attendants in the infirmary and 32 in the fever hospital. In 1903 the guardians wisely decided to dispense with the services of the pauper assistants in the infirmary, and the number of nurses was increased to 137, and in 1908 (owing to the nursing staff at the Abbey being increased to 26) to 185; and when the new Dufferin Hospital for Children was opened in 1909 the number of nurses was again augmented to 193, and the cost increased to £6969. At present there is one nurse to about ten patients in the infirmary, and one to less than five patients in the hospital. More thorough classification of the patients has taken place, new departments have been added, but it is difficult to see how any reduction in the expenditure for nursing can be made unless to the distinct disadvantage of the patients.

Health of Belfast.

At a meeting of the city corporation held on April 1st it was reported that between Feb. 20th and March 19th there were 118 cases of infectious disease notified—viz., 8 cases of enteric fever, 59 of scarlet fever, 2 of simple continued fever, 1 of puerperal fever, 17 of diphtheria, 1 of membranous croup, and 30 of erysipelas. There have also been notified 110 cases of pulmonary tuberculosis. The average death-rate from all causes was 21·0, 2·2 from zymotic diseases, and 7·5 from chest affections. The number of cases of infectious disease notified is greater than in the previous month or in the corresponding period of 1909, numbering 118, as compared with 88 and 73 respectively. The increase (as compared with the preceding month) applies to all notifiable diseases except puerperal fever, and is most marked in the case of diphtheria (17 as compared with 5), enteric fever (8 as compared with 4), and erysipelas (30 as compared with 21). There is a slight increase in the number of cases of scarlet fever, the number notified being 59, as against 54 in the preceding month. There is also an increase in the number of notified cases of tuberculosis of the lung, the number being 110, as compared with 79 in the previous month. 49 deaths were registered from whooping-cough, as compared with 10 in the same period of 1909. The high zymotic death-rate was due to the prevalence of measles and whooping-cough.

The Belfast Hospital for Sick Children.

A new convalescent home, in connexion with this hospital, was opened on April 2nd at Carrickfergus in a most pleasantly situated district in the neighbourhood of Belfast. Already eight beds have been provided, and it is hoped that funds will be forthcoming to provide more.

Beri-beri in Belfast.

On the night of April 1st a ship arrived in Belfast Lough from Rangoon with more than half the crew of 16 hands

prostrated with beri-beri. Even those still nominally fit for duty were so weak that they were unable to stand upright to haul on the ropes. The disease showed itself weeks ago, but the attack in most cases was so mild that the sailors were able to stand to their watches. Nine of the sufferers have been conveyed to the Union Hospital for treatment, but one man died shortly after the ship arrived in the Lough. The crew are all Danes or Norwegians, most of them being men in the early "twenties." The ship has been thoroughly disinfected.

Ventilation of Sewers in Belfast.

The medical officer of health and the executive sanitary officer have, as requested by the public health committee of Belfast, reported jointly on the question of the ventilation of sewers, and the use is recommended of tall shafts, not less than 9 inches in diameter, combined with surface ventilators, suitably placed, as the best method of ventilating Belfast sewers. It is suggested that these should be provided at the time of the laying of the sewers, and that all old and defective sewers should be re-modelled and air-shafts provided where required; sewers with steep gradients should have air-flaps provided so as to regulate the position in which the sewer air should be discharged. Reports from Professor St. C. Symmers and Dr. W. J. Wilson (lecturer on hygiene) are also appended. Dr. Symmers said that he had suspended agar plates for five hours in ventilators in certain localities named, and from all certain bacteria were obtained, being mostly cocci of the staphylococcus albus variety, and also a few colonies of the colon bacilli, as well as moulds and a large number of germs of the subtilis class. These bacteria, Professor Symmers reported, are not pathogenic to any well-known extent, but the mere fact that bacteria are rising in the exhalations from these ventilators is important as indicating a possible source of disease, for it is evident that if harmless germs can thus escape from the sewers disease germs when present may also pass into the air of the streets. This question of ventilation of sewers is interesting, as when the matter was brought before the Belfast Health Commission it seemed as if scientific medical opinion regarded sewer-gas of little importance as a carrier of disease germs.

April 5th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The French Congress of Medicine.

THE Eleventh French Congress of Medicine will be held at the Paris Faculty of Medicine on Oct. 13th, 14th, and 15th next. The officers of the congress are: Professor Landouzy, president; Professor Balzer and Professor Troisier, vice-presidents; M. Marcel Labbé, general secretary; M. Laignel-Lavastine, assistant general secretary; and M. Masson, treasurer. The following subjects, suggested by the previous congress, will be brought before the meeting by selected speakers: bradycardia, the treatment of symptomatic epilepsy, and the pathological relations of the liver and spleen. The following questions will be placed on the programme for discussion: mishaps in serum treatment, acute cerebro-spinal meningitis, tuberculin treatment, and diseases of the pancreas.

Impure Air and Putrid Emanations.

At a meeting of the Academy of Sciences held on March 14th M. Laveran presented for M. Trillat and M. Sauton of the Pasteur Institute a memoir showing that atmospheric air, when contaminated by the ordinary emanations of putrefaction, thereby acquired properties favourable to the existence of such pathogenic germs as might be suspended in it. M. Trillat and M. Sauton proved this experimentally by exposing bacilli of diphtheria, of typhoid fever, and of plague to the action of ordinary air containing gaseous emanations derived from putrid animal or vegetable matter. It was found that in certain cases not only was the life of the microbes prolonged, but there was a renewal of the vitality of some which had previously undergone attenuation to such a degree that they were no longer capable of growing in ordinary culture bouillon. M. Trillat and M. Sauton considered that these phenomena, manifested in the presence of putrid emanations, were in accordance with the general law that antiseptics when in small quantity had an intensifying action. From the hygienic point of view this idea is worthy of record, for it shows that respirable air may by the presence of gases of putrefaction be rendered favourable to the vitality of infective germs.

Leave of Absence for School Teachers before and after Childbirth.

On March 18th a law was passed granting to female school teachers about to become mothers a special leave of absence of two months with full treatment, one half of the leave to be taken before the birth and the other half after it. This period shall not include sick-leave. The teachers shall not return to duty until they have been medically examined and certified to be fit for work without danger to their health, and if a prolongation of the leave is necessary for this purpose it shall be granted.

"L'Agrégation de Médecine."

March 23rd was the last day on which medical men could enter themselves as candidates for the *concours de l'agrégation* to be held on May 23rd. An interval of 18 months will then have elapsed since the last competition of this kind, which took place in December, 1908. It remains to be seen if the disorderly scenes of that period will be repeated. On the present occasion there are only about 100 candidates. It is known that the majority of the great medical societies look unfavourably both on the forthcoming competition and also in a general way on the system of *agrégation*, but, on the other hand, the Société de l'Internat has by 103 votes against 19 declared itself opposed to the suppression of the *agrégation* and its replacement by the system of *privat-docenten*. The Medical Students' Union, which in 1908 supported the opponents of the *concours de l'agrégation*, seems now to take no great interest in the controversy.

The Congress of Physiotherapy.

THE LANCET in its last number announced the opening of the Congress of Physiotherapy. Its sittings lasted throughout the week from March 29th to April 2nd. There was a good number of foreign visitors to the congress. The great success of the congress was the exhibition which had been organised in an admirable manner by Dr. Albert-Weil in the Faculty of Medicine, who succeeded in making it thoroughly representative of all the subjects that came within the range of the congress. Indeed, one cannot help regretting that such an admirable exhibition is destined to be dispersed after such a short time of existence. There were on view a series of exhibits organised by the climatic stations and watering-places, and exhibits of electrical apparatus. The radiological section included a very fine historical collection which deserved examination piece by piece. The Association of Antituberculosis organisations showed a model of the Bligny Sanatorium and wall pictures representing the sanatoriums of Champrosay, Hyères, and charts illustrating the Association for Preserving Children against Tuberculosis, and the work of the Siegfried-Robin Antituberculosis Dispensary. The social festivities included a gala performance of "Aida" at the Opera, and a dinner at the Elysée on April 2nd.

The Lannelongue Medal.

Professor Lannelongue has just informed the Paris Surgical Society by letter that he has founded a prize consisting of a gold medal to be awarded every five years with an endowment of 5000 francs. The medal will be open to surgeons of all nationalities who shall have made during the preceding ten years the most important surgical discovery or the most useful investigations in the science and art of surgery. The medal, however, is not to be given twice running to men of the same nationality. M. Lannelongue expresses the formal wish that the awards shall be absolutely independent of nationality, and given solely upon the merits of the selected competitor. Amongst the members of the committee charged with its award will be men of ten selected nationalities, two at the most from each. The medal will be awarded to the candidate who shall obtain more than half of the total number of votes, or failing that, a relative majority over every other candidate. The medal will be awarded at the annual meeting of the Surgical Society of Paris.

April 5th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Care of the Feeble-minded.

THE Austrian Society for the Care of the Feeble-minded held its fourth annual conference in Vienna on March 22nd and 23rd, and the proceedings were of considerable interest to physicians as well as to teachers. The conference was not concerned exclusively with questions of therapeutics, but took up all problems connected with the general treatment, education, and after-care of feeble-minded persons of all ages. The opening address by the Minister of Education, Count Stürgkl, pointed out that it was the duty of society to do whatever might be possible for improving the condition of feeble-minded children. Schools for them had therefore been opened and would soon be increased in number to such a degree that these persons could be made comfortable without their infirmities being unnecessarily brought before the general public. One of the chief points in this scheme was the training of specially qualified teachers who could deal with these defectives better than parents could. Dr. Danziger, in a paper on the distribution of institutions for the care of feeble-minded persons, said that in the eastern part of the empire such institutions did not exist. Professor von Tauregg read a paper on Cretinism, in which he showed that in very many instances this condition was associated with maldevelopment of mental and moral qualities. He said that the administration of thyroid extract would work wonders, and if proper teaching was available persons originally helpless became easily capable of partially maintaining themselves by their earnings; for this, however, it was essential that there should be coöperation between medical men and teachers. An interesting paper, by Dr. Havorka, entitled "The Later Fate of the Feeble-minded," was read on the first day. His observations related only to persons who had since childhood been cared for in special homes and institutions. He said that the majority (55 per cent.) of these patients had to be transferred to lunatic asylums. About 30 per cent. were able to enter a school where the standard was higher, and there they were taught to do certain work, but as soon as they returned to their parents their mental condition deteriorated as a rule. It was therefore safest to keep such persons always in one of the higher institutes. The remainder of the children either died or found their way to the infirmary. A paper on Deaf-mutes was read, in a portion of which it was stated that such individuals were very often able to earn a tolerable livelihood without becoming much of a burden on their family and friends. In this country oral teaching is the rule in all schools for deaf-mutes, and the results are excellent if there is at least a remnant of hearing to build upon. In absolute deafness for noises and vowels the results are not so satisfactory, but even these unhappy persons may find suitable work. The progress made in the education of feeble-minded persons during the last 25 years in this country was well illustrated in a paper by Professor Spitzy. Whilst at the beginning of the before-mentioned period such persons could not be admitted into any public institution, there was now in each large city at least one school for them. It has been found that the disturbances of coördination form one of the most serious obstacles to bodily education, therefore teaching and occupation must be approximated as much as possible to the ideal of training this sense. At present in every school a search is made for symptoms of feeble-mindedness amongst the children. Various legal questions, relating to the subjects of marriage, inheritance, and exemption from military service, were discussed towards the conclusion of the conference.

The New Director of the Gynæcological Clinic.

The new clinic for gynæcology and obstetrics, which has been in use for only the last two years, had for its first director Professor von Rosthorn, whose appointment was received with so much pleasant expectation by the students, but he died after holding office barely one year. And it took another year before a successor for him was found in the person of Professor Wertheim. The new director has been a pupil of and assistant to Professor Schauta and Professor Chrobak, the leading Austrian gynæcological surgeons. Early in his career he turned his attention to the problem of cancer, and he worked out a method of treating malignant disease of the uterus which has become known all over the world as holding out some promise of success, if not undertaken too late, as permanent recovery is said to be probable in 60 per cent. of the cases operated on. Professor Wertheim, who is only 44 years of age, has also worked a good deal on the subject of puerperal sepsis, and is one of the surgeons who form what is here termed the "young Vienna school." He is very popular with both students and graduates, and his operating theatre in one of our suburban hospitals is always filled with foreign visitors, intent on watching his methods.

Questions of Paternity Decided by the Wassermann Reaction.

At a recent meeting of the Vienna Gesellschaft der Aerzte Dr. Hochsinger showed two infants, respectively three weeks and three months old, who gave a positive response to the Wassermann reaction and presented unmistakeable signs of congenital syphilis. Both the mothers and their husbands absolutely denied ever having suffered from syphilis, and the Wassermann test was negative in all four persons, but on being repeatedly pressed with inquiries both women confessed that they had been impregnated extra-maritally. Both of these unacknowledged fathers of the children on being afterwards examined showed a positive Wassermann reaction and they admitted having had syphilis. Here, then, was an explanation of the curious fact which is sometimes observed that a healthy child may be born between two syphilitic children. Dr. Matzenauer pointed out that such things happened, and he explained it by the theory that only maternal syphilis was transmitted to the fœtus and that disease of the placenta, which was the means of transmission, sometimes did not occur. Dr. Hochsinger's observation is extremely valuable on account of the light which it cast on the etiology of such cases. The negative result of the Wassermann test in the mothers was not surprising, since this test is sometimes known to fail, especially in the case of women during, and shortly after, pregnancy.

April 4th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE plague returns for the week ending Feb. 19th show 18,922 deaths for all India and Burma as compared with 15,286 for the week preceding. The Bombay Presidency reported 1116, Bengal Presidency 1966, the United Provinces 7420, the Punjab 3762, Burma 395, the Central Provinces 1693, and Rajputana 2471.

Children's Eyesight.

At a meeting of the Bombay corporation held recently the important question of the examination of children's eyesight in municipal schools was raised. The very necessary precaution now in progress in the United Kingdom whereby the school children are subjected to medical examination was referred to, and it is hoped that the Government of India will initiate a movement on similar lines in Indian schools. Some two or three years ago the military authorities in India detailed certain specialist officers in ophthalmology to visit all the army schools and examine the eyesight of soldiers' children who attend these institutions, and the results obtained were distinctly encouraging. Orders were issued that children with defective eyesight should have suitable glasses prescribed. In the case of army schools sanction was given for their improved lighting as funds became available. The principle to be observed in carrying out this was that the chief source of light should come from the north, subsidiary lighting to be by clerestory windows. Whenever possible buildings were to be built east and west, and when this was done the verandah roofs and sunshades were to be omitted on the north. The total glass area was never to be less than one-tenth the floor area. Areas under verandah roofs or shades were to be taken as seven-tenths of the actual area. The under surfaces of verandah roofs covering windows and of sunshades were to be painted white. The types of school books and atlases were inquired into, and those in which the type was too small were directed to be replaced by more suitable ones. New patterns of adjustable desks were approved, and their introduction ordered as funds became available.

The Coonoor Hospital.

The plans of the new Coonoor Municipal Hospital have been completed, the old hospital being unsatisfactory as far as accommodation was concerned, the wards being scattered over a large area and communication being difficult in the monsoon rains. Major R. Bryson, I.M.S., the superintending medical officer, has conferred a great boon on the public by his energy in helping to acquire a new site and putting matters in train for the erection of an efficient institution; the plans and estimates are now complete and are about to be laid before a general meeting. The Coonoor Municipal Hospital is quite a popular establishment, and the superintendent as well as his subordinate staff have carried out their work well with due regard to the wants and requirements of those upon whom they attend.

The Medical Officer of Health, Madras Corporation.

In consequence of the decision of the Government of India that an officer of the Indian Medical Service shall not in future hold the appointment of medical officer of health of Madras city, the post being thrown open to private practioners holding a Diploma in Public Health, Captain T. S. Ross, I.M.S., has been transferred from his present appointment as health officer to that of resident surgeon, Madras General Hospital.

The Water-supplies of Barracks.

The want of water laid on to some of the soldiers' barrack-rooms by a proper system of pipes is one of the most serious defects in military sanitation in India. In some cantonments, however, an excellent supply has been provided from standpipes in the vicinity of the lines, but the good effect is greatly lessened by the carriage of the water from these places either in the insanitary *mussacks*, or leather bags, used by the *bhistis* (native water-carriers) or by buckets which are used by the soldiers themselves when available. The water is stored in the barrack-room verandahs in galvanised iron receptacles which are never sterilised, and in some stations the lids which are supposed to be kept locked are often unprovided with locks. These tanks have a tap at the bottom, and as the flow from this is often too slow for the thirsty soldier he raises the lid and dips in his water-bottle or other vessel from above and contaminates the main supply.

March 18th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Practice in Australia.

CORRESPONDENTS from time to time ask for information and advice regarding practice in Australia. It is somewhat difficult to generalise about the conditions of a continent which stretches from south to tropical north, but it may be said that Australia presents no very special inducements for general practice and has some special drawbacks. The population of Australia is increasing very slowly, and the supply of home-trained medical men grows very rapidly. The Universities of Melbourne, Sydney, and Adelaide are turning out between 50 and 80 graduates every year and the numbers are not decreasing. It is natural that in the matter of public appointments the native practitioner considers he has a prior claim, and although he is not always preferred the proportion of home-filled posts is steadily growing. The practitioner coming from Europe or Great Britain would find the main difference in the amount of the fee, but there are compensating expenses. There are three broad classes of general practice in Australia. First, comes the practice in the large cities, which does not differ from similar work in the old world; next, practice in the country towns, to succeed in which to any great extent requires a good general acquaintance with operative surgery. Those practitioners not doing surgery may make a livelihood, but surgery is the factor that gives prominence to their colleagues. In Victoria especially, and in New South Wales in a lesser degree, most towns of any size are railway towns or within reach of a railway. In Queensland and South Australia this does not apply to so great an extent. The third class of practice is the little hamlet with a large outlying district, the true "bush" practice. There are many considerable incomes earned here, but the conditions of living are found almost insupportable by many sensitive and cultured natures, and the work is hard and trying. The workers of such practices rarely remain very long in one spot. Other drawbacks of country practice in Australia besides its frequent loneliness are the need of liberal and speedy means of transport, and in some States a trying climate. Any practitioner coming from the old country must expect, therefore, to find the conditions of success much the same in Australia as elsewhere. In speaking of buying practices in Australia a special warning should be given that such a procedure is always more of a speculation than an investment. The public are used to frequent changes of resident practitioners and it is rarely that any man can promise a succession of interest except in appointments, and even here the sequel is often disappointing. Practices are, of course, bought and sold daily, but the basis of valuation is nothing like so high as in the old country. Broadly speaking, anyone who is steady, self-reliant, and well qualified (it has to be remembered the Australian universities are turning out very highly-trained men) may expect to succeed in Australia to the extent he would succeed anywhere else, with the addition that in Australia his income would be somewhat larger. Unless some special circumstances influence particular cases it would certainly be unwise to throw up a comfortable living in England in order to begin anew in Australia.

School Inspection.

A beginning has been made in Victoria with the task of medically inspecting the children attending the State schools. Three qualified inspectors, Dr. Harvey Sutton, Dr. Jane Greig, and Dr. Mary Booth, were recently appointed, and a comprehensive scheme of procedure has been drawn up and the first schools dealt with. There is an average attendance of 150,000 children and a total roll of 230,000, so that it will evidently be some time before anything can be attempted outside the metropolitan area.

Treatment of Consumption.

The chairman of the Victorian Board of Public Health (Dr. B. B. Ham) recently made a statement in which he urged that the municipalities should assist in the provision of sanatoriums and hospitals for cases that required segregation. He said that the Government was prepared to find £10,000 for the construction of a hospital for such cases to contain 100 beds and to pay £2500 towards its maintenance if a like sum were contributed by the municipalities.

Melbourne Hospital.

At a special meeting on Feb. 4th the governors and subscribers confirmed the proposals to do away with the scandalous old system of electing the medical staff by popular vote. An advisory board is to be appointed annually consisting of 12 members, six being chosen by the committee, two each by the hospital medical staff, the University Council, and the Faculty of Medicine. This body advises the hospital committee, which may or may not accept the recommendation. Members of the staff retire at the age of 60. A term of appointment is for five years, and the maximum for any one position is 16 years. Medical officers to special departments are also provided for. The scheme was carried with one dissentient.

Vital Statistics in Australia.

The death-rate in Victoria for 1909 was the lowest ever recorded. The excess of births over deaths amounted to 17,113, the best record for 14 years. The metropolitan figures for Sydney for 1909 show a death-rate of 10·26 per 1000, the lowest on record, and the birth-rate was 25·81 per 1000, which is the highest record. The population of Sydney and suburbs is now estimated at 605,900.

March 5th.

THE NATIONAL SOCIETY OF DAY NURSERIES will have an exhibit at the Ideal Home Exhibition, which opens at Olympia on Friday, and should give those interested in crêche work an opportunity of seeing what is being done to provide suitable accommodation for infants whose mothers have to go out to work daily. The society is exhibiting a model for the guidance not only of those about to establish a crêche, but also of those who desire in existing day nurseries to reach the standard of efficiency requisite before affiliation with the society can be obtained.

Obituary.

CHARLES ERNEST MACKENZIE KELLY, M.D., M.S. LOND., F.R.C.S. ENG., L.R.C.P. LOND.

WE regret to record the death under exceptionally distressing circumstances of Dr. Charles Ernest Mackenzie Kelly, which took place at Witney, Oxon., on March 28th. Dr. Kelly had been suffering from severe gastric pain and, as appeared from the evidence at the inquest which it was unfortunately necessary to hold, he had taken an overdose of morphia for its relief. He was attended by Dr. William Collier, who, together with the Rev. C. W. O. Jenkyn, also a friend of Dr. Kelly, performed artificial respiration during the greater part of the night before he died, and did everything that was possible to resuscitate him. There was no reason whatever to suspect that the morphia had been administered with suicidal intent, and the coroner and the jury agreed fully that Dr. Kelly's death was due to misadventure from the effects of morphia administered with the intention of procuring sleep and relief from pain. Dr. Kelly was deputy coroner for the Western division of Oxfordshire, and it is no wonder that Mr. R. F. Cuthbert, the coroner, described the inquest as the most painful duty he had performed since he had been in the district, where the unfortunate gentleman had made himself extremely popular.

Dr. Kelly was the second son of Canon Kelly of Manchester, and had practised for 11 years in Witney. He studied at the Owens College, Manchester, and took the qualification of the London colleges in 1891. In 1896 he graduated M.B., B.S. of London University. In the following year he proceeded to the Doctorate and also to the Fellowship of the Royal College of Surgeons of England, whilst in 1898 he became a Master in Surgery of London. Besides obtaining these distinguished qualifications he passed the examination for the Membership of the Royal College of Physicians, but on settling down into general practice the custom of the College compelled him to relinquish that diploma, to the expressed regret of the President. In a modest but interesting unsigned communication to THE LANCET some 12 years ago Dr. Kelly explained the great success which had marked his examination course, for all his numerous honours degrees and diplomas were earned after he was a fully qualified man and in practice. His contention was that the higher tests need have no terrors for the post-graduate student if he has behind him a sound general education, and if he can bring stern method into the conduct of his studies. Dr. Kelly was medical officer and public vaccinator of the Witney district and workhouse, an assistant medical inspector of schools to the Witney and East Burford division of Oxford, a certifying factory surgeon, and a medical officer to the Great Western Railway. He was also senior bailiff of the town, to which post he was elected for a second year. He had identified himself with the welfare of his fellow-townsmen in every way, and his death has cut short both a distinguished professional and a useful civic career.

A memorial service was held in the parish church on the day of his funeral, which took place at Ashton-under-Lyne, near Manchester. Universal sympathy has been expressed for his widow and his daughter in their terrible bereavement, and it will be echoed by all his professional brethren.

GEORGE CARPENTER, M.D. LOND., M.R.C.P. LOND., M.R.C.S. ENG.

WE regret to record the somewhat early death of Dr. George Carpenter, which occurred in London on Easter Day, whereby the medical profession has lost one of the most able and hard-working investigators of the diseases of children in this country. Dr. Carpenter, who was the eldest son of Dr. John William Carpenter, was born in 1859, and received his professional training at St. Thomas's and Guy's Hospitals, after a general education at King's College School. He qualified as a Member of the Royal College of Surgeons of England and a Licentiate of the Society of Apothecaries in 1885, and the following year took his M.B. degree at London University, proceeding to the Doctorate in 1890. In 1889 he became a Member of the Royal College of Physicians. His first staff appointment was to the out-patient department of the Evelina Hospital for Sick Children, where he ultimately became physician, but he resigned this appointment after being elected to the staff of the Queen's Hospital for Children, to which he was full physician when he died, holding also a similar appointment to the North-Eastern Hospital for Sick Children.

Dr. Carpenter was an indefatigable worker at all that concerned children's diseases, and contributed considerably to their literature. He founded and was the editor of the *British Journal of Children's Diseases* and was chairman of the council of the Society for the Study of Disease in Children and editor of its reports before its incorporation in the Royal Society of Medicine, when he became president of its Section for the Study of Disease in Children, to the proceedings of which he frequently contributed papers and cases. He was also a vice-president of the society. He was the English editor of *Pediatrics*, the American journal of children's diseases, and was a corresponding member of the Pediatric Society of Paris, while his interest in another branch of medicine was shown by his membership of the Ophthalmological Societies of the United Kingdom and of France. Whilst he took a general interest in the pathology of childhood the study of congenital diseases of the heart occupied so much of his attention that he became an acknowledged authority in that field of study. In 1894 he published a book on the subject, the evident outcome of careful thought and arrangement of ideas, and his further experience on congenital cardiac affections was crystallised in the Wightman lectures delivered last year and published in abstract in our columns. Another careful compilation was his work on Congenital Syphilis of Children in Everyday Practice, published in 1901. He was, moreover, a frequent contributor to the medical journals, and of his papers published in such a manner we may recall the following which were printed in THE LANCET: The Differential Diagnosis of Abdominal Disease in Children; Tuberculosis of the Choroid; an address on Acute Pleurisy with Effusion; on Cases of Uncomplicated Myocarditis in Children; Lecture on Rearing of Children (Institute of Hygiene, February, 1907); A Fatal Case of Chorea associated with Double Optic Neuritis and Hyperpyrexia in a child of 3½ years; and Congenital Hypertrophic Stenosis of the Pylorus and its Medical Treatment.

Dr. Carpenter married only two years ago Helen Jeanne, daughter of Henry Baron d'Este, and every sympathy will be felt with this lady at her untimely bereavement.

JOHN BURNS, F.F.P.S. GLASG., J.P.

BY the death of Mr. John Burns, which occurred last week at his residence, 15, Fitzroy-place, Glasgow, that city has lost her oldest medical practitioner and a much-respected citizen. Mr. Burns, who was in his ninety-fifth year, was a Perthshire man and was engaged in practice till within a short time of his death, when he was laid aside with cerebral hæmorrhage. At the age of six he was bereft of both his parents, and spent some years with his uncle, a farmer in Methven. At first he adopted the teaching profession, but later went to Glasgow to study medicine. In 1846 he became a Licentiate of the Faculty of Physicians and Surgeons, Glasgow, and two years later a Fellow of the Faculty. In after years he occupied for a term the office of Vice-President of the Faculty. Immediately after graduation, in the capacity of medical attendant to a distinguished invalid in search of health, he visited the chief cities of Europe, Egypt, and Palestine. On his return he started practice in the Bridgeton district of Glasgow, and it was there that for over 60 years the main part of his work was accomplished. Shortly after his starting practice the city was visited by epidemics of cholera and typhus fever, and Mr. Burns was unwearied in his efforts to stay the ravages of these dreaded diseases. Ultimately he was struck down by typhus fever, and as the attack was a very severe one his ultimate recovery was unexpected. His skill and ability in his profession were acknowledged by all who came in contact with him, but in addition he had a warmth of affection and a generosity of disposition that made his character peculiarly attractive. Many anecdotes are told of his kindness to his patients. On one occasion a patient in straitened circumstances found on opening the pill-box that he had given her, not pills, but money to pay for more necessary things. On another occasion a medical friend met him coming out of a provision shop laden with bread and butter and eggs, and in answer to his chaff Mr. Burns said that he was taking the things to a patient and that they would do her more good than all the drugs he

could prescribe. As the result of his active and useful life he had acquired a competence and was looking forward to the time when he might retire from practice, when he was practically ruined by the failure in 1878 of the City of Glasgow Bank, in which he was a small shareholder. Though he was now in his sixty-fourth year, he set to work again with a vigour and elasticity which might have been looked for only in a man still in his prime, and with so much success that he was able to pass his declining years in ease and comfort. On the occasion of his jubilee as a doctor in 1896 Mr. Burns was presented with a brougham by his numerous friends in Glasgow and the West of Scotland. Soon afterwards he was made the recipient of a further mark of regard in the form of his portrait, painted by Mr. John P. Downie. The portrait was accepted by the Lord Provost of the day in the name of the corporation, and now hangs in the People's Palace on the Green in the immediate neighbourhood of the district in which for so many years Mr. Burns pursued his beneficent calling. In his will, after making provision for certain relatives and leaving numerous small legacies to friends, Mr. Burns has directed his trustees to distribute over £7000 amongst certain of the hospitals of Glasgow and Perth, and amongst various missions at home and abroad in which he was interested.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Ogata, who was one of the first Japanese to study medicine in Europe, has died at the age of 67 years. He was instrumental in founding the Japanese Red Cross Society and the Osaka Medical School, and was medical adviser to the Royal family. He contributed numerous papers to Japanese and German medical journals.—Dr. William H. Taylor, formerly professor of midwifery and gynæcology in the Miami Medical College, Cincinnati.—Dr. Henry K. Cushing, formerly professor of gynæcology in the Western Reserve University, Cleveland.—Dr. Ernest Wende, professor of dermatology in the University of Buffalo.—Dr. Henri Ricard, member of the French Senate for the Côte-d'Or.—Dr. Bauby, surgeon to the Toulouse hospitals and *professeur agrégé* in the University.—Dr. Candido Barata Ribeiro, professor of children's diseases in the University of Rio de Janeiro.—Dr. Joh. Krannhals of Riga, who for many years edited the St. Petersburg *Medizinische Wochenschrift*, has died from typhus fever.—Dr. Eduard Bethe of Stettin, whose name is well known as an accomplished entomologist. He was also a much respected practitioner. His age was 82.—Dr. Eduard Friedrich Wilhelm Pflueger, the Nestor of German physiologists, died at Bonn on March 16th. He was born in June, 1829, in Hanau, and at first studied law in Berlin, but after a few sessions abandoned that faculty for the medical where he distinguished himself even before his degree, which he took in 1857, by publishing an important research on the sensory function of the spinal cord. He soon became assistant to Professor Johannes Müller, and on the death of the latter, which occurred very shortly afterwards, he and Dr. E. du Bois Raymond were entrusted with the duty of continuing their deceased master's lectures. In 1859 he was appointed to the chair of physiology in Bonn, where he remained all the rest of his life. He published some two hundred numbers of the *Archiv für Physiologie*. These dealt in the earlier years chiefly with psychology and the physics of the nervous system, later with embryology and anatomy, and finally with problems of metabolism.

COLONIAL MEDICAL SERVICES.—*West African Medical Staff:* Dr. J. Tichborne, senior medical officer, Gold Coast, retires on pension. The following officers have been promoted: Dr. J. A. Pickels, from senior medical officer, Southern Nigeria, to be senior sanitary officer, Southern Nigeria; Mr. H B. S. Montgomery from medical officer, Gold Coast, to be senior medical officer, Gold Coast; and Dr. R. Laurie from medical officer, Southern Nigeria, to be junior sanitary officer, Southern Nigeria. Dr. W. H. Peacock has been appointed to the staff, Southern Nigeria.—*Other Colonies:* Mr. W. J. Woodman has been appointed assistant colonial surgeon in British Honduras, and Mr. J. F. O'Brien has been appointed a medical officer in the Straits Settlements.

Medical News.

THE UNIVERSITY OF LIVERPOOL: GRADUATION CEREMONY.—A moderate attendance of undergraduates and friends on March 23rd witnessed, in the Senate Room of the University, the periodical graduation ceremony. This was performed by Vice-Chancellor A. W. W. Dale, the following being duly presented by the Dean of the Medical Faculty and receiving their degrees:—

DEGREES OF M.B., CH.B.

Final Examination, Part II.—L. Buckley, J. A. Parkes, and J. F. Roberts.
Part I.—G. S. A. Bishop, I. C. Edwards, P. L. F. Nortjé, and I. J. Williams.
Second Examination, Part A.—R. G. Barlow, A. W. Bigland, A. V. Glendenning, R. Lee, J. H. Mather, M. T. Morgan, F. C. Plummer, Miss F. M. B. Price, H. Seddon, J. P. Thierens, F. Wilkinson, B. Williams, and T. O. Williams.
Part B.—R. Heald, N. P. Laing, and T. H. Martin.

DEGREE OF B.D.S.

Final Examination.—P. Kelly.
Third Examination.—H. T. Imlach.

DIPLOMA IN DENTAL SURGERY.

Second Examination.—G. Q. Dinn and W. Williams.
Third Examination.—J. Burns and J. Tyson.

After conferring the degrees the Vice-Chancellor gave some wholesome practical advice to the recipients.

UNIVERSITY OF DURHAM.—On April 2nd a Convocation was held in the Durham College of Medicine, Newcastle-on-Tyne. Professor Sir George Hare Philipson, the senior pro-Vice-Chancellor of the University, presided, and there was a large gathering, including Sir Thomas Oliver, Dr. Drummond, Professor R. Howden, Professor Bedson, Professor Stuart McDonald, Rev. J. H. Howe (Senior Proctor), and Mr. P. J. Henwood (Junior Proctor). The following medical degrees were conferred:—

M.D.—Henry Mounsey Braithwaite, Sidney Nix, and Thomas Leathard Wormald, College of Medicine.
M.D. (Practitioners).—John Brabant Bate, William Black, Robert Marshall, Charles Frederick Rudd, and Patrick Nunan Twomey, College of Medicine.
D.Hy. in absentiâ).—Thomas Matthew, College of Medicine.
M.S. (Master of Surgery).—Frederick Charles Pybus, College of Medicine.
M.B.—Jabez Ethelbert Dainty, Charles Marks, Charles Martin Brown, Bloomfield George Henry Connolly, William Sacco, Charles Sim Thompson, William Robert Elstob Unthank, and Charles Leslie Wigan, College of Medicine.
B.S. (Bachelor in Surgery).—John Frederick Bridge, Bloomfield George Henry Connolly, Jabez Ethelbert Dainty, Charles Marks, William Sacco, Charles Sim Thompson, William Robert Elstob Unthank, and Charles Leslie Wigan, College of Medicine.
B.Hy.—Eldred Curwen Braithwaite, Arthur Charles Greene, Isaiah Hodgkinson, and Andrew Banks Raffle, College of Medicine.
D.P.H.—Eldred Curwen Braithwaite, Joseph Buck, Arthur Charles Greene, Isaiah Hodgkinson, William Whittle Martin, James Booth Patterson, Agnes Melville Pringle, Andrew Banks Raffle, and Catherine Mary Richardson, College of Medicine.

At examinations in the Faculty of Medicine in March the following candidates were successful:—

DEGREE OF BACHELOR OF MEDICINE.—FIRST EXAMINATION.

Elementary Anatomy and Biology, Chemistry and Physics.—William Bell, College of Medicine, Newcastle-upon-Tyne; Arthur Butterfield, Edinburgh School of Medicine, and College of Medicine, Newcastle-upon-Tyne; Maurice Henry De Jersey Harper, Robert Rutherford Lishman, Edward Rowland Alworth Merewether (second-class honours), Gerald Douglas Newton, William Kerr Russell (first-class honours), and Sydney Thompson, College of Medicine, Newcastle-upon-Tyne.
Elementary Anatomy and Biology.—Cyril Armstrong, William John Bowden, Patrick Alexander Clements, Ishmael Gustavus Cummings, and Geoffrey Bede Egerton, College of Medicine, Newcastle-upon-Tyne; Henry Hawes Elliot, Guy's Hospital; Rev. Samuel Foskett, College of Medicine, Newcastle-upon-Tyne; David Rees Jones, Guy's Hospital; Francis Metcalfe, Frederick John Nattrass, Ernest Charles Gilchrist Parker, Jane Penman, and Hume Alexander Playfair Robertson, College of Medicine, Newcastle-upon-Tyne; Philip Savage, Guy's Hospital; and James Calvert Spence and Reginald Leslie Wright, College of Medicine, Newcastle-upon-Tyne.
Chemistry and Physics.—Arthur Causton Freeth, St. Mary's Hospital; James Melville Phillips-Jones, College of Medicine, Newcastle-upon-Tyne; Felix Stephens Rood, M.R.C.S., L.R.C.P., University College, London; and Eric Knowles Ryan, University of Sheffield.
Elementary Anatomy.—Leslie Lake Armstrong and Mary Lyle Haigh, College of Medicine, Newcastle-upon-Tyne.

SECOND EXAMINATION.

Anatomy, Physiology, and Materia Medica.—John Stanley Arkle (second-class honours), Robert Ernest Bell, and Herbert Grantham Dodd, College of Medicine, Newcastle-upon Tyne; Walter Armstrong Elliott, Edinburgh University; and Frederick John Henry Tobias Frere, Sydney Ellington Murray, William Somerville

Murray, Charles Henry Robson, Sidney Scott, and Herbert Joseph Shanley, College of Medicine, Newcastle-upon-Tyne.

THIRD EXAMINATION.

Pathology, Medical Jurisprudence, Public Health, and Elementary Bacteriology.—Sam Phillips Bedson, B.Sc. (second-class honours), and Joseph Jopling Brown, College of Medicine, Newcastle-upon-Tyne; Richard Murray Barrow, St. Bartholomew's Hospital; Ronald Greig Badenoch, Joseph Wilfrid Craven, William Leitrim Clements, Harold Fairclough (second-class honours), Cyril Gray, and James Kenworthy Johnston Haworth, College of Medicine, Newcastle-upon-Tyne; Cyril John Henderson, William Guy Lidderdale, Colin Mearns, Benjamin Bell Noble, Robert Wilkie Smith, James Alwin Colville Scott, and William Arthur Slater, College of Medicine, Newcastle-upon-Tyne; Russell Vyvyan Steele, University College, London; and Eleanor Walkinshaw, College of Medicine, Newcastle-upon-Tyne.

DIPLOMA IN DENTAL SURGERY (L.D.S.).—FIRST EXAMINATION.

Chemistry and Physics.—Tom Merchant Hopgood and William Hutson, College of Medicine, Newcastle-upon-Tyne.

UNIVERSITY OF EDINBURGH.—At a graduation ceremony held in the M'Ewan Hall on March 31st the degrees of Bachelor of Medicine and Bachelor of Surgery were conferred on the following:—

Thomas Alexander Adams, Alexander Archibald, Janet Armstrong, William Mervyn Biden, Evan Owen Bowen, Uriah Findlater Farrel Brown, John Cathcart, John Phethean Charnock, Bodj Raj Chopra, Lizzie Mackay Smith Clark, Gladys Hope Cook, Henry Anstey Cookson, Godfrey Christopher Dalton, Francis Antrobus Duffield, James Eaves, Alexander Harper Elmslie, Francis Samuel Brook Fletcher, Valentine Henry Gordon, Eduard Bernard Hoffman, Gaspard de Coligne Hugo, Ronald Bute Macfie, Gregor Mackenzie Miller, William Archibald Miller, Rhoda May Murdoch, Frederick Honorate Noronha, James Edward Russell Orchard, Peder Nielsen Pedersen, Stanley Pinion, Philip Roytowski, Arthur Clouston Russell, Morton Wood Ruthven, Thomas Cyril Smith, John Graham Smyth, Malcolm Stewart, Leonard Whitaker Owen Taylor, Mary Murray M'Calman Turpie, Tom Welsh, and Seymour Williams.

UNIVERSITY OF ABERDEEN.—The following degrees were conferred at a graduation ceremony on March 31st:—

Degree of Doctor of Medicine (*M.D.*).—Alexander Andrew Bisset, Archibald Deane, Francis Hernaman-Johnson, and James William Littlejohn.

Degree of Master of Surgery (*Ch.M.*).—Robert Williamson Asher Salmond.

Degrees of Bachelor of Medicine (*M.B.*) *and Bachelor of Surgery* (*Ch.B.*).—Hardress Brayshaw, Alex. John William Calder, Norman James Calder, Joseph Pirie Cameron, Robert Maxwell Chance, Charles Clyne, Ernest William Henderson Cruickshank, Clarence Edward Greeson, Thomas Curr Halley, Robert Hillhead Kellas, Charles McKerrow, Alex. Mitchell, Alex. Dawson Reid, William James Reid (second-class honours), *Robert Richards (second-class honours), Henry Edward Shortt, Colin Finlayson Simpson (second-class honours), Roland Sinclair, William Smith, David James Shirres Stephen, and Alex. Urquhart Webster.

* Passed Final Professional examination with "much distinction."

Degrees of Bachelor of Medicine (*M.B.*) *and Master in Surgery* (*C.M.*) (*Old Regulations*).—Stephen Galt Trail, Fraserburgh.

Diploma in Public Health.—Cuthbert Delaval Shafto Agassiz, James Clark Bell, Ernest Bisset, Donald Murray, Patrick Nicol, and Alexander Charles Profeit.

TRINITY COLLEGE, DUBLIN.—At examinations held recently the following candidates were successful:—

FINAL MEDICAL EXAMINATION.

Part I.—James M. Elliott, Thomas A. Watson, Frank Crosbie, John Gardiner, William O. Halpin, Robert E. Dunn, Matthew M'Knight, James Beckett, Oswald C. S. Tandy, Thomas M. Crawford, and Thomas W. E. Henry.

Part II., Midwifery.—William L. English, Adrian Stokes, Herbert de L. Crawford, Richard H. Mathews, Charles W. M'Kenny, Samuel R. Richardson, Andrees A. Louw, Hans Fleming, Charles M. Finny, Mary G. Caskey, Louis Trichard, Vicars M. Fisher, Robert E. Lee, John G. Ronaldson, Victor G. Best, William M. Johnstone, Walter E. Adam, Charles D. Hanan, and Cecil Grene.

INTERMEDIATE MEDICAL EXAMINATION.

Part I.—Francis Breen, Joseph A. Maxwell, Kenneth K. Drury, Reginald Johnson, Rev. Thomas Brook, Richard E. Tottenham Charles W. C. Myles, Edgar Ll. Nash, and Brian D. Crichton.

Part II.—Eileen Hewitt, James N. Armstrong, John Colgan, Georgina Revington, Jevan H. Powell, William P. Croker, Hugh G. Trayer, Herbert Bates, Dorothy K. Milne, Jerome H. Counihan, William O. W. Ball, Robert A. Flood, William E. Fetherstonhaugh, James H. Grove-White, Frederick B. M'Carter, Arthur P. Draper, Oswald V. Burrows, Robert H. Lyons, Kenneth K. Drury, Charles W. C. Myers, J. Florence Colquhoun, James N. G. Nolan, Robert E. Dunn, Edward Evans, Edwin F. O'Connor, Rev. Thomas Brook, Joseph A. Maxwell, Bernard G. Quinlan, Richard Grandy, Francis V. Agnew, and Marjory Chapman.

PRELIMINARY SCIENTIFIC EXAMINATION.

Physics and Chemistry.—David H. Hall, William E. Tyndall, George Buchanan, Frederick Harris, Etienne J. Malherbe, Arthur Brady, William F. Gibson, Joseph C. A. M'Calden, Robert J. B. Madden, Richard S. G. Halpin, William R. L. Waters, Frederick C. Fleming, George A. Bridge, Francis A. Roddy, Cecil G. Sherowitz, Thomas E. B. Beatty, Frank S. Gillespie, Charles O'Reilly, and William A. Ryan.

Botany and Zoology.—David S. Martin, William C. L. Shee, Thomas J. Kelly, William L. Bates, Robert C. Chapman, Charles P. Kelly, Edward D. Kinsey, William A. Ryan, Francis P. Mitchell, Charles D. M. Buckley, Edwin Boyers, Edmond Robinson, Robert J. B. Madden, William Hunt, and Cecil G. Sherowitz.

PREVIOUS DENTAL EXAMINATION.

Materia Medica.—George A. Yeates.

Physics and Chemistry.—William Y. Kingston.

FOREIGN UNIVERSITY INTELLIGENCE.—*Basle:* Dr. Henrichsen has been recognised as *privat-docent* of Psychiatry.—*Berlin:* It is believed that Professor Senator is about to retire. Dr. R. Krönig of Freiburg has been offered the second chair of Gynæcology in succession to Professor Bumm, who is to succeed Professor Olshausen on his retirement. Dr. Franz Müller, *privat-docent* of Psychiatry, has been granted the title of Professor.—*Berne:* Dr. Kehrer of Heidelberg has been appointed Professor of Midwifery and Gynæcology in succession to Dr. Peter Müller, retired.—*Bologna:* Dr. Luigi Vacari has been recognised as *privat-docent* of Surgery and Operative Medicine, and Dr. Vittorio Putti as *privat-docent* of Orthopædic Surgery.—*Düsseldorf* (*Academy of Practical Medicine*): Dr. S. Engel has been appointed *dozent* of Children's Diseases; Dr. Peter Jansen, *dozent* of Surgery; and Dr. Reinhard von den Velden, *dozent* of Medicine and Pharmacology. Dr. Ballowitz, Professor of Anatomy in the University of Münster, has been appointed to teach the same subject also in Düsseldorf.—*Frankfort:* Dr. Heinrich Bechold of the Institute of Experimental Therapeutics has been granted the title of Professor.—*Genoa:* Dr. Giulio Masini has been appointed Extraordinary Professor of Otology and Laryngology.—*Greifswald:* Dr. Paul Krömer of Berlin has been appointed Professor of Midwifery and Gynæcology, in succession to Professor Max Henkel.—*Kazan:* Dr. Dobrovolski of St. Petersburg has been appointed Extraordinary Professor of Hygiene.—*Kharkoff:* Dr. P. I. Shatiloff has been appointed Extraordinary Professor of Diagnosis and Propædeutics.—*Kiel:* Dr. Göbell has been appointed Director of the Surgical Polyclinic; Dr. Karl Behr has been recognised as *privat-docent* of Ophthalmology.—*Leipsic:* Dr. Hermann Heineke, *privat-docent* of Surgery, has been promoted to an Extraordinary Professorship.—*Moscow:* Dr. A. V. Martinoff has been appointed Professor of Clinical Surgery in succession to the late Professor P. I. Diakanoff.—*Munich:* Dr. Max Borst of Würzburg has been appointed Professor of General Pathology and Pathological Anatomy, and Director of the Pathological Institute in succession to Dr. Bollinger.—*New Orleans:* Dr. George S. Bel has been appointed Professor of Medicine.—*Palermo:* Dr. Spallita has been appointed Extraordinary Professor of Experimental Physiology.—*Parma:* Dr. Roncoroni has been appointed Professor of Neurology and Psychiatry.—*Philadelphia* (*University of Pennsylvania*): Dr. James K. Young, Professor in the Woman's Medical College of Pennsylvania, has been appointed Adjunct Professor of Orthopædic Surgery.—*Sassari:* Dr. Mario Pelagatti has been appointed Extraordinary Professor of Dermatology and Syphilography. *St. Petersburg* (*Military Medical Academy*): Dr. Shkarin, *privat-docent* of Pædiatry, has been appointed Extraordinary Professor.—*Strasburg:* Dr. H. Landolt, *privat-docent* of Ophthalmology, has been granted the title of Professor.—*Vienna:* Dr. Ernst Wertheim has been appointed Professor of Midwifery and Gynæcology in succession to Professor von Rosthorn, who died several months ago. Dr. Ludwig Jehle has been recognised as *privat-docent* of Children's Diseases, and has been appointed to the charge of the Children's Department in the General Polyclinic in succession to the late Professor Monti.

ROYAL COLLEGE OF SURGEONS OF ENGLAND: MUSEUM DEMONSTRATIONS.—The second annual series of demonstrations of specimens contained in the Museum of the Royal College of Surgeons will be delivered in the theatre of the College by the conservator, Professor Arthur Keith, and by the pathological curator, Professor S. G. Shattock. Professor Keith lectures to-day (April 8th) on Misplacements and Malformations of the Kidney and Ureter; on April 15th on Irregularities in the Development and Position of the Testicle; and on April 22nd on Malformations and Cysts of the Ovaries and Female Appendages. Professor Shattock will lecture on April 18th on Carcinoma, on April 25th on Tuberculosis, and on May 2nd on specimens illustrating Repair. The demonstrations will commence at 5 P.M., and are intended for advanced students and medical practitioners.

MEDICO-PSYCHOLOGICAL ASSOCIATION. — The dates of the professional and Gaskell prize examinations have been altered to July 6th and July 21st respectively.

UNIVERSITY OF OXFORD.—The Board of Faculty of Medicine has coöpted as a member of the Board Mr. John S. Fairbairn, B.M., M.A., Magdalen College, to hold office for two years from May 1st, 1910.

LONGEVITY.—The *Times* of April 2nd drew attention to the fact that 45 notices of death appeared in that issue, and 17 of these were of persons over the age of 70, whose average age was 79·8 years. Two were over 90, six between 80 and 90, and nine between 70 and 80.

THE FEEDING OF SCHOOL CHILDREN.—The benefit derived from the free breakfasts supplied during the winter months to a certain number of children at Hastings has been specially reported upon by the medical officer in that borough, and the town council on April 1st gave the necessary authority to the education committee to spend a sum not exceeding £100 on the provision of food for those children in need of it from April to October when the breakfasts are not provided.

PRESENTATION TO A MEDICAL PRACTITIONER.—At Hurstpierpoint, Sussex, on March 21st, Mr. Edward J. Parry, M.R.C.S.Eng., L.R.C.P. Lond., was presented with an illuminated address, a cheque value £100, and a book bearing the names of the subscribers, from patients and friends in the neighbourhood, "as a slight expression of regard and esteem." Mr. Parry, who has retired from the firm of medical practitioners at Hurstpierpoint, was also the recipient of other presents from admirers in the district where he has been for seven years.

THE HOSPITAL ALMONERS' COUNCIL.—The objects of this council are to select and arrange for the training of suitable candidates for posts as hospital almoners, to grant certificates of competency for such posts, and generally to take any steps which may be desirable for extending and developing the work of hospital almoners, and the report for the year 1909 shows that steady work has been accomplished in helping to check the widespread abuse of the out-patient departments of our hospitals. The Royal Free Hospital was the first institution to appoint an almoner, some 15 years ago, and since that time other hospitals has adopted the system. During the year the council has trained two more almoners for the London Hospital, and almoners have been provided for Westminster Hospital, Great Ormond-street Hospital for Sick Children, and St. Thomas's Hospital. It is hoped that three almoners will shortly be able to take up work at Leeds. The offices of the council are at Denison House, 296, Vauxhall Bridge-road, London, S.E.

MALARIA: ITS ETIOLOGY AND PREVENTION.—A prize of 1000 fr. (£40) is offered by the Lombard Committee of the National League against Malaria to the Italian physician who will submit to the said committee "il miglior lavoro di indole scientifico-pratica sul problema della lotta contro la malaria" (the best work of a scientific and practical tenor on the question of how to combat malaria). The conditions are these: The essay or monograph, in manuscript or in print, must be sent in not later than May 20th, 1910; and, if in print, must not have seen the light before 1908. The essay or monograph, bearing its author's name, must be addressed to the "Consiglio Lombardo della Lega Nazionale contro la Malaria," at its headquarters, "Gli Istituti Biologici della R. Università di Pavia." The successful competitor must consign to the President of the Lombard Committee 30 copies of his work. If presented in manuscript it will have to be published within the year 1910, and copies to the above number consigned to the President, after which the successful competitor will be entitled to the prize. The committee charged with examining the competing essays or monographs and determining the first in point of merit consists of the following gentlemen: Dr. Camillo Golgi, professor of general pathology, and Dr. Carlo Forlamini, professor of clinical medicine, both of the University of Pavia; Dr. Giovanni Battista Grassi, professor of comparative anatomy and entomology in the University of Rome; Professor G. Bordoni Uffreduzzi, medical officer in chief of the commune of Milan; and Dr. L. Pampana, of the same province. The donor of the prize is Signor Giulio Hyler.

A DEVONSHIRE CENTENARIAN.—Miss Mary Bury Cobbett, of 15, Queen's-terrace, Exeter, celebrated the hundredth anniversary of her birthday on March 29th.

THE MEDICAL SOCIETY OF LONDON.—A special meeting will be held on Monday, April 18th, at 8.30 P.M., at which a paper on Inheritance in Hæmophilia will be read by Dr. W. Bulloch and Mr. Paul Fildes. Amongst those who are expected to be present and take part in the discussion are Sir Almroth Wright, Professor W. Osler, Professor Karl Pearson, and Professor W. Bateson.

A CAMBRIDGE MEDICAL SOCIETY IN THE MANCHESTER DISTRICT.—It is proposed to form a society of medical men who have studied at Cambridge, to comprise those practising in Manchester and the surrounding district. A meeting to constitute the club will be held at the Queen's Hotel, Manchester, on Wednesday, April 27th, at 6 P.M., and will be followed by a dinner at 7 P.M. Dr. Alfred Godson of Cheadle has accepted the post of president for the first year. Any Cambridge medical men residing in the district who have not received notice of the meeting are requested to communicate with the provisional secretary, Dr. E. B. Leech, 242, Oxford-road, Manchester.

THE NEW MEDICAL BUILDINGS AT MCGILL.—The new buildings of the medical faculty of McGill University are to be opened on June 6th and 7th. It is intended to mark their inauguration by a réunion in Montreal of as many as possible of the medical graduates of McGill. Word has been received from members of each of 45 classes which have passed through the faculty of medicine, and, without exception, each class has signified its intention to unite as many of its members as possible at a class réunion in Montreal for the opening festivals. The magnificent new buildings have been built to replace those which were destroyed by fire in 1907, and they have been erected at a cost of about $750,000. Lord Strathcona contributed considerably more than half of this sum, and he gave, in addition, the site, close to the old medical buildings, upon which the new structure has been erected. The Governor-General is to preside over the inauguration ceremonies, which will be arranged on an extensive scale.

RECORDS OF DETENTION IN PADDED ROOMS AT WORKHOUSES.—The Local Government Board has addressed a circular letter to the boards of guardians stating that its attention has recently been drawn to the need of some record of cases where inmates of workhouses are detained in the padded rooms at those institutions, with which the Commissioners in Lunacy have expressed their agreement. The Board requests that in those unions where there is a padded room at the workhouse the guardians will give directions for the necessary record to be kept of every case of detention in the padded room. The record should show the date and duration of the detention, the reasons for the treatment, and what directions were given by the medical officer in the matter. Any such entries should be brought to the notice of the Commissioner in Lunacy on the occasion of his next visit to the workhouse. The letter adds that the Commissioners consider that in no case should a person be detained in a padded room at the workhouse except under the previous order or with the concurrence or approval of the medical officer.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Midwives Bill.

Viscount WOLVERHAMPTON, as Lord President of the Council, has introduced a Midwives Bill into the House of Lords. Its purpose is "to amend the Midwives Act, 1902." The measure has been printed, and a memorandum attached to it states that it is for the most part founded upon the report of the Departmental Committee appointed to consider the working of the Midwives Act, but it departs from the recommendations of that committee in one or two details. Briefly stated, the main objects of the Bill are: (1) the reconstitution of the Central Midwives Board; (2) to make additional provision to deal with the enrolment and suspension of midwives and the notification of their practice; (3) to regulate further the powers of local supervising authorities; and (4) to make provision for the payment of the fees of medical practitioners called in on the advice of midwives.

Clause 1 of the Bill alters the constitution of the Central Midwives Board. It is proposed that the Board shall consist of—(*a*) two persons (one of whom shall be a woman) to be appointed by the Lord President of the Council, and one person to be appointed by the Local Government Board; (*b*) four duly qualified medical practitioners, one to be appointed by the Royal College of Physicians of London, one by the Royal College of Surgeons of England, one by the Society of Apothecaries of London, and one by the British Medical Association; (*c*) two certified midwives to be appointed, one by the Incorporated Midwives Institute, and one by the Royal British Nurses Association; and (*d*) four persons to be appointed, one by the County Councils Association, one by the Association of Municipal Corporations, one by the Society of Medical Officers of Health, and one by the Queen Victoria's Jubilee Institute of Nurses.

The effect of the reconstitution will be to increase the number of the Board from nine to 13 members, representation being given to the following bodies, who were previously unrepresented:—(1) The Local Government Board; (2) the Association of Municipal Corporations; (3) the Society of Medical Officers of Health; and (4) the British Medical Association. The member appointed by the last-mentioned Association must be a medical practitioner. No special qualification is prescribed in the case of members appointed by the other new bodies. In addition to this increase in numbers, the qualifications of the members appointed by the Incorporated Midwives Institute and the Royal British Nurses Association have been altered. In the future the members appointed by these bodies must be certified midwives. At present the member appointed by the Incorporated Midwives Institute must be a medical practitioner, whilst with respect to the member appointed by the Royal British Nurses Association no special qualifications are required.

The future revision of the constitution of the Central Midwives Board is provided for by Clause 2. It lays down that the Board may at any time represent to the Privy Council that it is expedient to modify its constitution either by (*a*) increasing or diminishing the number of persons appointed by any body or person; or (*b*) abolishing the power of appointment by any body or person; or (*c*) conferring on any body or person a power of appointment of one or more persons; or (*d*) altering the term of office or qualifications of any members. The clause provides that the scheme thus formulated by the Central Midwives Board is to lie on the table of both Houses of Parliament for 40 days, and if no address against its contents is passed by either House the Privy Council may proceed to enforce it by Order in Council.

Extended powers of framing rules to define the conditions under which a midwife may be suspended from practice are proposed to be conferred by Clause 8. The Board may under it frame rules—(*a*) authorising the suspension of a midwife from practice for such period as the Board thinks fit, in lieu of striking her name off the roll, and to suspend from practice until the case has been decided, and (in the case of an appeal) until the appeal has been decided, any midwife accused before the Board of disobeying rules or regulations or of other misconduct; and (*b*) authorising the local supervising authority which takes proceedings against a midwife either before a court of justice or the Central Midwives Board to suspend her from practice until the case has been decided.

Under Clause 10 (offences by midwives) the Board is given the discretion of prohibiting a woman whose name it removes from the roll from attending women in childbirth in any other capacity. This clause may be enforced by fine.

Clause 11 deals with the notification of practice. Where a certified woman who has not given to the local supervising authority such a notice as is required by the principal Act attends any woman in childbirth in any capacity other than that of midwife, and a duly qualified medical practitioner is not present at the time of the birth, she shall, within 48 hours from the birth, give to the local supervising authority notice in writing of the fact that she so attended.

Powers are given to local supervising authorities to contribute to the training of midwives, and Clause 15 gives them powers of entry. The clause runs as follows: "For the purpose of exercising the powers of supervision over midwives conferred on local supervising authorities, any officer appointed by such an authority for the purpose may at all reasonable times enter any premises which he has reason to believe to be a lying-in home conducted for profit within the area of the authority, and in which he has reason to believe that a certified midwife is employed or practises, or that a woman not a certified midwife practises in contravention of the principal Act, and any person who wilfully obstructs any such officer in the performance of his duties shall on summary conviction be liable to a fine not exceeding *five* pounds."

Provision is made in Clause 17 for the payment of fees of medical practitioners called in on the advice of midwives in cases of childbirth. The text of the clause adequately explains the machinery. It runs thus: "(1) Where a duly qualified medical practitioner has been summoned upon the advice of a certified midwife attending a woman in childbirth to render her assistance in a case of emergency in pursuance of any rule framed by the Central Midwives Board, he shall, subject to regulations to be made by the Local Government Board, be entitled to recover from the board of guardians of the Poor-law union in which the woman resided such fee in respect of his attendance as may be fixed by those regulations. (2) The payment of such fees may, if the board of guardians think fit, be treated as relief by way of loan and be recoverable accordingly. (3) Every board of guardians shall in each quarter send to every local supervising authority concerned a list of the cases within the area of the authority in respect of which fees have been paid by the board of guardians under this section."

Clause 18 lays down that "the General Medical Council may for the purposes of section 3 of the principal Act, act through their executive committee instead of through the English Branch Council."

Vital Statistics of England and Wales.

A general abstract of the births, deaths, and marriages registered in England and Wales during the year 1909 has been issued, but the figures are subject to revision. The population of England and Wales in the middle of 1909 is estimated at 35,756,615. The total of marriages for the year was 260,259; of births, 914,621; and of deaths, 518,075.

HOUSE OF COMMONS.

THURSDAY, MARCH 31ST.

Public Health at Germiston (Transvaal).

Mr. O'GRADY asked the Under Secretary of State for the Colonies how many irregular cemeteries existed for the burial of natives employed in the mines in the Germiston municipality, in the Colony of the Transvaal; whether he was aware that natives were indiscriminately interred in the numerous scattered loci to suit the convenience of the mines, that the bodies were superficially disposed of in the huge mine dumps close to residences, and that the bodies had no mark of identification and were often not enclosed; whether he was aware that, in view of the danger to public health arising from this method of burial, protests had been lodged by the police surgeons of the neighbourhood; and, if so, would representations be made to the Government of the Transvaal to end such a state of things.—Colonel SEELY replied: This being entirely a matter for the Transvaal Government, it would be both unusual and undesirable to take the action proposed by my honourable friend.

Mr. O'GRADY: Have these facts been brought to the attention of the Colonial Office before?—Colonel SEELY: I am not prepared to admit what is stated in the question. I have no knowledge of it.

Mr. O'GRADY asked the right honourable gentleman whether, seeing that under the new constitution granted to South Africa for the Union Parliament, it was laid down that issues affecting the general welfare of the natives of South Africa would be reserved to the Imperial Parliament, and having regard to the congregations of native subjects of foreign Powers, such as of Portuguese and other nationalities from foreign territories close by, who were indentured and under contract in the Transvaal and other South African mines, and to the presence of Asiatics who were resident in the compounds at the time, whose welfare was also under Imperial supervision, would the Secretary of State for the Colonies obtain information relative to the outbreak of infectious disease in the Germiston and contiguous municipality of Johannesburg in the Transvaal Colony, and the incidents leading up to the dismissal of Dr. Michael Arthur Curry, the medical officer of health during the period under review, and to the treatment in general of their medical officials; and whether such treatment acted prejudicially to the health of the foreign natives and the white workers in the mining districts of South Africa.—Colonel SEELY answered: The matters referred to in my honourable friend's questions are matters for the Transvaal Government to consider, and not for the Secretary of State, who does not exercise any authority in respect of them. No complaints regarding foreign natives have reached the Secretary of State through any diplomatic channel.

Drainage in the Dunmoran District.

Mr. SCANLON asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been directed to a resolution of the Sligo county council calling upon the Congested Districts Board to make a grant for the improvement of the Dunmoran drainage district in the Drumoor West union of county Sligo; and whether he would cause this matter to be submitted for immediate consideration of the Board, as some drainage improvement was essential in the interests of sanitation and public health.—Mr. BIRRELL replied: I am aware that the Sligo county council have passed a resolution to the effect stated in the question, but the Congested Districts Board have decided that in such cases they cannot undertake drainage works except in connexion with estates purchased by them.

The Sick Berth Staff of the Royal Navy.

Lord CHARLES BERESFORD asked the First Lord of the Admiralty whether he could see his way to make an improvement in the pay and status of the sick berth staff of the Royal Navy.—Mr. MCKENNA (by written answer) replied: The position of the sick berth staff in the matter of pay and advancement was one of the subjects dealt with by the Committee on the Naval Medical Service, whose recommendations are now under the consideration of the Admiralty.

The Blue Book on Infant Mortality.

Mr. POINTER asked the President of the Local Government Board whether he could state when the Blue Book on Infant Mortality, promised by him some time ago, would be published.—Mr. BURNS wrote in reply: Some progress has been made with the report referred to, but I am not in a position to fix a date for its publication.

MONDAY, APRIL 4TH.

The Children's Infirmary, Carshalton.

Mr. DAWES asked the President of the Local Government Board whether he was aware that in November last the managers of the Children's Infirmary, Carshalton, submitted to the Local Government Board certain proposals for increasing the accommodation from 800 to 1200 patients by the provision of the necessary additional staff quarters and isolation wards; and, if so, would he say what reply had been given by the Board.—Mr. BURNS replied: The managers of the Metropolitan Asylums Board on Nov. 23rd last submitted to my Department proposals for certain extensions to the Children's Infirmary at Carshalton. The proposals involve the expenditure of a very large sum, estimated to exceed £50,000 or £60,000. In view of the large margin of spare accommodation in other institutions belonging to the Asylums

Board, I am of opinion that the whole question of the accommodation of the various classes of patients in the charge of the Asylums Board needs careful consideration, and I am in correspondence with the managers on the subject.

Experiments on Living Animals.

Mr. DOUGLAS HALL asked the Secretary of State for the Home Department whether he would direct that in the forthcoming annual return under the Cruelty to Animals Act, 39 and 40 Vic., c. 77, the reasons should be set out why, in experiments performed on dogs without the use of anæsthetics, it was necessary to employ those animals to prevent the object of the experiment being frustrated; and whether any steps were taken, and, if so, what steps, to test the soundness of the reasons given in these cases for making the experiments on dogs.—Mr. CHURCHILL answered: In dealing with certificates for experiments on dogs, whether with or without the use of anæsthetics, the reasons given for making the experiments on dogs are always carefully scrutinsed by my expert advisers; and if there is any doubt special inquiry is made before the certificate is allowed as to the possibility of performing the experiments on other animals. I do not think anything would be gained by giving these reasons in the annual report.

Mr. DOUGLAS HALL further asked the right honourable gentleman what was the total number of licences and certificates to experiment on living animals applied for during the year 1909, and the total number of licences and certificates granted for that purpose in that year.—Mr. CHURCHILL replied: 483 licences were in force during 1909. Of these, 94 were new licences granted in 1909; the remainder were renewals. No applications for licences were refused in 1909. As no applications come before the Secretary of State unless they are first recommended by the highest scientific authorities a refusal is naturally of rare occurrence. As regards certificates, the Secretary of State does not grant certificates—he has only a power of disallowance. I cannot at present state the number of certificates in force during the year, but information will be given in the annual return, which will probably be published in June. The number of certificates totally disallowed was eight, and in many other cases the Secretary of State disallowed certain procedures that were proposed or in other ways limited the scope of the certificate.

Grants in Aid to Irish Hospitals.

Answering Mr. GODFREY COLLINS, Mr. HOBHOUSE (Secretary to the Treasury) said: The grant in aid of Irish hospitals (subhead D of the Vote for Hospitals and Charities, Ireland) is £15,850. There is no grant in aid to Scottish hospitals.

TUESDAY, APRIL 5TH.

An Outbreak of Cow-pox.

Mr. BARNES asked the Under Secretary of State for the Home Department whether he could now state the result of his inquiry into the outbreak of cow-pox at Vale Farm, Pinner-road, Sudbury, as a result of which four persons contracted the disease; and whether he could state the decision he had come to with regard to the advisability of extending the Workmen's Compensation Act to cover this and other diseases of a similar nature.—Mr. MASTERMAN replied: The Secretary of State has communicated with the Local Government Board and the Board of Agriculture, and has received reports from which it appears that the outbreak was one of cow-pox. The effects, however, on the workmen, as described in the particulars which the honourable member was good enough to send him, seem to have been exaggerated. The Secretary of State understands that the elder Wigmore was off work three weeks, during which time he received half wages, that he did not go to a hospital, and that he is now recovered; and that the younger Wigmore was only slightly affected and off work for three days. The question of adding this disease to those included in the Workmen's Compensation Act is being considered in consultation with the other departments, and my right honourable friend has not yet been able to come to a decision in the matter.

Fatalities at Hemel Hempstead Workhouse.

Answering a long question put by Mr. MORTON,

Mr. BURNS said: The circumstances connected with the lamentable bathing fatalities which occurred at the Hemel Hempstead workhouse at the beginning of October were most carefully investigated by officers of my department and received my close personal attention. The letters addressed to the board of guardians and to the Workhouse Nursing Association on Dec. 8th indicated the considered conclusions of the department and I have no reason to depart from them. The guardians have now entirely reconstituted the nursing staff and I do not doubt that the action which has been taken will prove effective. I am satisfied that no advantage could result from further inquiry into the circumstances which occurred six months ago and have already received the fullest investigation, and I am not prepared to direct such inquiry. I have, of course, no jurisdiction or responsibility with regard to proceedings before the coroner nor in connexion with the subsequent prosecution.

The Sanitation of Welsh Villages.

Mr. REES asked the President of the Local Government Board whether he had in contemplation any scheme for the improvement of sanitation and water-supply in villages in Wales.—Mr. BURNS answered: It is not the province of the Local Government Board itself to make schemes for the improvement of sanitation and water-supply. Under the Public Health Act, 1875, and other Acts the necessary powers for these purposes are vested in the urban district councils and rural district councils. The Board has sanctioned many loans for such improvements in villages in Wales, and applications for sanction to further loans are under consideration at the present time. The Board is doing what it can to urge and encourage local authorities to carry out such schemes where they appear to be necessary or desirable.

WEDNESDAY, APRIL 6TH.

Deaths in County Asylums.

Mr. CLYNES asked the Under Secretary of State for the Home Department whether he was aware of the grievance felt by relatives of patients who died in the county asylums, and who had been chargeable to boards of guardians, because of the description pauper patient in the notice of death sent out from the asylums; and whether, having regard to the fact that the full cost of maintenance of many such patients had been met by relatives or friends, he would cause to be eliminated the word pauper from the Form (No. 21) of Notice of Death prescribed in the rules laid down by the Commissioners in Lunacy.—Mr. MASTERMAN replied: The terms "private" and "pauper" are in common use to mark a necessary distinction, and as the terms are defined in the Lunacy Acts they could not be changed without legislation. The Secretary of State may point out that although the whole expenses of "maintenance" (as defined by Section 287 of the Lunacy Act, 1890) of patients classed as "paupers" are often met by relatives or friends, these "expenses of maintenance" do not include any charge for the cost of the building in which he is housed. If a rent-charge were exacted, it would mean a payment of about 4*s.* or 5*s.* a week beyond the so-called "maintenance."

BOOKS, ETC., RECEIVED.

AMERICAN MEDICAL ASSOCIATION, Chicago.

New and Non-official Remedies, 1910. Containing Descriptions of the Articles which have been Accepted by the Council on Pharmacy and Chemistry of the American Medical Association prior to Jan. 1st, 1910. Price, paper, 25 cents; cloth, 50 cents.

WESTERN OPHTHALMIC HOSPITAL.—Assistant Surgeon.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon. Salary at rate of £80 per annum, with board, rooms, &c.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of a vacancy as Certifying Surgeon under the Factory and Workshop Act at Kilsyth, in the county of Stirling.

Births, Marriages, and Deaths.

BIRTHS.

CUNNINGHAM.—On March 29th, at 29, Sussex-place, Regent's Park, the wife of J. F. Cunningham, F.R.C.S., of a son.

DICKEY.—On March 21st, at Whitehall-gardens, Gunnersbury, W., the wife of W. Craufuird Dickey, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

GAIRDNER.—On April 3rd, at Pretoria, the wife of John Francis Robert Gairdner, M.B., M.R.C.S., of a son.

WILLIAMSON.—On April 3rd, at Springfield-road, Leicester, the wife of Lieutenant-Colonel J. G. Williamson, R.A.M.C. (retired), of a daughter,

MARRIAGES.

CADDY—PAYTON.—On March 29th, at the British Consulate, Calais, and at the English Church, Adrian Caddy, F.R.C.S., of Calcutta, to Evelyn Mary, fourth daughter of Charles A. Payton, M.V.O., H.B.M.'s Consular Service.

SMITH—DYER.—On April 4th, at St. Margaret's, Westminster, by the Rev. Cecil Knox, M.A., Edwin Smith, M.D. Lond., Barrister-at-law, son of Edwin Smith, retired Collector of Inland Revenue, to Edith Catherine, younger daughter of Henry N. Dyer, both of Balham, S.W.

WILLAN—SHAWYER.—On March 31st, at St. Cuthbert's Church, Carlisle Robt. J. Willan, M.S., F.R.C.S. Eng., second son of John Willan, J.P., Shincliffe, near Durham, to Dorothy Eleanor, second daughter of J. B. Shawyer, Carlisle.

DEATHS.

BELCHER.—On March 23rd, the Rev. Thomas Waugh Belcher, D.D., M.D., M.Ch. Dub., F.R.C.P. Irel., Rector of Frampton-Cotterell, Bristol, aged 79 years.

MILWARD.—On March 31st, at Rotton Park-road, Edgbaston, Birmingham, Frederic Victor Milward, F.R.C.S., aged 40 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE STATE AND CHILD LIFE.

"THE securing of a fair chance for our boys and girls touches the future life of the State. Compassion has suggested an increasing provision by the public for the needs of the old, but after all the old belongs to the past; the future rests with the young; and it is unquestionably in our power, as a feature in the system of our civilisation, so to deal with our young people that the miseries which are so marked a feature of our modern life shall be greatly abated." So said Mr. Winston Churchill at Brighton on April 2nd, where the Home Secretary had an opportunity of seeing the practical work of the Brighton Police-aided Scheme for Clothing Destitute Children, an excellent undertaking of which we have made previous mention at different times. During the winter months the police frequently observe children insufficiently clothed in the streets, and exposed to consequent danger and suffering. The constable takes the names and addresses of these children and reports the matter to the superintendent of his division. The homes of the children are then visited by the police, and if it is found that the father is in employment, earning sufficient to provide clothing for his children, he is told to have them properly clothed at once or he will be prosecuted under the Prevention of Cruelty to Children Act. But if it is found that the parents are out of employment and the case is a deserving one, an allocation of suitable clothing is made, and the children are told to attend at a building used by the police as a wardrobe where the clothing is distributed. Before distribution each article is stamped, and a copy of that stamp is supplied to the pawnbrokers with a view of preventing the clothing being improperly dealt with by unscrupulous persons. But the work has not ended here. In the course of inquiries respecting little children it has been found that there are families with young girls ranging from 14 to 19 years of age, whose parents can scarcely feed, much less clothe them. They are unable to gain employment, there being no factories in Brighton, and the only course open for them is to enter domestic service. Here also the police have, as it were, filled the void. After the strictest inquiry many have been provided with a servant's complete outfit, and, what is more, with a situation. Since February, 1904, when the scheme was initiated, no fewer than 4829 children have been clothed and 188 young girls placed in domestic service.

Mr. Churchill saw 80 ragamuffin boys and girls transformed into well-dressed children, well-dressed, be it said, with due regard to health rather than appearance' sake, particular attention being paid more to the under garments than the outer ones. The Home Secretary expressed his admiration for the scheme, and said he was not without hopes that Sir Edward Henry might see his way to extend it to the great metropolitan area. The scheme, Mr. Churchill said, opened up a new sphere of police activity and not only gave a powerful influence to social work, but would, he thought, enhance the popularity of the police force generally.

INFANT MORTALITY AND THE "SOOTHER."

To the Editor of THE LANCET.

SIR,—Dr. Burnet has done good service in bringing this important subject under notice, and I trust you will give effect to his recommendation and allow the matter to be discussed in your columns. Its consideration is all the more urgent when we remember that summer will soon be here again, at which time we may hope to be favoured with some hot weather. While the use of the rubber "soother" and the long-tube feeding-bottle is to be condemned at all times, the evil is much greater during the warm season.

It is impossible to describe in detail the possible bad effects that may supervene when the articles just mentioned are employed, but it can hardly be doubted that they play some part in causing the deaths of many infants, to say nothing of the local injuries and disturbances to general health that may accrue to their use. For instance, it is not improbable that the "dummy-teat" may aid in the spread among infants of such diseases as enteric fever, zymotic enteritis, tuberculosis, &c., while in the hot weather of summer it is most difficult to keep the long-tube feeding-bottle clean, and, if not clean, rapid multiplication of innumerable bacteria takes place within the tube. It can easily be understood that gastro-enteric disturbances and much ill-health may arise from this cause.

As to the best means of dealing with the matter, I am at one with Dr. Burnet in believing that the manufacture and sale of the articles should be forbidden. Some little time ago I saw recorded the fact that in one of the countries on the Continent the sale of long-tube feeding-bottles had been prohibited by law. Such a recommendation as that just mentioned is, therefore, quite within practical politics, but I am afraid it is hopeless to expect any legislation in this matter in the immediate future.

In the meantime we must adopt other means to try to mitigate the evil, and in my opinion some good might be done by educative measures. While I do not think that the distribution of printed leaflets should be neglected, I doubt if they will do much good. The chances are that such leaflets will not be read by the class of persons who are the worst offenders. The suggestion that large posters containing warnings of the risks involved should be displayed is admirable, for if conspicuously placed they would certainly attract the attention of the public. Much more, however, can be done by verbal instruction, which could be given through the medium of various officials. With the adoption of the Early Notification of Births Act (1907) by a local authority one or more lady health visitors are appointed, and these ladies in the course of their visitations can distribute much valuable information regarding feeding-bottles and "soothers." In some districts the work of these ladies has been very successful, and many of the mothers, especially the younger ones, not only eagerly look forward to future visits from these ladies, but also endeavour faithfully to carry out the instructions received. Members of hospital staffs, district nurses, and those engaged in charitable work can also assist. Medical practitioners should take every opportunity of pointing to the dangers likely to arise. There is a good deal of truth in Dr. Burnet's assertion that they are often remiss in this respect, for they too frequently maintain a position of masterly inactivity. They must expect rebuffs, because in many instances, when the advice is tendered the information is received with the utmost incredulity. While it must be admitted that the evil is greater among the poor it is unfortunately true that those in good positions are not blameless. Some amelioration might be expected if the educated classes could be made to realise their error and could be persuaded to assist in educating the ignorant by themselves setting the example. Education by popular lectures and the instruction of the senior girls in all schools in the management of infants must not be forgotten. The latter can hardly be over-estimated, for is it not the case that many of these girls on leaving school are given the charge of their baby brothers and sisters, while in populous districts especially a number become mothers at a very early age?

Personally, I have not experienced much difficulty in persuading mothers to give up using the long-tube bottle, but it has been otherwise with the rubber "soother." The use of the "soother" cannot be supported on medical grounds, and it may be remarked that if an infant is not accustomed to have a "comforter" he or she will never miss it. It might be an excellent plan if among the poor an arrangement could be made so that long-tube feeding-bottles would be exchanged for boat-shaped or other more suitable varieties, a practice that is in vogue in some children's hospitals.

The matter could be dealt with indirectly in various ways, but space forbids my traversing these by-paths, however interesting that might be. From what I have said it will be apparent that I believe that some good might follow a vigorous campaign of education, but, in conclusion, I would again submit that the most satisfactory remedy would be the prohibition by Act of Parliament of the manufacture and sale of long-tube feeding bottles and rubber "soothers."

I am, Sir, yours faithfully,

Edinburgh, March 22nd. JOHN ALLAN.

THE SUGGESTED COMMUNICATION OF LEPROSY BY MEANS OF CAVIARE.

A NOTE in the *Torg. Prom. Gazeta* of the Russian Government says that the Medical Council, in view of an article that has appeared in an American paper alleging the possibility of the spread of leprosy in America from Russian caviare, declares that "after a detailed examination of the question on all sides there is not the slightest ground for ascribing the rôle of 'leprosy disseminator' to caviare, the more so in that it is mostly the poor who suffer from leprosy and they never use caviare; and further, in scientific works by various authorities who have investigated this disease there is no word of the bacillus of leprosy having been found in fish caviare."

EXPLOSIVE COUGH MIXTURE.

To the Editor of THE LANCET.

SIR,—Reverting to recent correspondence in THE LANCET relative to "An Explosive Cough Mixture," I have read with interest the annotation in your issue of March 26th relative to spirit of nitrous ether and impure gum in mixtures. However, I have learned that even without the nitrous spirit a mixture may be explosive if it contains mistura amygdalæ.

I recently had the pleasure of a visit from my old friend Sir Francis R. Cruise who spoke on this subject. He tells me that he formerly prescribed such a cough mixture, which he derived from the late Sir William Jenner. The formula was as follows: Tinct. camph. co., syrupi scillæ, āā ʒiii.; aeth. chlorici, ʒii.; ext. liq. glycyrrhizæ, ʒss.; potassæ chloratis, ℈ii.; mist. amygdalæ, ad ʒviii. A tablespoonful when cough is troublesome. Sir Francis Cruise adds that in many cases in his experience this mixture when kept in a warm room for a few days exploded—sometimes expelling the cork and at other times bursting the bottles.

In one case an eminent Church dignitary was rudely wakened from sleep by so violent an explosion that he feared an earthquake. On

lighting a candle he found it was only the bottle containing his cough mixture that had blown up! Another case ended more seriously. A lady had a bottle with similar contents corked in her hand when it exploded, and a fragment of glass opened the radial artery which had to be tied by operation under ether.

Needless to say, Sir Francis Cruise gave up *that* prescription, but found that if the mist. amygdalæ was omitted and another menstruum used, such as infusum lini, aqua chloroformi, &c., no explosion followed.

I am, Sir, yours faithfully,

Dublin, March 29th, 1910. NINIAN M. FALKINER.

THE NEW EXAMINATION HALL OF THE ROYAL COLLEGES OF PHYSICIANS AND SURGEONS.

A RECENT number of the *Building News* contained illustrations of the designs which gained the first two premiums awarded in the recent competition for the new "Conjoint" Examination Hall to be erected in Queen-square. Mr. T. E. Collcutt, F.R.I.B.A., who acted as assessor in the competition, awarded the first premium to Mr. Andrew N. Prentice, F.R.I.B.A., and the plan and elevation which he submitted are also published. The following description is given of the new buildings:—

> "The scheme is planned to form a compact block on the front of the site. The students enter on the basement level at the rear, near their cloakrooms, and do not confuse with the official business of the ground floor. The administrative portion of the buildings has been placed to the front of the site, so that callers can reach either of these rooms without mixing in the general circulation of students. The waiting-hall is placed at the back, in communication with both staircases. The entrance corridor is so arranged that these staircases can be reached from the main entrance without entering the waiting-hall when the *vivâ voce* students are there. The large examination halls have been placed along the front of site with the smaller examination halls, on a central axis with them. This allows the rooms to be easily supervised when they are used jointly. Externally, the building is designed to harmonise with the surroundings, and is treated in an early Georgian style adapted to modern requirements as to height. It is proposed to use red bricks with the lower storey, cornices, and window dressings, &c., in Portland stone. A little sculpture is introduced. It is proposed that the small figures in the frieze should carry instruments suggesting the nature of the building, and should be in low relief."

TANNIN IN TEA.

To the Editor of THE LANCET.

SIR,—Old superstitions seem to die hard. I see in THE LANCET of March 26th an account of a new kind of teapot, designed to exclude tannin from the infusion. The object of doing so is not very clear. I am aware there is a prejudice against tannin in tea, though why I could never ascertain. Personally I prefer tea with a fair amount of tannin, and I think the taste of most people is the same, though they fancy it is more wholesome without it. I have never known tannin to do any harm to man, woman, or child. On the other hand, it is a useful astringent and antiseptic to the mucous membrane. We take tannin lozenges, we paint the throat with glycerine of tannin, we take tincture or infusion of cinchona and port wine (some of us) without protest. It is only when it happens to be in tea that we fancy tannin is injurious. Surely it is the theine, not the tannin, that causes insomnia and other nerve symptoms in tea-drinkers. There is a firm now selling coffee from which all the caffeine has been extracted. I presume they will soon do the same for tea. If they do I hope they will at least leave us the tannin. Tea without theine and without tannin will be rather poor stuff, undistinguishable to the uninitiated from unadulterated or slightly shaded hot water.

I am, Sir, yours faithfully,

London, S.W., March 28th, 1910. J. FOSTER PALMER.

STANDARDISATION OF BREAD.

THE Bread and Food Reform League has published another pamphlet on the "Standardisation of Bread," again urging the necessity of securing purity from adulteration and abolition of injurious chemical processes in preparing flour and bread, and the establishment of a standard for what is sold as household bread not only with regard to flesh-forming materials but also with respect to mineral substances. An analysis of flours from several districts made for the league by Mr. C. G. Moor, F.I.C., is given, showing a great deficiency of these important substances, which were considerably below the recognised standard for ordinary white flour, and it is stated that the old-fashioned household flour, advocated by the league, containing 80 per cent. of wheat, retaining the germ and the semolina, has 55 per cent. more mineral matter. Wholemeal is said to have 247 per cent. more, but as the old-fashioned household flour has a small amount of woody fibre and produces cream-coloured, well-aerated bread it may meet with approval from those who now object to brown bread. The council of the league directs attention to the fact, to which we have given publicity, that the brown bread, sometimes called "black bread," used in Germany is found to be more nourishing and sustaining than over-refined white bread. As a supply of pure bread, containing a sufficient supply of all the elements of nutrition, is of vital national importance, the Council of the Bread and Food Reform League urges the necessity of making every effort to raise the standard of bread so that it may become a more complete and healthier food for all classes, and better deserve the title of the staff of life. The address of the honorary secretary of the Bread and Food Reform League is 5, Clement's Inn, Strand, London, W.C.

TERATOLOGY IN ITALY.

FROM no country could Geoffroy St. Hilaire's classic treatise on monstrous births be more richly supplemented than from Italy—except, perhaps, from Spain, which (according to the Maestro Rossini) has earned the gratitude of all Italians by saving their nationality from the reproach of being the most backward in Europe. Ignorance, superstition, and life under hard conditions such as these countries are still subjected to seem to favour what the older teratologists used to call "lusus Naturae" (Nature's freaks or practical jokes). The latest of these (a rather gruesome one) is reported from Avellino, some 50 miles south-east of Naples, where a peasant woman, Bianca Fierro by name, aged 25 years, gave birth to a female "creatura" on the evening of March 22nd. This creature, the outcome, it seems, of "illicit amours," could, according to the medical reporter, "give points to Victor Hugo's Quasimodo." Its mouth was that of a reptile, portentously wide; the nose bifurcated; the cranium compressed; the ears of great size; one eye placed below one of the ears, the other in the middle of the forehead; one leg attached to the immediate neighbourhood of the umbilicus, and the other below the spine "in senso inverso" (turned the wrong way). The "creatura" lived for some 24 hours, emitting "grida stranissime" (very strange cries), and, naturally enough, "ha vivamente impressionato questo popolino" (made a vivid impression on the population of Avellino). Its destination, of course, is not the "campo santi," but the local museum—if not that of the Neapolitan school, from one of which an interesting paper on the phenomenon may shortly be expected.

ALCOHOLISM IN RUSSIA.

THE *Novoe Vremya* recently welcomed a proposal of the Minister of Finance (at the instigation of Professor Bechterieff) to allot 100,000 roubles (£10,625) to found a clinic for alcoholics in connexion with the Psycho-Neurological Institute. Hitherto practically nothing had been done in Russia to counteract the drink habit, which is said to be responsible for 200,000 deaths in the Empire each year. The charts shown at the recent exhibition at the institute in question displayed the curve of the progress of "paralysis of the brain" in the community, and this was closely proportionate to the increasing consumption of drink per head of the population. Phthisis, moreover, which destroys 700,000 people in the year, very often has its origin in alcoholism. M. Tchelischeff, a member of the Duma, said in a speech that only 40 per cent. of the recruits called up in 1909 were fit for military service, and he had a letter from one officer saying that of all the recruits that came before him at the last requisition only 8 per cent. were not drinkers, whilst 30 per cent. were in such bad health as to pass into the Reserve inside three months, whereas 20 years ago only from 4 to 8 per cent. were so released in that period of time. Only a few private institutions are available for the treatment of alcoholism, and their charges are very high. It cannot be wondered at that many seek refuge in quack establishments in hope of cure. Self-taught hypnotists without any medical knowledge perform their manipulations over whole parties of patients at a time. It is said of one such St. Petersburg quack that he causes parties of 15 persons of both sexes to lie down side by side, then performs his "passes," and leaving them there two hours goes into another room to repeat the performance over another party. The proposed new clinic will include hypnotic suggestion in its treatment, and the removal of bad cases after treatment to a sanatorium for dipsomaniacs is contemplated.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

THURSDAY.

OBSTETRICAL AND GYNÆCOLOGICAL SECTION (Hon. Secretaries—W. J. Gow, G. F. Blacker) at 15, Cavendish-square, W.: at 7.45 P.M.

Specimens:

Dr. A. E. Giles: Large Fibroid of Cervix.

Paper:

Dr. Henry Jellett: The Place of Cæsarean Section in the Treatment of Placenta Prævia.

FRIDAY.

ELECTRO-THERAPEUTICAL SECTION (Hon. Secretaries—Reginald Morton, G. Harrison Orton) at 15, Cavendish-square, W.: at 8.30 P.M.

Paper:

Dr. Howard Pirie: The Disappearance of Enlarged Glands in Lymphadenoma under Treatment by X Rays.

Discussion:

The Relative Value of the Various Types of High Tension Transformers used for the Production of X Rays (opened by Dr. Reginald Morton).

Demonstrations:

Dr. Howard Pirie: A Pocket Stereoscope for Use with X Ray Negatives.

Mr. A. J. H. Iles: A New Simple Stereoscope.

MEDICAL SOCIETY OF LONDON, 11, Chandos-street, Cavendish-square, W.

MONDAY.—8 P.M., Clinical Meeting.

HUNTERIAN SOCIETY, London Institution, Finsbury-circus, E.C.

WEDNESDAY.—8.30 P.M., Discussion on Vaccine Therapy (introduced by Dr. H. White).

UNITED SERVICES MEDICAL SOCIETY, Royal Army Medical College, S.W.

WEDNESDAY.—8.30 P.M., Lieut.-Colonel H. E. Deane (R.), R.A.M.C.: Records of Pulse-rates after Exercises of Various Kinds in Trained and Untrained People (illustrated by sphygmograms).

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.

THURSDAY.—8.30 P.M., Dr. L. Williams: Surgeons, some Mortals, and the Climacteric.—Dr. E. I. Spriggs: The Treatment of Indigestion.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. K. Fowler: The Diagnosis, Prognosis, and Treatment of Pneumonia.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

FRIDAY.—3.45 P.M., Lecture:—Dr. Abercrombie: Clinical Cases.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (11th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.).

TUESDAY (12th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College 2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Central London Throat and Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

WEDNESDAY (13th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan 9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (14th).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. FRIDAY (15th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.) Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor 9 A.M., Major, 2 P.M.).

SATURDAY (16th).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND Co., 51, Fifth Avenue, New York, U.S.A.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnières, Paris.

The Goulstonian Lectures

ON

A CONTRIBUTION TO THE LOCALISATION OF CEREBRAL FUNCTION, BASED ON THE CLINICO-PATHOLOGICAL STUDY OF MENTAL DISEASE.

Delivered before the Royal College of Physicians of London on March 1st, 3rd, and 8th, 1910,

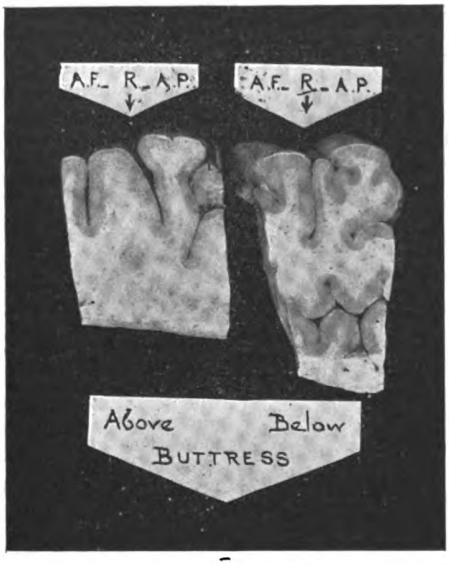
BY JOSEPH SHAW BOLTON, M.D. LOND., F.R.C.P. LOND.,

FELLOW OF UNIVERSITY COLLEGE, LONDON; SENIOR ASSISTANT MEDICAL OFFICER, LANCASTER COUNTY ASYLUM, RAINHILL, ETC.

LECTURE III.[1]

Delivered on March 8th.

MR. PRESIDENT AND GENTLEMEN,—Having completed the description of my observations and deductions with regard to the structure and functions of the visuo-sensory (or sample sensory projection), the visuo-psychic (or sample special associative), and the prefrontal (or higher voluntary associative) regions of the cortex, I now pass on to certain observations with regard to the structure and functions of the final type of cortex with which I propose to deal—namely, the pre-Rolandic or psychomotor.



STRUCTURE AND FUNCTIONS OF THE PRE-ROLANDIC CORTEX.

It is unnecessary for my purpose to describe in detail the great controversy which raged for so many years as to whether this region possessed purely motor or sensori-motor functions. I shall merely remind you of how the histological researches of Bevan Lewis and Henry Clarke, which as long ago as 1878 resulted in the delineation of the Betz cell area, were forgotten in the heat of the controversy until 1901, when, through the experimental work of Sherrington and Grünbaum, followed by the histological researches of Campbell and of Brodmann, they finally received belated recognition.

Since that time the majority of observers have credited the precentral gyrus with motor and the postcentral with sensory functions; and this opinion received confirmation, so far at any rate as the experimental method can be regarded as capable of affording it, from the researches of Oskar Vogt, who in 1906 published a paper describing the results of stimulation and extirpation of the precentral and postcentral gyri. In brief, Vogt concluded that palsy without ataxy followed destruction of the precentral gyrus, and ataxy, but no palsy, resulted from destruction of the postcentral gyrus. Last year, however, in the Linacre lecture, Sir Victor Horsley described what he regards as a crucial test case and reiterated his conviction that the so-called motor area is really sensori-motor. From this patient, who suffered from athetoid movements of the left hand followed by violent convulsive movements of the whole upper limb, Horsley removed by operation the portion of pre-Rolandic cortex which, as the result of stimulation, he concluded to constitute the whole of the arm area. He carefully describes the immediate results, which were partly motor and partly sensory, and the remote results (a year later), which consisted of permanent absence of spasmodic movements, partial recovery of voluntary movement of the left upper limb, and considerable recovery from the sensory disability. On this case Horsley bases his contention that the precentral gyrus is sensori-motor in function.

The evidence which I purpose laying before you points to very different conclusions regarding the functions of this region of the cortex, and, unless these conclusions are correct, the whole of the observations and deductions contained in my two previous lectures falls to the ground. I would, therefore, submit that in my opinion the experimental method, even in the hands of so renowned an operator as Horsley, cannot be regarded as trustworthy. On purely theoretical grounds, it might well be doubted whether a gyrus of considerable size could be removed without any disturbance of the functions of the immediately adjacent gyrus resulting, but in this instance anatomical reasons exist which appear to me to render such an operation a practical impossibility. To indicate these I will now show on the screen naked-eye sections through the fissure of Rolando which are situated above and below the buttress, and thus indicate the arrangement of the neighbouring gyri in both these positions. I introduce the two sections in order to avoid the possible criticism that the arm area is not included, since this area was placed above the buttress as the result of the earlier stimulation experiments on man, although it is now considered to lie below this annectant. In the first section, which is above the buttress, is seen the extremely narrow neck of the gyrus postcentralis, and the nearness of this to the site of operation. In the next section, which is below the buttress, the same point is equally clearly visible, as is also the relative nearness of the gyri of the parietal operculum to the seat of operation. Apart entirely from the intimate structural and functional associations of the pre- and post-central gyri, these photographs in my opinion indicate the probability, I may even say the certainty, that removal of the precentral gyrus, however carefully performed, will result in functional if not also in actual structural interference with the fibres passing to and from the postcentral gyrus.

FIG. 19.

Naked eye sections across the central convolutions. The left hand section is above the buttress, and the right hand section is below this annectant. R. = furrow of Rolando. A.F. = precentral or ascending frontal gyrus. A.P. = postcentral or ascending parietal gyrus. Both sections show the extremely narrow neck of the postcentral gyrus, and the right hand one also indicates the proximity of the gyri of the parietal operculum. The figure demonstrates that removal by operation of the precentral gyrus, however, skilfully performed, must necessarily result in functional, and probably also in structural, damage to the fibres entering the neck of the postcentral gyrus.

LAMINATION OF THE PRECENTRAL GYRUS.

I now pass on to the consideration of the structure of the precentral gyrus, from the aspect of cell lamination. In the case of this region I have not resorted to the micrometric method, partly because the structural conditions preclude the possibility of obtaining a series of measurements from the four situations I am accustomed to select, and partly because the practical absence of a middle cell lamina or granule layer renders measurement of this untrustworthy even if possible. I therefore propose to illustrate my point, not by series of measurements from human subjects, but by exhibiting certain mammalian cortices, which show the depths of the various laminæ in a cruder but equally satisfactory manner. As a preliminary remark, I would state that the lamination of the precentral gyrus, though to the inexperienced eye indefinite, is of the usual general type, consisting of an outer fibre or superficial lamina, an outer cell

[1] Lectures I. and II. were published in THE LANCET of April 2nd (p. 905) and 9th (p. 980), 1910.

or pyramidal lamina, a middle cell or granule lamina, an inner fibre lamina or inner line of Baillarger, which here contains the Betz cells, and an inner cell or polymorphic lamina.

The photographs are all of the same magnification and strictly comparable. Fig. 20 is taken from the Betz cell region of the dog. The laminæ of which it is composed are the superficial (I.), the pyramidal (II.), the indefinite granule (III.), the inner line of Baillarger with certain Betz cells (IV.), and the polymorphic lamina (V.). I wish particularly to draw your attention to the fact that the second lamina or pyramidal layer (0·45 millimetre) is in depth about one-third of the combined depths of the laminæ below it (1·18 millimetres). I would also point out the large size and generally embryonic condition of the cells in all the laminæ.

Fig. 21 illustrates the precentral cortex of the rhesus. The laminæ of which it is composed are the outer fibre (I.), the pyramidal (II.), the thin granule (III.), the inner line of Baillarger with certain Betz cells (IV.), and the polymorphic lamina (V). I would particularly ask you to note that the depth of the pyramidal lamina (0·91 millimetre) is practically equal to the conjoined depths of the laminæ below it (0·90 millimetre), and also that the individual cells of all the laminæ are smaller and more numerous than in the dog, and are also better made and relatively more widely separated from one another.

Fig. 22 shows the cortex of the human precentral gyrus. The laminæ of which it is composed are the outer fibre lamina (I.), the second or pyramidal lamina (II.), the very indefinite granule lamina (III.), the fourth lamina or inner line of Baillarger with certain Betz cells (IV.), and the fifth or polymorphic lamina (V.). I would draw your attention to the fact that the second or pyramidal lamina (1·24 millimetres) is in depth four-thirds of the conjoined depths of the laminæ below it (0·92 millimetre), and also to the detail that the individual cells are very well made and are more widely separated from one another than in the rhesus. A comparison of Figs. 20 to 22 shows that the essential differences between the cortices consist in a very marked and progressive improvement in the development of the individual cells in all the laminæ, but, particularly, in the degree of evolution of L.II, the pyramidal lamina, of the several cases. L.II, the outer cell or pyramidal lamina, which is of psychic, associative, and educative significance, is thus the prominent feature of the precentral cortex of man. L.III, the granule or receptive lamina, is reduced to a minimal depth in all the cortices. L.IV & V, which are of organic and instinctive significance, are similar in type in man and the rhesus, and in the dog their depth is somewhat greater and their cells are more embryonic in structure.

CONCLUSIONS FROM STUDY OF LAMINATION.

A study of these cortices leads to the following conclusions. The outer cell lamina or pyramidal layer of the dog is one-half of the depth of that of the rhesus, which again is three-fourths of that of the human subject. The middle cell lamina is so deficient in depth and in content as to be practically invisible, except to the experienced observer. The combined depth of the lower laminæ is practically the same in the rhesus and man, and is one-fourth deeper in the dog than in the others. The ratio of the depth of the second or pyramidal lamina to that of the three lower laminæ is in the dog about one-third, in the rhesus 1/1, and in man 4/3. In man, therefore, the precentral ratio is as high as, or slightly higher than, in the prefrontal region, in which the general average measurements give an average ratio of about 11/10.

As a very rough analogy, the pyramidal lamina of the dog may be compared with that of a still-born infant, and the pyramidal lamina of the rhesus with that of an imbecile.

Finally, in passing from the dog to the rhesus and from the rhesus to man there is a very marked and progressive improvement in the development of the individual cells in all the laminæ, which general improvement, however, pales before the great difference which exists in the three cortices with regard to the evolution both in depth and in content of the outer cell or pyramidal lamina.

In view of the conclusions which I expressed in the last lecture with regard to the functions of the primary cell laminæ of the cortex the deduction is evident. The outer cell or pyramidal lamina, which is of psychic, associative, and educative significance, is the prominent feature of the precentral cortex of man. The granule or receptive lamina is reduced to a minimum depth in all the cortices. The fourth and fifth laminæ, which are of organic and instinctive significance, are of the same depth and general type in man and in the rhesus, and in the dog their conjoined depth is one-fourth greater and their individual cells are more embryonic in structure. *The obvious conclusion, therefore, is that in man the psychic, associative, and educative functions of the precentral gyrus are paramount, that in all three the receptive functions are minimal or non-existent, and that the organic and instinctive activities are approximately on the same level in all the three.* When this conclusion is regarded in association with the well-known truth that the particular type of cortex under consideration increases in area and differentiation, during the ascent of the mammalian scale, not according to muscular bulk, but according to the degree of motor educability exhibited by the several parts of the body, the further conclusion that the Betz cells merely serve as a relatively simple motor mechanism, and that motor educability must have its structural seat in the second or pyramidal lamina, is inevitable. That the Betz cells serve as the origin of the pyramidal tracts has long been believed. It is, in fact, many years now since I noted well-developed Betz cells in the cortex of a fœtus of six months, and therefore took for granted that they served as the origin of these tracts. The truth of this presumption has recently been finally proved by Holmes and Page May. Further, it has long been known to physiologists that whilst the pyramidal tracts normally conduct voluntary efferent impulses, such impulses in the functional absence of these tracts can still find passage. For example, a hemisection of the spinal cord of a dog followed by a higher hemisection on the opposite side, and this again followed by a still higher hemisection, this time on the original side, results in at least a very considerable return of power over both lower limbs. It may thus be regarded as proved that the Betz cells serve, not as the psychomotor cortical mechanism, but simply as a subservient mechanism for the direct transmission of voluntary impulses to the lower motor centres. I may add, as a necessary consequence to this conclusion, that the Betz cell distribution need no longer therefore be regarded as indicative of the limits of the cortical zone concerned with the evolution of those associational processes which, when translated by the agency of the lower motor centres into muscular movements, constitute the sole objective indications of cerebral activity. If, as I consider proved, reliance can be placed on the results of the histological investigations of the past decade, the educable psychomotor cortex, with little modification, extends over almost or quite the posterior half of the frontal lobe, where it grades, through cortex of an intermediate type, into that of the prefrontal region.

Having, as I hope, sufficiently indicated my reasons for regarding the precentral cortical zone as psychomotor, rather than motor or sensori-motor, in function, I will exhibit, as a histological contrast, a slide prepared from an illustration published by Gordon Holmes, in order to show the well-defined middle cell lamina or granule layer which exists in the postcentral gyrus. The proportion which the depth of this lamina bears to the total depth of the cortex—namely, about one-eighth—is to me, at any rate, sufficient in itself almost to prove that this cortex belongs to a sensory projection sphere; in other words, to indicate with great probability the performance of sensory receptive functions by the postcentral gyrus.

LOCALISATION OF CEREBRAL FUNCTION.

The general trend of the results of the recent histological survey of the cerebral cortex, which followed the enunciation by Flechsig of his doctrine of centres of projection and centres of association, and which has culminated in the elaborately detailed descriptions of Brodmann, has, to say the least, been highly suggestive of the existence of a definite correlation between histological structure and functional significance; and it is probable that the histological method, without entirely replacing the experimental, will in the future be still more fruitful in this direction. In the personal investigations which I have described I have endeavoured, by the employment of subnormal and pathological

FIG. 20.

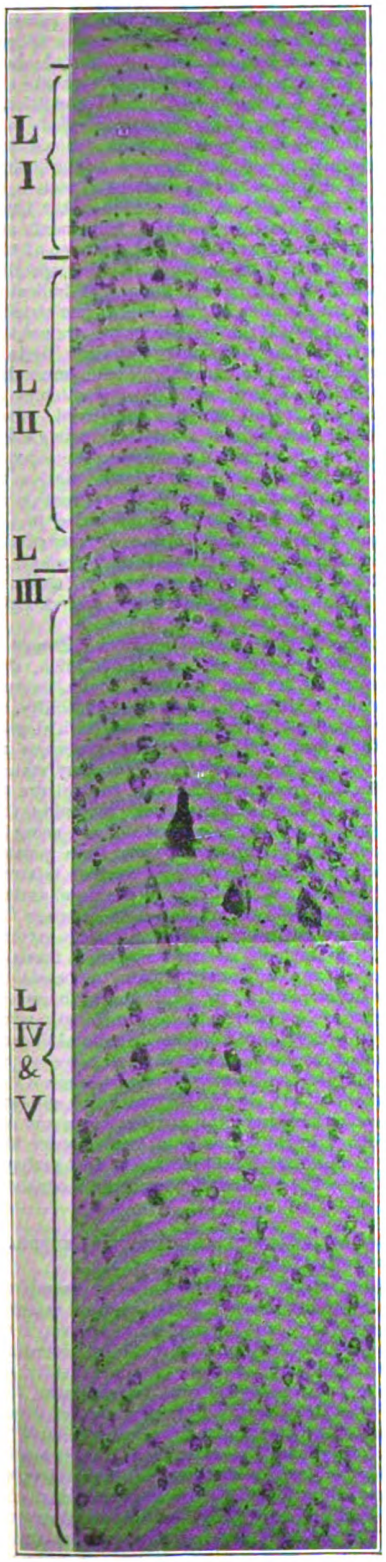


FIG. 21.

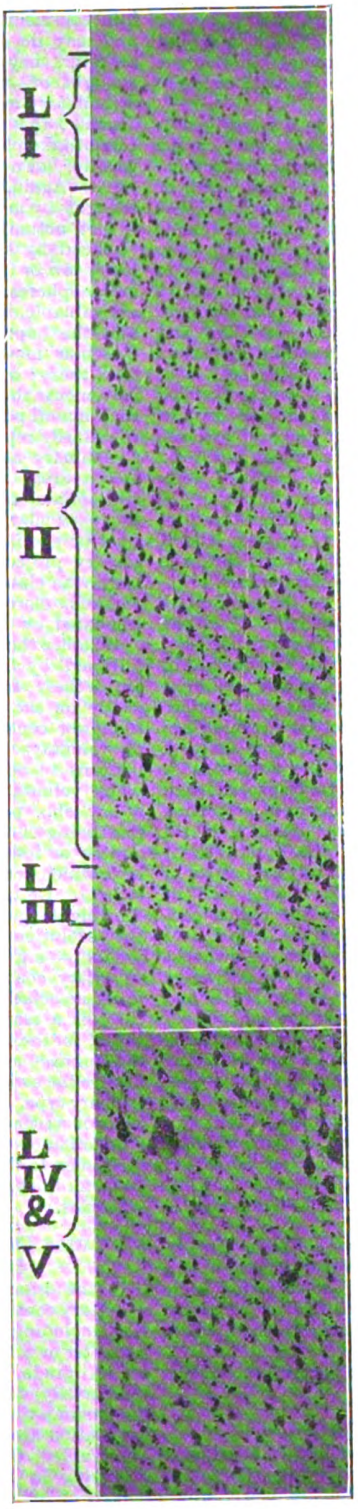

FIG. 22.

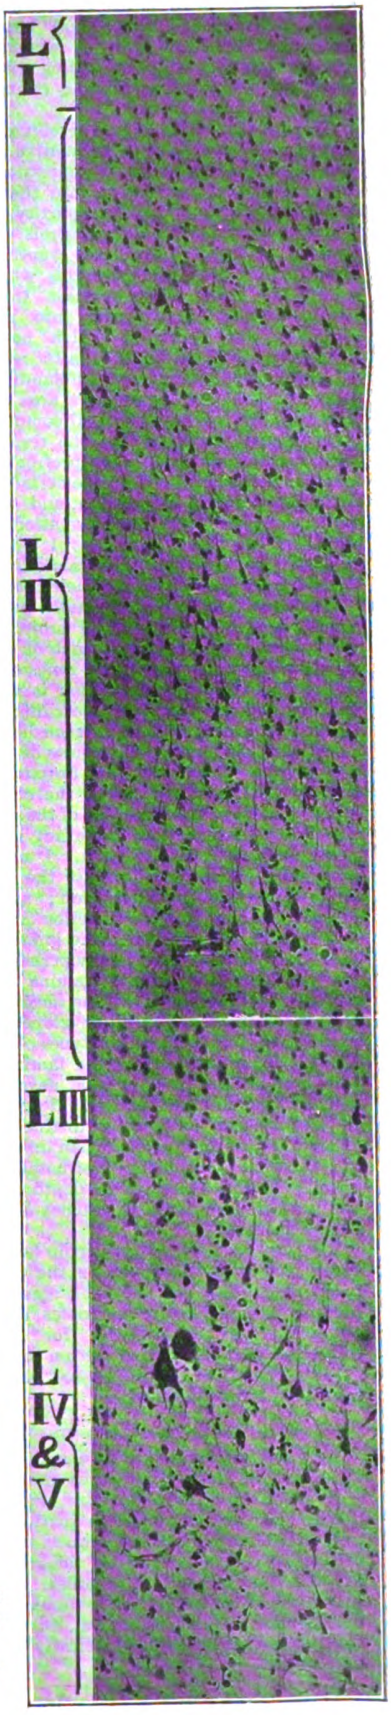

FIG. 20.—Cortex of the Betz-cell area of the DOG. 109 diameters. L.I = outer fibre or superficial lamina. L.II = outer cell or pyramidal lamina. L.III = the indistinct middle cell or granule lamina. L.IV & V = the inner fibre lamina or inner line of Baillarger containing Betz cells, and the polymorphic lamina. The depth of L.II is about one-third of the conjoined depths of L.III–V.

FIG. 21.—Cortex of the Betz-cell area of the RHESUS. 109 diameters. L.I to L.V as in Fig. 20.

FIG. 22.—Cortex of the Betz-cell area of MAN. 109 diameters. The full description is in the text.

material, to obtain proof of the functional significance of certain of the histologically differentiated regions of the cortex. Such proof as I have obtained leads me to adopt, as a partially proved provisional hypothesis, the following scheme of the localisation of cerebral function. I do not claim originality, since in dealing with cerebral function one needs to select rather than to enunciate opinions owing to the multitude of these.

I would regard the human cerebrum not as a sensori-motor but as an intermediate or associative ganglion, which on the one hand receives sensorial impressions and elaborates them by processes of association into the physical equivalents of psychic products of high complexity, and which on the other hand to a variable extent controls, selects, and coördinates certain of these equivalents, eventually transforming them into further physical complexes whose function is to set in action the lower motor centres. On this functional basis I would divide the cerebrum into pre- and post-Rolandic portions, the former of which possesses controlling and executive functions, and the latter receptive and elaboratory. I would subdivide the pre-Rolandic part, or frontal lobe, into a posterior or psychomotor area which is concerned with the evolution of such physical complexes as are necessary to give external expression to the results of cerebral association, and into an anterior or prefrontal area which is able to control, select, and coördinate certain of the results of post-Rolandic cerebral association, and to either allow these to undergo psychomotor transformation or to inhibit this process. Both these functions I regard as proved, and I consider the outer cell or pyramidal lamina of the cortex to be at least the chief seat of their actual performance.

The cortex of the post-Rolandic portion of the cerebrum I would regard as consisting of projection areas, of which the visuo-sensory area is a type, each of which is surrounded by, or possesses in its proximity, zones of special association, of which the visuo-psychic region is a type, which zones are hall-marked in function according to their appropriate projection areas; and of intermediate cortex in which are fused and elaborated the results of the special processes of association. I consider the functions of the visuo-sensory and visuo-psychic regions of the cortex to be proved, and, from homology, the functions of the other areas of projection and special association, the exact location of which is still probable rather than certain. I regard the outer cell or pyramidal lamina as at least the chief physical basis of these processes of association; and the middle cell or granule lamina of the projection areas as the region concerned with the reception and immediate transformation of sensorial impressions. I may perhaps here remind you that the middle cell or granule lamina attains to its maximum degree of development in the sensory projection areas, and that it continues to be well developed in the special zones of association. In both these types of cortex there is no clear line of demarcation from the laminæ above and below it. The granule lamina is of good development in the posterior region of general association, and also in the prefrontal area, in which latter it is more distinctly separated from the laminæ above and below it than in any region with which I am familiar. From the prefrontal region backwards the granule lamina decreases in depth and distinctness until in the psychomotor area it reaches a minimal depth and is barely discernible.

The inner cell or polymorphic lamina, as I have already stated, has been shown to be the prominent lamina in the lower mammalia, and must be regarded as subserving such organic and instinctive activities as are not acquired by education. It is probable, for reasons which I have indicated, that this is its function in man.

[The nature of language and the language mechanism were then briefly dealt with.]

LANGUAGE AND ITS MECHANISM.

By these few remarks I have endeavoured to indicate and illustrate the fact that words are merely symbols which possess different grades of value, and which are meaningless unless they are employed to incite the occurrence of such processes of cerebral association as are necessary to awaken the various sensori-memorial images of which such words are but the symbols. In order, therefore, that language may possess meaning, there necessarily occurs, during the employment of its mechanism, an active associational participation on the part of practically the whole mantle of the cerebrum.

As a preliminary to the consideration of the manner in which the language mechanism is voluntarily employed, I would remark that words, in my opinion, invariably arise into consciousness through the activity of sensory spheres, and may do so through that of any one of these. When, however, they are voluntarily and silently reproduced—i.e., thought of—words are invariably awakened through the articulatory-motor word centre under normal conditions. Further, this reproduction requires a muscular effort, and cannot take place without a definite attempt at articulation, usually, but not necessarily, accompanied by a slight expiration. Again, words cannot be voluntarily repeated in thought by means of the cheirographic centre if the hand is not actually moved, unless such hand movements are replaced by slight movements of the head, or even of the lower jaw or the eyes, through the agency of their respective motor spheres. Such observations as I have just indicated are valuable, because they render it probable, if not certain, that the important factors in the reproduction are not the muscular movements, but the sensorial impulses derived from these; otherwise there is no reason why such muscular movements should not be imagined, without any attempt at their actual performance. I thus consider that words, when voluntarily reproduced, are invariably awakened through the preliminary action of the prefrontal region on the psychomotor area, activity of which results in stimulation of appropriate neuron-complexes subserving the evocation of the particular sensori-memorial images which arise in the zone of special association attached at one or more of the sensory projection spheres. This view, I may remark, is merely an elaboration of that long ago advanced by Hughlings Jackson, more recently supported by Stricker, and strongly combated by Bastian.

Whether the arousing of such sensori-memorial images is followed by further processes of cerebral association, and what these further processes are if they occur, depend partly on the general condition, as regards excitability, of the lower centres of association and partly on such degree of voluntary guidance and control of these processes as happens to be exercised. For example, in dreamy states, when voluntary selection, coördination, and control are at a low ebb, processes of lower association, involving the awakening of all kinds of sensori-memorial images, occur in a more or less riotous manner according to certain general laws which are well known and need not be further referred to here. On the other hand, as an extreme example, during the voluntary employment of written or spoken language for the evolution and reproduction of the highest psychic products—e.g., the production of an abstruse thesis—voluntary control over, and guidance of, the processes of lower association are paramount. In such a case, however, there is a tendency, which requires to be continually combated, for the cerebral processes to keep to the general lines of the language mechanism, to the exclusion of such processes as involve the evocation of visual sensori-memorial images of the ordinary type. In other words, during the voluntary employment of written or spoken language for the evolution and reproduction of abstract thought, there is a tendency for the performer to become unintelligible to others, and perhaps even to himself, unless he continually reverts to concrete examples.

DEFECTIVE CONTROL OF PROCESSES OF LOWER CEREBRAL ASSOCIATION IN MENTAL DISEASE.

In the insane, as I shall now illustrate by examples, voluntary control over the processes of lower cerebral association, including the activity of the language mechanism, is to a greater or a lesser extent defective. In amentia, according to its grade, such voluntary control is permanently or temporarily defective. In many of the lowest types the mammalian tendency to sleep, unless the processes of lower association are stimulated by sensorial or organic stimuli, is observable. On the other hand, in attacks of simple mania occurring in the higher grades of amentia, the prefrontal centre of higher control is in functional abeyance, and the cerebrum acts as an uncontrolled sensori-psychomotor machine. Instead of, as normally happens, but a small selected number of the ever-entering stream of afferent impressions being noticed, almost every visual and auditory stimulus which arrives at the cortex is accepted. Processes of cerebral association incited by these occur pell-mell and find motor expression in emotional disturbance, rapid movements, and a riotous display of words. It is impossible to obtain

more than the momentary attention of the sufferer. This condition of uncontrolled sensori-psychomotor activity may last for hours, days, or weeks, after which the patient becomes, at any rate for the time, sane.

Again, in dementia, according to its grade, voluntary control over the cerebral processes of lower association is permanently defective or absent. If this be defective and the centres of lower association be normal, the chief clinical features exhibited by the patient are a general hebetude and a lack of interest in his surroundings. If, however, aberrant states of the centres of lower association exist, certain additional symptoms, to which I shall refer later, are presented. Further, in the grosser grades of simple dementia no evidence whatever of the existence of cerebral activity may be exhibited or obtainable, and the patient is an inanimate object, unable even to feed himself or to attend to the calls of nature.

I will mention as a final example the numerous cases of premature dementia which exhibit strange motor phenomena, and which are commonly classed under the term "catatonia." I believe that these phenomena are due to the occurrence of a more or less extensive dissolution of the neurons of the psychomotor areas in certain subjects, usually juvenile, in whom the fundamental psychomotor neuron groupings are still imperfectly organised into relatively stable complexes. The pathological condition is thus, on the one hand, one of subevolution of function, and on the other, one of dissolution or involution, the tract of cortex involved being practically the whole frontal lobe.

Such motor phenomena resemble, in brief, those which would occur in a "Frankenstein-man" or "mechanical-model," in which certain parts were imperfectly fashioned; in which certain groupings of parts were imperfectly tested and not in proper running order; in which the higher mechanical complexes were imperfectly controlled and co-ordinated into series, and therefore tended to stop, to repeat action, or to go by fits and starts; and in which, owing largely to the existence of several sources of motive power (i.e., from the different organs of sensation), certain mechanical complexes tended to run independently in consequence of an imperfect general coördination of, and control over, the whole mechanism. The motor phenomena are thus varied, and are, on the whole, of a distinctly positive or a definitely negative nature; and repetition, wayward and grotesque action, &c., are common.

In chronic cases the phenomena are often still further complicated as regards an immediate explanation, but simplified as regards their actual exhibition, by a more or less extensive dissolution of neurons, which results in stereotyped motor remainders of former skilled accomplishments. These, occurring on the dissolution side of the scale, differ in character from the erratic, grotesque, repeated, mechanical-model-like, and often unskilled movements which occur on the subevolution side and are due to imperfect control and insufficient practice.

That this explanation is probably correct is indicated by the fact that in a series of chronic cases of premature dementia without motor phenomena 55 per cent. exhibited a moderate grade of dementia, whereas, in a series presenting motor phenomena, as many as 73 per cent. had attained a moderate grade of dementia. I may remark that this grade of dementia indicates the existence of intracranial morbid appearances of moderate intensity, these representing the usual final stage which cerebral dissolution reaches in the absence of marked degeneration of the cerebral arteries.

INDEPENDENT ACTIVITY OF LOWER CENTRES OF ASSOCIATION.

I now pass to the consideration of certain phenomena due to the independent activity of the lower centres of association. Words, as I have remarked, when voluntarily reproduced in thought, are awakened through the action of the prefrontal cortex on the psychomotor area, this commonly being followed by activity of one or more centres of special lower association, and often by that of the whole region of general lower association. Such are, therefore, regarded as normal products of thought of *personal* origin. The other normal, and in this case non-personal, mode of origin, which applies to all types of sensation, is, of course, that of sensorial stimulation.

A third mode of origin of words, and also of other varieties of sensori-memorial image, is, however, common in normal persons; and if the mode is not more common the results of it are, at any rate, more obtrusive in the subjects of mental disease. I refer to the spontaneous arising of words or other sensori-memorial images in the auditory or visual centres of lower association. From my experience of these phenomena in the subjects of mental disease I have no hesitation in classing all such as hallucinations, which hallucinations may or may not be distinguished by the subject from true auditory or visual sensations. A homologous phenomenon to such a hallucination may be observed during the stimulation of the psychomotor area of a monkey which has recovered from anæsthesia. Such an animal regards the movement, say of the arm, with great surprise and at once performs a voluntary and opposite movement, exactly as if the limb had been moved by an external agency. The resemblance between this response and the behaviour of a lunatic who is replying to "voices" is striking.

[These remarks were then illustrated by reference to "dreamy states" and dreams, and the subject of illusion in the sane was discussed. Illusion and hallucination in the insane were then dealt with, and were illustrated by reference to certain types of mental disease, from the aspects of high grade amentia on the one hand, and of recoverable mental confusion and the mental confusion of actively progressive cerebral dissolution on the other.]

ILLUSION AND HALLUCINATION.

It is thus evident that illusion and hallucination grade from, on the one hand, the simple false recognitions of the normal sane individual to, on the other, vivid associated memories which arise by processes of lower association in the absence of sensorial stimuli, and which, in the absence of control over these processes of cerebral association, may present such a resemblance to the psychic results of the recognition of sensorial stimuli as to be mistaken for these and projected externally. Normal illusions thus occupy one end of the series, and the purely psychic phenomena described as hallucinations occupy the other, the numerous intermediate types of illusion possessing greater associational and less sensorial components until pure hallucinatory phenomena are reached.

Such psychic phenomena may occur as the result of a pathological process which is of a temporary nature or which will result in neuronic dissolution; they frequently, however, occur in the absence of active pathological conditions of the cortical neurons. In the former case, particularly when the pathological process is widespread, considerable mental confusion exists, and illusions may occur in association with aberrant sensorial stimuli of any kind. It is usual, however, for visual illusions to predominate, because, in such patients, visual stimuli are as a rule the more numerous. In the latter case, in the absence of active pathological states of the cortical neurons, and in the consequent absence of mental confusion, the psychic phenomena as a rule occur at night, and are often precipitated by imperfect and aberrant auditory stimuli. The cause of this relative prominence of auditory psychic phenomena appears to be twofold. On the one hand, in at any rate most ordinary individuals, the usual channels for the reception and transmission of knowledge are hearing and speech, sight, except in the case of special psychic acquisitions, occupying a subordinate position. Further, the majority of persons think in words as spoken rather than in words as seen. On the other hand, at night, and particularly during sleep, the higher cerebral processes are dormant or at their lowest ebb, and in consequence the processes of lower association, if active, are uncontrolled. Again, fear or apprehensiveness is naturally greater at night, or in the dark, than it is by day; and hearing, which is then the only sense available, is therefore preternaturally acute. It is thus possible to give a simple psychological explanation of the prominence of auditory illusions and hallucinations in such types of case as high-grade amentia and non-progressive dementia.

It is, of course, impossible in this lecture to do more than refer in the briefest manner to those more common symptoms of mental disease the physical bases of which may be relegated without hesitation to the centres of lower association. I shall therefore make no reference to the subject of delusion in the sane and the insane, or to that interesting and allied question the recording of experience in a time-related manner. I have merely endeavoured, as far as the time at my disposal has permitted, to indicate, in more or less

general terms, the relationship which I think exists between the normal processes of lower cerebral association and those which occur in the insane. Whilst the linking together of such normal and abnormal processes of cerebral association cannot be regarded as evidence in favour of the particular partially proved provisional hypothesis of the cerebral functions which I have attempted to lay before you, such a comparison is nevertheless of interest in that it shows that the processes of cerebral association, whether of the sane or of the insane, are equally susceptible of explanation by means of it.

In conclusion, I would thank you for the patience with which you have listened to what must appear to you a most unsatisfactory and incomplete description of observations which are in themselves equally unsatisfactory and incomplete. Though I dare not hope that I have even partially convinced you of the truth of the conclusions at which I have arrived, I at least trust that I have been successful in my efforts to show that the specialty of psychiatry is as worthy of study as are other and more honoured branches of medicine.

Note.—I have already made full acknowledgments elsewhere of the permission I have received during the past 15 years to use the cases and material needed during my investigations. It is, however, necessary to add that I continue to obtain my new material, through the courtesy of Dr. J. Wiglesworth, at the Rainhill Asylum. I would here repeat my grateful thanks to Dr. G. A. Watson, the pathologist, and to Mr. F. J. Abram, the photographer, for their ever ready assistance.

ABSTRACT OF THE

Hunterian Lectures

ON

THE SURGERY OF THE LYMPHATIC SYSTEM.

Delivered at the Royal College of Surgeons of England on Feb. 23rd and 25th, 1910,

BY W. SAMPSON HANDLEY, M.S. LOND., F.R.C.S. ENG.,

HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND; ASSISTANT SURGEON TO THE MIDDLESEX HOSPITAL.

LECTURE II.[1]

Delivered on Feb. 25th.

MR. PRESIDENT, LADIES, AND GENTLEMEN,—The next of the local lymphatic œdemas which claims our attention is elephantiasis arabum. This affection sometimes, though very rarely, originates in temperate climes. But, if inclined to minimise its importance, we should obey the exhortation to think imperially, and remind ourselves that in parts of India, according to Sir Patrick Manson, one individual in 20 suffers from the disease, while in some of the South Pacific islands half the population are affected.

My own experience of elephantiasis is a small one, mainly restricted to cases originating in this country. It is therefore with some hesitation that I approach the subject and venture to criticise some of the conclusions of such a master of research as Sir Patrick Manson. In justification of my criticisms and suggestions I may, however, plead Sir Patrick Manson's own statement that the pathology of elephantiasis is still obscure. The following quotation from his work presents a general picture of the disease in its clinical aspect:—

> Elephantiasis begins with an attack of lymphangitis and erysipelatoid inflammation of the integuments. Constitutional symptoms are severe, setting in with a sharp and prolonged rigor, followed by high fever, which in the course of a day or two generally ends in profuse diaphoresis, and often in a sort of lymphous weeping from the implicated skin. The inflammatory effusion is only partially absorbed, and some thickening remains. These attacks occur at irregular intervals of weeks or months, each attack leaving the limb or scrotum rather larger than before, until, in the course of years, the skin and cellular tissue has become enormously and permanently hypertrophied, and an unwieldy mass, justifying its name—elephant leg—is formed.

The success of lymphangioplasty in cases of dropsical arm naturally excited my hopes of equal success in elephantiasis, and an opportunity of trying the method occurred in a case which was fully described in THE LANCET of Jan. 2nd, 1909. This case, which differed clinically in no respect from tropical elephantiasis, save in the absence of micro-filariæ from the blood, raised the question whether the filarial theory of tropical elephantiasis is the whole truth. It proved, so far as one case can prove anything in a world of fallacies, that chronic infection with the staphylococcus alone, in the absence of filariæ, may cause elephantiasis.

The occurrence of micrococci in tropical elephantiasis, or more strictly speaking in the attacks of tropical lymphangitis, which precede or accompany elephantiasis, has attracted the attention of certain French observers. Just after the detection of the micrococci in the foregoing case I made the acquaintance of the work of Dufougeré, who describes an organism which he calls the lymphococcus, as constantly present in tropical lymphangitis. Dufougeré believes that in the absence of the filaria tropical lymphangitis subsides without leading to elephantiasis. Nor, in his opinion, does filarial infection alone produce elephantiasis, but if an individual in whose blood micro-filariæ are circulating becomes infected also with the lymphococcus through some wound or abrasion, the filariæ are killed and their dead bodies accumulate in the lymphatic glands and vessels, producing the obstruction which leads to elephantiasis. Dufougeré found the lymphococcus in three cases of acute lymphangitis, in two of which elephantiasis was already present.

Mr. A. G. R. Foulerton and Miss H. K. Whittingham state that "in the short description given of the lymphococcus there is nothing by which the organism could be distinguished from the staphylococcus."

In the year 1907 le Dantec described a diplococcus, which he called the dermococcus, as present in the subcutaneous tissues in elephantiasis in association with streptococci in the circulating blood. He believes that elephantiasis depends on the simultaneous presence of both organisms. Foulerton and Whittingham believe that these organisms are also in reality the *Staphylococcus albus*.

Can these results be ascribed to accidental contamination with skin organisms? Such a view is negatived, at any rate in my own case, by the opsonic observations, by the effects of vaccine treatment in preventing further attacks of lymphangitis, and by the fact that the cocci were observed in stained films of lymph taken from deep punctures. In my own opinion there is a good *primâ-facie* case for the belief that micrococci, derived originally from the skin, play an important part in the causation of elephantiasis. At any rate, further investigation is desirable, and it may be hoped that an expedition for the study of elephantiasis will add yet further laurels to the London School of Tropical Medicine.

My experience in the foregoing case showed that lymphangioplasty is not a cure for elephantiasis. It still seemed possible, however, that the operation might establish for itself a definite position in the treatment of patients who have sufficient leisure and intelligence to carry out prolonged after-treatment. But even this hope seems doomed to be disappointed, for in a second case of elephantiasis upon which I recently operated, though great temporary benefit resulted, within a few months of the operation the swelling of the leg has recurred, although the limb remains considerably softer than before operation. This patient carried out the after-treatment most carefully at home, and the recurrence of the swelling in her case shows to my mind that lymphangioplasty has failed to establish its position in the treatment of elephantiasis of the leg.

It would appear that in the lower extremity as contrasted for instance with the arm, the strenuous opposition of gravity nullifies the effects of the operation as soon as the limb is allowed to hang down for even a short period daily. The operation does, indeed, supply the channels which are missing, but, as I have always insisted, it does not provide a motive force. It is unable to fight against the full vertical pressure of gravity in the lower limb.

There is, however, another and more hopeful way in which the therapeutic problem of elephantiasis might be attacked, and that is by way of prevention or of arrest in an early stage. As I have shown there is a body of evidence that micrococci play an important and perhaps an essential part in its causation. And I would suggest, with the modesty

[1] Lecture I. was published in THE LANCET of April 9th, p. 977.

becoming my lack of tropical experience, and yet with the emphasis of strong belief, that elephantiasis can be arrested in its early stages by vaccine treatment directed against the micrococci which are present in many, if not all, cases of recurrent tropical lymphangitis—the forerunner of elephantiasis. In support of this belief I can quote my own case, the first case of elephantiasis, as far as I know, in which vaccine treatment has been employed. In this case no further febrile attacks have occurred since the vaccine treatment—a fact upon which the patient himself commented. If it proves to be possible to prepare a *Staphylococcus albus* vaccine which is a reliable safeguard against elephantiasis, the benefit to some tropical communities will be incalculable.

OTHER FORMS OF LYMPHATIC ŒDEMA.

My unfavourable conclusions with regard to lymphangioplasty in elephantiasis probably apply to all lymphatic œdemas of the lower limb, and I am thus absolved from dealing with them in detail. Nevertheless, they may be briefly referred to.

Under the heading of solid œdema dating from early life may be grouped a collection of probably heterogeneous cases in which there is a more or less solid œdema of one or both feet, extending a variable distance up the limb, tending, if uncontrolled, to become progressively worse, unaccompanied by visceral disease and not due to any traceable infection. The condition may be congenital, or may begin in infancy or childhood. In certain cases of this group the disease is hereditary, and has been given the name of Milroy's disease. Family histories of this type have been placed on record not only by Milroy but by Dr. H. D. Rolleston, Dr. Hope and Dr. H. S. French, Dr. G. A. Sutherland, and Dr. W. Bulloch. The disease is generally held to be caused by vaso-motor disturbance and to be closely related to angioneurotic œdema. One of Dr. Sutherland's patients had suffered from purpura and urticaria.

Cases may be met with which differ from Milroy's disease only in the absence of the hereditary element. Two such cases have been submitted to lymphangioplasty, one by Dr. T. P. zum Busch and one by myself, in both cases without benefit.

Cellulitis following a septic wound is sometimes followed by persistent brawny œdema, presumably due to associated lymphangitis and subsequent lymphatic obstruction. It is very doubtful whether such cases are suitable for lymphangioplasty, for phlebitis and venous obstruction are usually also present.

Although until recently I hoped that lymphangioplasty would be of benefit in puerperal white leg, I had always felt that the almost invariable presence of an element of venous obstruction made the question a very doubtful one. And although several such cases have been referred to me for the operation I have not found among them one which I considered favourable for the first essay. At the present time, and in view of the failure of the operation for elephantiasis of the leg, I am of opinion that lymphangioplasty is not applicable in such cases.

From a pathological point of view it is interesting to note that long-standing œdema from chronic tubal nephritis may produce in the legs many of the changes characteristic of elephantiasis, as in the following case:—

> The patient, a man aged 22 years, was admitted under my care with a view to the possibility of lymphangioplasty. When 9 years of age swelling of the ankles commenced and has progressively increased. The legs and feet are now much swollen, but the œdema still pits slightly on pressure. Two years ago the hands began to swell. The face also swells if his head is lowered, and the lumbar region as he lies in bed. Elevation of the part affected soon reduces the œdema. The urine contains 4·5 per cent. of albumin. The skin of the swollen legs shows the characteristic changes of elephantiasis, especially on the feet. Between the toes the skin is in a remarkable condition, being uniformly covered with somewhat pointed papillary eminences like an exceedingly coarse velvet.

My senior colleague, Dr. J. J. Pringle, sent to me last year a case which appears to show that tertiary syphilis may cause lymphatic œdema and all the changes characteristic of elephantiasis. The photograph which I show you absolves me from a detailed description of the case. The presence of foul gummatous ulcers upon the thickened skin deterred me from attempting operation, and present experience shows that it would have been useless.

THE OPERATIVE TREATMENT OF ASCITES.

I now come to the second main division of my subject—the application of conservative surgery to the treatment of ascites. The pioneer in this field of surgery is Mr. Rutherford Morison, who designed and carried out an operation for establishing in cases of portal obstruction a collateral circulation by way of the great omentum, which is artificially implanted in the subcutaneous abdominal tissues. While in some cases this operation has been strikingly successful, such cases form a small minority of the number in which the method has been applied. Thus Greenough, quoted by Jacobson and Rowlands, collected 105 cases of the operation, with a mortality of 29·5 per cent., and only 9 showed improvement after two years. The methods of internal drainage I am about to describe are certainly much safer than the Talma-Morison operation, and present experience indicates that they are much more efficient.

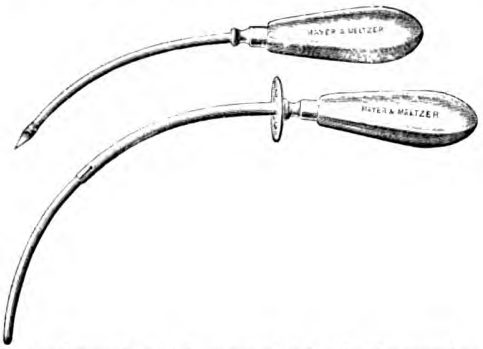
The treatment of ascites by the continuous drainage of the ascitic fluid into the tissues is a suggestion of my senior colleague, Dr. W. Essex Wynter, whose paper on this subject in the sixteenth volume of the *Archives of the Middlesex Hospital* is undoubtedly one of classical rank. It was my privilege to carry Dr. Wynter's scheme into successful practice, and subsequently to develop the same idea in association with the principles of capillary drainage by means of silk. I can best introduce the subject in Dr. Wynter's own words. He says:—

> The treatment of ascites by repeated paracentesis, commonly employed in hepatic cirrhosis, has proved unsatisfactory, inasmuch as in the majority of cases the fluid returns within a few days, and the patient is confined to bed or hospital for the remaining brief period of life, which seldom extends beyond two or three months.
>
> The steady downhill course and rapid loss of strength after paracentesis has been inauguarated indicate that the patient pays dearly for the relief of distension by the sacrifice of so much nutrient fluid, whose speedy replacement drains the blood and tissues and starves the kidneys.
>
> The objects aimed at by the method of subcutaneous drainage are:—1. The saving of nutrient material to the patient. 2. To ensure an adequate outflow of urine from the kidneys and a sufficient supply of fluid to the tissues by draining the stagnant pond of the peritoneal cavity. 3. To enable the patient to leave his bed and to maintain the circulation of the body fluids, especially in the portal and lymphatic systems, by means of exercise. 4. To relieve intra-abdominal tension, and thus promote lymphatic absorption and the establishment of a good collateral circulation.

To these objects I may add: 5. To diminish the intra-abdominal pressure by slow and gradual stages, thus avoiding the increased transudation of blood fluid and the possible hæmorrhage which may result from a sudden drop in the intra-abdominal pressure, such as occurs in the ordinary operation of tapping. Dr. Wynter adds that in view of the impaired vital resistance and deficient powers of repair found in ascitic patients a long operation, or one attended by much shock, is not to be thought of.

FEMORAL DRAINAGE.

Dr. Wynter considered the femoral canal as the best spot to choose for making the peritoneal opening, owing to its accessibility and low situation, the fluid being then allowed to flow into the subcutaneous tissues of the thigh, whence it is absorbed by the lymphatic vessels of the part. This operation may be spoken of as femoral drainage. The first case upon which it was performed was transferred to me for the purpose from Dr. Wynter's ward. This patient remains absolutely well up to the present date (January, 1910), a period of 2½ years.



TECHNIQUE OF THE OPERATION OF FEMORAL DRAINAGE.

The only difficulty in femoral drainage is that of finding the femoral canal. The tense abdomen bulges downwards over Scarpa's triangle, and the canal itself appears to be drawn up under Poupart's ligament by the tension of the peritoneal fluid, and perhaps by contraction of the peritoneum from chronic inflammation. I have found the following to be the best method. The special instruments required are a large-sized curved trocar and cannula, and a long blunt-pointed seeker, curved so as to pass through the cannula. Messrs. Mayer and Meltzer have made these instruments to my design. Tap the peritoneal cavity in the middle line about 2 inches above the pubes. Withdraw the trocar and insert the long seeker through the cannula, which it fits fairly closely. Next by a flap incision with its convexity directed outwards expose the region of the femoral ring. With the aid of the seeker find the situation of the femoral ring and push the seeker into it, thus making the femoral canal bulge into the floor of the femoral wound. With two pairs of artery forceps seize the peritoneum of the femoral canal on either side the point of the seeker, and with a pair of scissors

freely divide the peritoneum between the forceps. A certain amount of ascitic fluid escapes, but care should be taken not to empty the abdomen. Now introduce two sutures, one on either side of the opening, each taking up the peritoneum, and passing through Poupart's ligament. The sutures when tied serve to secure the patency of the new opening. Finally, suture the skin incision.

Among 5 cases of femoral drainage for ascites which have been operated upon at the Middlesex Hospital by my colleagues and myself 1 case must be excluded as due to carcinoma. Two of the remaining 4 cases were cured, while in the other 2 cases the course of the disease was unaffected, or influenced, if at all, in a favourable direction. These results in the case of a disease which is almost uniformly fatal are striking enough. It is probable that, whatever method of drainage be employed, there will be a not inconsiderable percentage of failure, for in some cases the ascitic fluid seems to be poured out in a cataract with which no drainage channels can be expected to cope. Thus in one of the cases 784 ounces of fluid collected within three days of paracentesis, a quantity which would appear beyond the carrying capacity of the absorptive vessels.

Effective as the operation of femoral drainage has proved itself, it has certain obvious defects. The new opening is

Trocar and cannula, with long curved seeker, for the operation of femoral drainage.

liable to be accidentally blocked by the descent into it of a piece of omentum, or by the adhesion of a loop of intestine over it. It may be closed within a short time by the natural processes of repair.

It occurred to Dr. Wynter that by the insertion in the linea alba of a flanged silver eyelet, with an opening a quarter of an inch in diameter, the peritoneal cavity might be placed in permanent communication with the subcutaneous tissues, at the cost of an operation hardly more severe than that of paracentesis. The skin is sutured over the eyelet, which now remains permanently in position. But this method proved unsatisfactory and the problem remained as before. It appeared to me that the question of providing a permanent outlet for the ascitic fluid might be solved by a modification of the operation of lymphangioplasty. Since the principle of the method was well tried and successful in the case of lymphatic œdema, I had no reason to doubt that the silk threads would act in the manner desired. The only doubt was whether they would form sufficiently capacious conduits to deal with such large quantities of fluid as are thrown out in ascites. In regard to the manner of their introduction, I have not been able to decide what is the best method. Many technical variations are possible, and the operation may not be standardised for some years to come.

In one case in which I decided to attempt internal drainage by means of silk threads the abdomen was opened by an incision in the left semilunar line and a large quantity of ascitic fluid escaped. The peritoneum generally was much congested, more especially the omentum, which oozed persistently when handled. Several ligatures had to be applied to check this bleeding. A stout needle threaded double with lymphangioplasty silk was now passed in and out in a series of loops through the peritoneum and subperitoneal tissues of the left iliac fossa external to the mesocolon. Short loops of the silk were left exposed within the peritoneal cavity, whence they could suck up fluid by capillary attraction. The process was repeated with two other threads. The four threads were conducted in the manner described to a point close to the anterior superior spine. With the aid of a long probe they were then thrust beneath the outer end of Poupart's ligament some way downwards into the subcutaneous tissues of the thigh. The abdominal wound was now closed in such a way that the sutures used provided additional permanent channels for the escape of fluid from the peritoneal cavity. A number of thick silk ligatures were employed, taking up the peritoneum and the muscular layers of the abdomen, but leaving out the skin. These were tied and the skin was then closed over them with a continuous superficial suture. At first the operation appeared to be a failure. The fluid re-collected and tapping became necessary 18 days after the operation, when 7½ pints were withdrawn. Two days subsequently the patient was discharged at her own request. She was icteric and grey looking, and appeared to have but a short time to live. I felt that if she could manage to get up and about gravity would assist the abdominal drainage, but even so I had abandoned hope of a favourable result. Her abdomen on discharge was 35¾ inches in circumference, and though not tense it contained a large amount of fluid, which appeared to be increasing rapidly. It was therefore a pleasant surprise when on July 28th she again presented herself looking much better. The abdomen though full was flaccid, and its circumference had decreased by more than 3 inches. Surrounding the region of the scar there was an œdematous area measuring about 8 by 4 inches, a clear proof that the silk used to suture the wound was acting in the way desired. On the other hand, so far from being œdematous, the thigh and leg were slightly smaller in circumference on the left than on the right side. It seemed as if the silk threads led into the thigh had proved useless. About Nov. 1st, 1909, a crop of subcutaneous gummata appeared on the left leg below the knee. About the same time the left leg began to swell. On Jan. 8th, 1910, when I again saw the patient, the left leg was markedly œdematous, measuring more than an inch more in circumference than the right one, and presenting numerous gummata, one of them ulcerated. The right leg was very slightly œdematous. The abdominal œdema had disappeared. The abdomen itself measured round the umbilicus 35½ inches, almost exactly the same as on her discharge eight months previously, but 3 inches more than on July 28th. It was so flaccid that no definite thrill could be obtained, though evidently a considerable amount of fluid was present. The liver could be definitely felt below the costal margin, although after the first tapping in the hospital it had been noted as atrophic. Her colour was good and her conjunctivæ clear and white, her tongue moist and clean, although she had not absolutely given up alcohol. She was free from abdominal pain and tenderness. She was getting about and living an ordinary life, although previously she seemed at death's door.

It is interesting to note that until seven months after the operation no proof was forthcoming of the functional efficiency of the silk threads led into the thigh. Œdema of the leg only appeared simultaneously with a local crop of gummata. It seems reasonable to infer, first, that without causing œdema drainage into the thigh had gone on ever since the operation; secondly, that if the absorptive power of the tissues is normal, and if the amount of fluid led into them is not excessive, the appearance of œdema is not to be expected; thirdly, that local lymph stasis favours the onset of gummata in the affected part; and fourthly, that the gummata in their turn interfere in some way with the return of lymph.

There are several points in which this case is open to criticism. It may, in the first place, be said that the case is one of syphilitic, not of alcoholic, ascites, and specific ascites is known to be amenable to specific remedies. But although the syphilitic element is undoubted, the alcoholic one is equally certain; and, so far as I know, no antisyphilitic remedies had been given until Jan. 10th, 1910, nine months after the operation. In view of these facts, and of the œdema of the region of the abdominal wound and of the left leg which were observed at different times, it can hardly be denied that the silk drainage operation determined her recovery.

The threads inserted in this case appear to be active and capacious channels while the patient is in the erect position and while the abdominal pressure is high. Under these conditions they appear capable of removing nearly half a pint of

fluid per diem. In bed, or after abdominal pressure has fallen to somewhere near the normal, their action seems to be sluggish. Thus they have failed to remove the considerable amount of fluid which may be present in the peritoneal cavity without distending it.

CANCER SURGERY AS A BRANCH OF LYMPHATIC SURGERY.

The whole field of the surgery of carcinoma belongs, in the strictest and most literal sense, to the ablational department of lymphatic surgery. When, for instance, an operation is performed for breast cancer, its object is not the extirpation of an organ but, as I have expressed it elsewhere, "the removal intact of the permeated area of the lymphatic system which surrounds the primary growth." This permeated area often extends far beyond the limits of the breast. At its periphery the lymphatic vessels are plugged by cancer cells, while the tissue spaces around are entirely free from cancerous infection. The removal of the infected area demands an accurate knowledge of lymphatic anatomy, and of the mode in which cancer spreads along the lymphatic vessels. To call such an operation "an amputation of the breast" is a dangerous abuse of words which is responsible for many failures in this field of surgery, a field apparently easy to traverse but in reality full of concealed pitfalls. Cancer surgery, then, is essentially a study in the extirpation of a diseased lymphatic area. Such a statement may appear to rest on too narrow a basis of evidence, for the theory of lymphatic permeation which I brought forward in 1904 has only been proved in the case of cancer of the breast and of melanotic sarcoma.

Some years ago I made repeated attempts to demonstrate permeation in the neighbourhood of abdominal cancers, using methods which I have found effective in the case of mammary cancer. These attempts, and similar ones made by at least two other investigators, ended in failure, owing to the difficulty of distinguishing cancerous from normal cells under the microscope.

Owing to the tendency of abdominal cancers to undergo mucoid degeneration it is very difficult to identify the degenerate cells with certainty when they occur separately or in small groups. But if mucicarmine, a specific stain for mucin, is used to stain the sections, the presence in tissues from which epithelium is normally absent of cells or débris stained red affords conclusive proof of cancerous invasion. In such tissues mucicarmine is a specific stain for cancer cells; not indeed, for healthy and active ones, but for those which are already dying or dead. Two years ago, from this chair, I was able to bring forward strong, if not conclusive, evidence, obtained by the mucicarmine method, that cancer of the stomach is disseminated by permeation. Some recent work which I have done on rectal cancer demonstrates the working of the same process, and affords a new and convincing illustration of the truth of the permeation theory and of my contention that cancer surgery belongs to the ablational department of lymphatic surgery.

In a recent case of rectal carcinoma in which I removed the growth by a successful combined abdominal and perineal operation I was able to demonstrate a mode of spread of the disease hitherto undetected. A longitudinal strip along the whole length of the excised bowel, measuring 10 inches, was submitted to microscopic examination by the hæmatoxylin-mucicarmine method. Conclusive evidence was obtained that the growth had spread by permeation along the mucous lymphatic plexus of the bowel at least as far as the point of section of the bowel 6 inches above the growth. How much further it had spread upwards I am, of course, unable to say. A similar spread downwards was traced as far as the region of the sphincters In the plane of tissue between the blind ends of the Lieberkühnian follicles and the underlying muscularis mucosæ, at short intervals, cancer cells, isolated or in small groups, or small masses of mucus representing degenerate cancer cells, were clearly recognisable. Some of these groups lay in spaces enclosed by visible endothelium. In a direction away from the growth, whether up or down the bowel, the groups of cancer cells in the mucous coat became gradually smaller, and the intervals between them longer. At several points near the primary growth cancer cells were detected deep to the muscularis mucosæ, penetrating from the mucous into the submucous coat. Close to the primary growth the subperitoneal lymphatic plexus showed permeation. Here, too, cancerous invasion of the muscular coat and of the meso-rectum was evident. In these situations the cancer cells had taken on the blue hæmatoxylin stain, not the red mucicarmine. That is to say, while the cancer cells in the mucous lymphatic plexus had undergone mucoid degeneration, most of the cancer cells in the muscular coat and in the meso-rectum were in a healthy state. These facts seem to indicate a difference in food-supply. The cells in the mucous plexus are bathed in a fluid which has already provided food for and received excretions from the normal epithelium lining the intestine. The cancer cells in the muscular coat and meso-rectum, on the contrary, are "fat and well-liking," because in these situations they have to face no competition with normal epithelium. Examination of this specimen showed that: 1. Permeation occurs in rectal cancer, as in other forms of carcinoma. 2. Permeation may extend very widely in the mucous plexus above and below the growth, reaching in a comparatively early stage of the disease a point at least 5 inches removed from the edge of the primary growth. The affected length of bowel appears quite healthy to ordinary naked-eye and histological examination. 3. Permeation of the mucous lymphatic plexus as a factor in dissemination is probably limited in effectiveness by the habitual early degeneration of cancer cells in this situation. 4. In the muscular and peritoneal coats cancerous invasion does not extend far from the primary growth. 5. Effective dissemination probably, as a rule, occurs through the meso-rectum or peri-rectal tissue opposite the primary growth, and this is the tissue which requires most careful removal. 6. In view of the extent of mucous permeation revealed, excision of a considerable length of the bowel above, and of the bowel down to and including the sphincters is evidently a right practice. This step has been performed frequently, but it has hitherto lacked the pathological foundation supplied by my observations. 7. The lymphatic plexus of the mucous coat of the large intestine is not situated deep to the mucous layer. It lies between the crypts of Lieberkühn and the muscularis mucosæ. In this matter the study of pathology has cleared up a doubtful point of anatomy.

These observations are sufficient to show that in cancer of the rectum, as in cancer of the breast, the problem is not the excision of an organ, but the extirpation of a diseased lymphatic area. The accurate delimitation of the probable limits of this area in each situation where cancer commonly arises within the abdomen is a problem of great practical interest.

CONCLUSION.

The record of these lectures is a mixed one of failure and success, but that is the history of most pioneer efforts. The livery of truth is usually neither black nor white, but a sober grey. Enough has been done to show the soundness of the principles employed. And, as time goes on, experience in the selection of cases will enable more certain results to be achieved, whilst operative technique will doubtless be improved. May I express the hope that the future of the operative procedures to which I have drawn your attention, and of which I have given a full description, may not be clouded by their indiscriminate application to unsuitable cases? I think too, in view of the special difficulties these operations present in the maintenance of rigid asepsis, and of the probably disastrous consequences of any failure in this respect, that they should only be carried out by surgeons in constant daily practice of the operative side of their profession.

ST. PANCRAS TUBERCULOSIS EXHIBITION.—An exhibition for the prevention of tuberculosis organised by the National Association for the Prevention of Consumption is being held in St. Pancras from April 14th to 23rd. Arrangements have been made for the use of the Maurice Hall, Working Men's College, Crowndale-road, where the exhibition will be open from 12 noon to 10 P.M. daily. Curators will be in attendance to explain the exhibits and popular lectures will be given on the cause, spread, treatment, cure, and prevention of tuberculosis each evening at 8.30 P.M., by Dr. J. E. Squire, Dr. C. Theodore Williams, Dr. T. D. Lister, Dr. Hector Mackenzie, Dr. Jane Walker, Dr. T. N. Kelynack, and others. Admission is free.

LUMBAR PUNCTURE IN MENINGITIS AND ALLIED CONDITIONS:

A CLINICAL STUDY IN CHILDREN.

BY G. STIRLING LANDON, M.D. EDIN.,

LATE HOUSE PHYSICIAN, ROYAL INFIRMARY, EDINBURGH, AND THE QUEEN'S HOSPITAL FOR CHILDREN, LONDON.

THE cases upon which this paper is founded were all seen at the Queen's Hospital for Children, London, from the end of January to the beginning of August, 1908. They comprised 4 cases of acute poliomyelitis, 4 of chronic hydrocephalus, several of so-called "meningism," and 50 of meningitis, consisting of 23 tuberculous, 10 post-basic, 7 pneumococcal, 1 each due to pneumobacillus, streptococcus, staphylococcus, and acute serous meningitis, 6 not being definitely diagnosed.

Lumbar puncture, performed in all but six of these, was followed, as a rule, by immediate examination of the fluid. The method employed was as follows. The patient lay on the side with the knees drawn up and the spine fully flexed; a line joining the summits of the iliac crests was taken as the guide to the point of entry, the space above or below—i.e., third or fourth—being used. The skin, having been previously washed, was again cleansed and dried with ether, a fine exploring needle with a stilette being inserted either in the mid-line or just to one side. If no fluid appeared twisting the needle on its axis sometimes enabled it to pierce the theca, which may be pushed before it. Anæsthetics were not generally used, but as they apparently do no harm it is kinder to employ them. In meningitis, however, immediate relief seems to follow the escape of the fluid. Suction was never employed to obtain fluid except post mortem. If blood appears the space above may be explored. Needles, centrifuge tubes, and pipettes were sterilised and cleaned with acid solution before and after use; dry sterilisation is preferable; otherwise, to prevent crystalline deposit from the boiling water entering the tubes plugs of sterilised wool were inserted. The first few drops were allowed to escape or collected separately, and the rest was collected directly into the sterile centrifuge tubes, or some was allowed to fall direct on culture media. The tubes, being covered with sterile rubber caps, were then centrifuged, one being kept lest a coagulum should form. A clear fluid was centrifuged for 5 to 15 minutes; a turbid fluid less; the supernatant fluid being decanted off and examined for albumen, &c., the deposit taken up with a capillary pipette and spread—if scanty—on one slide, more often on two; or a culture tube inoculated with it. As a rule, Jenner's or Leishman's stains were used, and where bacteria were present Gram's differential stain.

The risks of lumbar puncture in meningitis seem very slight if it be performed gradually, but in cerebral tumours it may be very real. It should be avoided where there is closure, partial or complete, of the communications at the base of the brain, between the cranial and the spinal portions of the cerebro-spinal canal, in which case lumbar puncture only drains the spinal canal and so does no good—sometimes not even diagnostically—and, in fact, does harm by allowing a distended brain to be pushed down into the foramen magnum, causing the sudden "automatic closure" described by Quincke,[1] with fatal results.

Changes in albumen content have not appeared to assist the diagnosis; if, as in urine, it were normally absent, the mere finding of it would be of value. As it is, one has to ascertain if it is increased, which is difficult unless marked, and where definitely positive other more reliable proofs have been available. Of 29 cases of meningitis it was appreciably increased in 15, varying even in the same case in different tappings. Increased albumen and increased cell content usually go hand in hand, but bear no definite ratio. There seemed to be a slight increase in 2 or 3 cases of "meningism," and in 2 out of 4 of acute poliomyelitis. The boiling test with acetic acid was employed. The reduction of Fehling's solution was seldom tried. Several observers have found it unreliable.[2]

The amount of fluid and its pressure were judged by the rate of flow from the needle. This is normally drop by drop, and is affected by the calibre of the needle, viscosity of the fluid, coughing or crying by the patient, and the patency or not of the communications at the base of the brain. "In acute diseases there may be moderate increase in pressure with severe clinical symptoms; while in chronic diseases markedly increased pressure may exist with only slight pressure symptoms, and in the latter there is frequently a gradual compensation of the brain."[1] In 32 cases of meningitis the amount of fluid was increased in 18, the pressure in 17. In two cases of acute poliomyelitis the fluid was increased—even spurting in one. The greatest increase was in acute serous meningitis. In "meningism" the amount was appreciably increased and sometimes the pressure.

The naked-eye appearance of the fluid is a very unreliable test. Turbidity may be due to leucocytosis or to blood, but either may be present and the fluid seem clear. Blood in the escaping spinal fluid may be of local origin; slight if only taken up by the needle *en route*; copious, dark, and readily coagulating if from the extra-dural venous plexus. It may be due to pre-existing subarachnoid hæmorrhage—meningeal, ventricular, or spinal. If the hæmorrhage be more than two days old the red cells will be laked, and the deposit after centrifuging consist of red cells and their débris, with supernatant fluid tinged by the pigment.[3] Even a subdural hæmorrhage may give a tinged fluid owing to diffusion of pigment, but there will be no red cells in the spinal fluid.[3] With a hæmorrhage complicating meningitis the fluid is said to be uniformly tinged with blood and tends to coagulate, the clot containing blood cells and leucocytes derived from the meningeal effusion; the supernatant fluid being also tinged yellow.[4] In hæmorrhage associated with cerebral injury, or in cerebral hæmorrhage, the pinkish fluid does not usually tend to coagulate; if recent, red cells are present, which on centrifuging fall to the bottom, leaving a clear fluid; if older, the supernatant fluid will be tinged yellow and the red cells laked. The determination of the source is often very difficult; and I have often found it almost impossible to say whether a slight contamination was merely local or due to a pre-existing hæmorrhage.

By far the most important characters of the spinal fluid, clinically, are its cytology and its bacteriology. These should be investigated as soon as possible, as changes rapidly take place in the cells, rendering them difficult to identify, and organisms may die out or become incapable of cultivation, or contaminations occur. Normally lymphocytes are difficult to find: some say there should not be any. Any polymorphs are pathological, though some may be due to an accidental blood contamination. In this series cell counts were made from smears from the centrifuged deposit. Stewart[5] found the more accurate counts, with special counting cells, merely corroborated the rougher method; which has the advantage of supplying permanent results, combined with a bacteriological record. The cytology embraces cell-content and cell-type, the latter being the more important. Just as meningitis has been classed as vertical or basal according to the aspect of the brain involved, so special types of leucocytosis have been allocated to particular diseases. While these distinctions may hold true for the majority of cases, they are unreliable in the diagnosis of individual cases. The point of importance, as a rule, is whether it is a mononuclear or a polymorph leucocytosis. Roughly speaking, a polymorph effusion suggests a microbic infection other than tubercle, though this series includes 7 cases of tuberculous meningitis with polymorphs from 40 to 85 per cent. French[6] observers have also described an aseptic polymorph effusion with "intact" cells, which they ascribe to toxins acting at a distance from a localised focus and having a favourable prognosis. Mononuclears occur in tubercle, syphilis of the central nervous system, the parasyphilitic affections, herpes zoster, acute poliomyelitis, mumps,[7 8 5a] lymphatic leukæmia, chloroma,[9] trypanosomiasis,[10] some cerebral tumours,[5] &c. They may also replace the polymorphs in the later stages of microbial infection, and are then considered of good prognosis. I have found a slight increase of lymphocytes in "meningism."

Somewhat different views obtain as to the exact significance of the polymorph in the spinal fluid. Buzzard[7] regards it as the expression of a phagocytosis in response to a microbial invasion; the mononuclear perhaps preceding it, due to irritation of the meninges, as seen in herpes zoster and acute poliomyelitis. To others it expresses the acuteness or intensity of a process, whether mechanical or microbial, the mononuclear speaking for a subacute or chronic condition. In support of this latter view Purves Stewart[5]

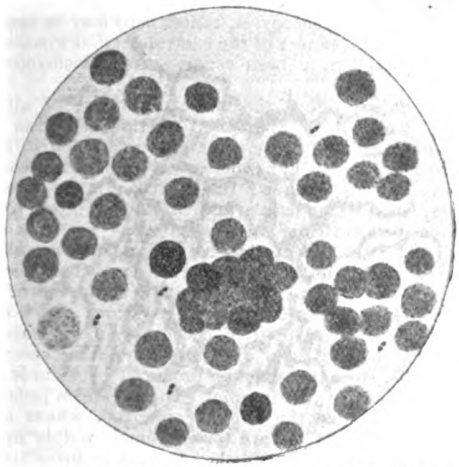


FIG. 1.—Pneumococcal meningitis. Secondary. (Jenner's stain.)—A. H. Second tapping. Atypical mononuclear effusion three days before death. Two or three diplococci in this field. Clinical symptoms latent. Otorrhœa and pneumonia present.

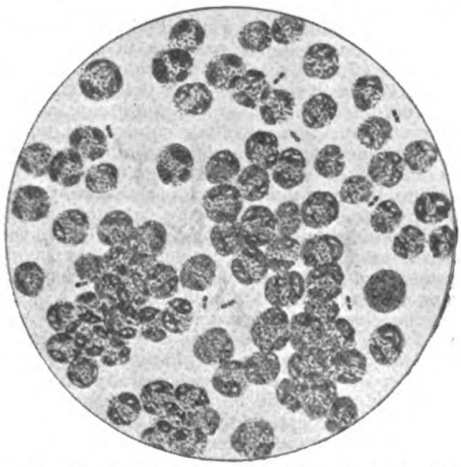

FIG. 2.—Pneumococcal meningitis. Primary. (Jenner's stain.)—E. F. Typical polymorph effusion (over 90 per cent.). Comparatively few diplococci; few hours before death. Clinically, marked meningitic symptoms.

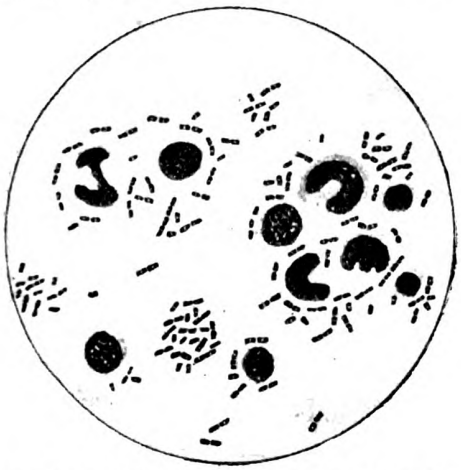

FIG. 3.—Pneumobacillus meningitis. (Leishman's stain.)—H. P. Second tapping; immediately after death. Moderate leucocytosis. Mononuclears slightly predominate. Large numbers diplobacillus. Clinically, bronchitis, diarrhœa, hydrocephaloid condition.

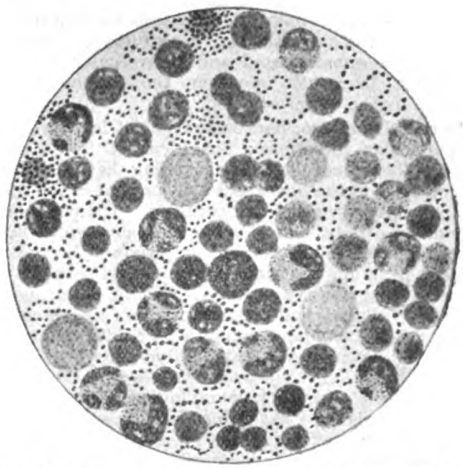

FIG. 4.—Streptococcal meningitis. (Jenner's stain.)—A. W. Large leucocytosis; mononuclears 80 per cent. Copious streptococci in chains, &c. Few hours before death. (More polymorphs in this "field" than elsewhere.) Clinically, periostitis tibiæ; latent symptoms.

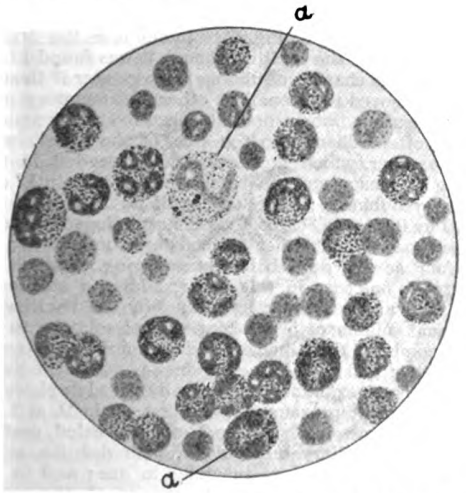

FIG. 5.—Tuberculous meningitis. (Jenner's stain.)—J. G. First tapping; mixed infection. Diplococci in two cells (*a*). Polymorphs, 45 per cent.; in third tapping reduced to 25 per cent. Gram-negative diplococci in culture from this fluid; also in smears post mortem. Copious tubercle bacilli in coagulum. (See Fig. 6.)

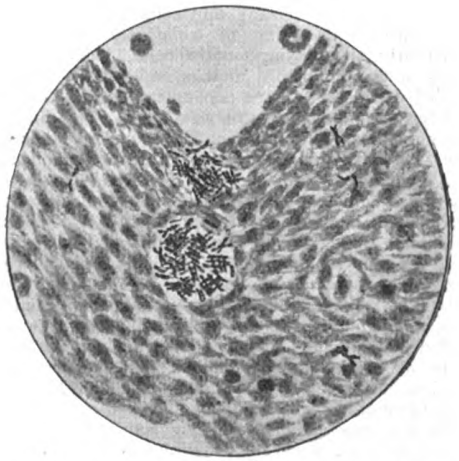

FIG. 6.—Tuberculous meningitis. (Carbol-fuchsin and methylene blue).—J. G. Coagulum teased and stained Ziehl-Neelsen method. Shows two clumps of tubercle bacilli and some scattered.

N.B.—These figures are reproduced from colour drawings of actual "fields" drawn with 1-12th oil immersion lens by the author.

instances the production of a spinal polynucleosis after intraspinal injection of sterile particles in monkeys, also the polynuclear effusion seen in the acute pyrexial attacks in paresis. Peyton Rous [8] also avers that the irritation caused by the needle in a lumbar puncture may induce a polynuclear effusion, thus affecting subsequent tappings; no definite instance of this has occurred in this series even in fluids removed on successive days. The study of inflammation seems to show that, in acute conditions, the polymorph usually appears early, whether the irritant be mechanical or microbial, being replaced by the mononuclear in the chronic or convalescent stage, though some irritants may determine the presence of a particular cell. In chronic conditions, however, or "where toxins have been acting over a long period," the mononuclear predominates.[10]

In addition to the blood leucocytes, local tissue cells or endothelial cells may act as phagocytes,[11 34] proliferating for the purpose, and may cope successfully with an infection, especially if the onset be gradual; otherwise they are reinforced by leucocytes from the blood. Should the infection be too virulent, or the resistance delayed or exhausted, there may be no leucocytic reaction, as in fulminant meningitis. Maiella [12] found that in dogs little or no spinal leucocytosis occurred if the meningitis proved fatal within two or three days. Marinesco,[13] also in animals, found that inoculation of the subarachnoid space with various bacteria gave results varying from no leucocytic reaction at all to a meningo-myelitis and a leucocytosis varying in nature and extent with the organism and its virulence. Bacteria even invaded the subarachnoid and perivascular spaces without causing a leucocytic reaction, though the tissues were affected by the toxins secreted.

In the blood, also, particular types of leucocytosis respond to particular infections; but I cannot find mention of a relation being considered as existing between the type of leucocytosis in the blood and that present in the spinal fluid. There are, however, several parallels. The polymorph is the prominent cell in blood and spinal leucocytosis in epidemic and sporadic cerebro-spinal meningitis, and La Fètra [14] found that when serum treatment was beneficial both the blood and spinal leucocytosis were reduced, both rising again in the relapses. Polymorph leucocytosis of the blood is often present in tubercular meningitis,[15 25] and may occur in the spinal fluid, the typical spinal lymphocytosis being comparable with the relative increase of the lymphocytes in the blood seen in favourable cases of tuberculosis.[10 16] Lymphocytosis of both blood and spinal fluid occurs in lymphatic leukæmia and in trypanosomiasis, in which diseases the lymphatic tissues appear to bear the brunt of the infection. It would seem that in acute toxic and infective conditions of the nervous system an early round-celled infiltration, perivascular and meningeal, is the prominent characteristic [17 18 19]—e.g., acute poliomyelitis, these lymphocyte-like cells being derived mainly "by proliferation of cells present in the perivascular sheath and walls of the vessels," any appreciable influx of polymorphs from the blood being of relatively late occurrence.[17] Apparently these lymphocytic cells, local in origin and found in the arachnoid meshes and fluid, provide the first line of defence, perhaps accounting for the comparatively long list of conditions, mostly subacute or chronic, in which a mononuclear effusion is found. Even a pyogenic meningitis may, if slowly progressing, exhibit a mononuclear effusion, as in a case, described later (see Fig. 1), where three tappings gave a mononuclear spinal effusion, polymorphs appearing 24 hours before death, as if, after an unsuccessful defence by the local cells, a general reaction had followed. In another case with latent symptoms the spinal fluid at death contained copious streptococci and yet over 80 per cent. mononuclear cells (see Fig. 4). So a mononuclear type early in the case, far from being of good prognosis, may mean an inefficient support to the first line of defence. The mode of invasion might probably influence the type of effusion, an intense or sudden invasion (? hæmatogenous) probably causing a general reaction and polymorph effusion; while a mononuclear type may be due to a particular infection (e.g., tubercle or syphilis) or may represent a "local" response to a subacute or more gradual invasion (? lymphogenous), the appearance later of polymorphs suggesting failure of the first line of defence and a consequent general reaction, due either to the spread of the original infection or to the arrival of a fresh enemy in the shape of a mixed infection.

In addition to leucocytes, cancer cells may be found in the spinal fluid in cancer of the central nervous system,[20 55] and "yeast cells" have been reported in blastomycosis of the brain.[21]

Bacteriology offers the most conclusive of all positive results obtainable by the spinal fluid. Sometimes using the fluid itself as a culture medium, by incubating it, may yield organisms which would otherwise have been missed. I have by this means obtained tubercle bacilli in smears after several days' incubation and a coccus after 24 hours, neither being visible in the previous smears, and both confirmed later. Bacteria may be present without a leucocytosis, while, failing other evidence, the opsonic and agglutinative reactions of the fluid may be of positive value. Many bacteria, including various types of Gram-negative and Gram-positive cocci, have been isolated from the spinal fluid in cases clinically simulating cerebro-spinal meningitis, since the infection produced by them is generally cerebro-spinal in distribution. The organism isolated, however, may not be the original organism, which may have died out or resist culture (even though visible in smears), either due to faulty methods or delay in investigating, the organism found being only a secondary or terminal infection.[22] Bacteria responsible for spinal disease are especially prone to die out early. In some mixed infections the organisms seem to reinforce one another, as in the case of the diplococcus crassus and meningococcus,[23 56] which may also be true of the leptothrix organism and the meningococcus.[24]

Tuberculous Meningitis.

In tuberculous meningitis the spinal fluid may appear normal or increased in pressure and amount—one form of "acute hydrophalus"—and be clear or turbid with or without appreciably increased albumen. The more acute the case the more turbid and albuminous the fluid. In 16 cases the fluid was increased in amount in 7; and in pressure in 5; clear in 2; opalescent or turbid in 14. The association of a clear, or nearly clear, fluid with many polymorphs proves generally, I think, to be tuberculous. Albumin was appreciably increased in 7 out of 13 cases in which it was noted. Robinson [25] found slight opalescence in 12 and turbidity in 4 in a series of 19 cases.

Of these 23 cases, the bacillus was not looked for in 9. It was found in the 14 cases examined for it; in all of 10 in which the coagulum was examined—as a rule quite readily; and in smears from the centrifuged deposit in 4—after repeated and protracted search; in one, only after incubating the fluid for several days before centrifuging. The typical veil-like clot, suspended like a fine cobweb from the surface of the fluid, is itself strongly suggestive. It was present in the 10 cases examined for it; Robinson obtained it in 18 out of 19 cases. Removed with a pipette, teased out on a slide and stained by the Ziehl-Neelson method, it provides a most reliable and expeditious method of finding the bacillus, which may be present in it in twos or threes, or in large numbers (see Fig. 6). In one case the first tapping failed to reveal the bacillus, though it was found in the next. Probably the chances of finding it are greater if the coagulum be not removed too soon. In other inflammatory conditions the coagulum, when present, occurred in opaque, friable flakes, often adhering to the sides of the vessel, in contrast to the other, which is elastic and suspended in the fluid. Using this coagulum, the bacillus was found in 17 out of 19 cases by Robinson; in 25 out of 31 by Forbes [26]; in 38 out of 40 by Bernstein,[27] who adds the centrifuged deposit to the teased coagulum. Other methods are: incubating the fluid for four or five days before centrifuging it, which was successful in one case in this series; adding a sterile fleece to the fluid and searching its meshes for the bacillus; adding an equal volume of 5 per cent. phenol solution to the fluid to precipitate the albumen and examining the centrifuged deposit [28]; and inoculating a guinea-pig with the fluid.

In 19 cases examined a practically pure lymphocytosis was obtained in 7, polymorphs were present in 9, and no cytological evidence in 3. These 3 cases revealed, post mortem, widespread miliary tuberculosis, with definite tuberculous meningitis with copious tubercles in one; and in the other two an early meningitis with opacity of the membranes, and turbid effusion at the bases, spreading into the Sylvian fissures, but without macroscopic meningeal tubercles, definite optic neuritis being present in one of them. At least three cases of tuberculous meningitis without tubercles have been reported [29 57]; in all there was an absence

of tubercle formation throughout, the condition being recognised by microscopical examination, and in one case[30] by recovery of the bacillus from the spinal fluid. Since in my cases microscopical investigation of the tissues was not employed, nor the spinal fluid bacteriologically examined, the condition may possibly have been a serous meningitis, caused by toxins rather than by an actual invasion by the bacillus. Absence of leucocytes is reported by Forbes (2 cases) and by Rénon and Tixier,[31] who in one case obtained no cytological evidence in seven tappings during the last 25 days of the disease. In 16 cases lumbar puncture was performed 33 times, varying from one to four times per case, depending on the clinical symptoms, which the operation temporarily relieved. Polymorphs were found in 9 cases, varying from 4 per cent. to 85 per cent., being the predominant cell in 4 cases, and reaching over 40 per cent. in 2 others, a pure lymphocytosis prevailing in the remaining 7 cases.

What do these polymorphs denote? They may be present at the outset and persist, or may only appear late. They can hardly represent a change from a local to a general reaction, the meningitis usually being only a part of a general tuberculosis; and against their representing acuteness is the fact that some cases show a pure lymphocytosis which from clinical and pathological evidence are equally acute or severe infections. In one such case of 16 days' duration, clinically very acute, with copious bacilli in the spinal fluid and much lymph post mortem only lymphocytes were present in three tappings and less than 10 per cent. polymorphs in the fourth. In another, clinically a mild case with indefinite symptoms till within three days of death, polymorphs in three tappings ranged from 50 per cent. to over 75 per cent., a large cavity at the base of one lung being found at the necropsy. If the rapidity of the course is any criterion of its acuteness, some of the cases with lymphocytes were as acute as those with polymorphs; and this is confirmed by the clinical features. Thus the average duration in 4 cases with pure lymphocytosis was 14 days, the 2 tested proving sterile in culture. In 3 others the duration averaged over 3 weeks. Of 8 cases with polymorph leucocytosis, in 4 with the duration ranging from 5 to 14 days, polymorphs predominated in only 1; while they predominated in 3 out of 4 others, whose duration ranged from 3 to 6 weeks. Of these 8 cases, in 5 a mixed infection was suggested by obtaining a culture in these, 2 others proving sterile, organisms being seen also in smears in 4 and confirmed by culture in 3.

The organisms found in smears were in two cases Gram-positive cocci somewhat resembling the pneumococcus; the cultures were taken after the fluid had been standing and were contaminated. In another a faintly staining bacillus, in some places apparently branching, no culture being taken in this case. The other organism seen in smears was an intracellular coccus seen only in the first tapping (see Fig. 5), being at first regarded as a post-basic case, giving a feeble growth originally on nasgar, but more vigorous in subculture; growing also on Drigalski medium as a Gram-negative bean-shaped diplococcus. It was found also extracellular in smears from the ventricular fluid post mortem. Double otorrhœa was present and copious tubercle bacilli (see Fig. 6) in the spinal fluid. The last, not seen in smears, was obtained in culture on nasgar as a feeble growth, being more vigorous in subculture, growing also on Drigalski medium as a Gram-negative bean-shaped diplococcus, appearing in pairs and tetrads. In these last two the primary growth consisted of one or two discrete whitish circular colonies with smooth outline, but developing more yellow pigment than did the cultures in post-basic cases.

So the presence of polymorphs in tuberculous meningitis may, in at least some cases, be accounted for by a mixed infection of the meninges (or of the patient) as found by others, Ross [32] and Bernard [33] finding a change of type from mononuclear to polymorph coincident with infection by pyogenic organisms. The infection may be from the ear, or a periostitis,[4] or a cavity in the lung,[34] since "the majority of cases of pulmonary tuberculosis are combined infections,"[35] this being the explanation given for a case of streptococcal meningitis complicating phthisis, no other source of infection being discoverable,[36] and may also account for the mixed infection in my case in which a large vomica existed in one lung.

A polymorph leucocytosis at the outset, especially if large, may be due to a hæmatogenous or sudden infection, as when large numbers of bacilli enter the blood-stream from rupture of a caseous gland into a vein, for polymorphs appear to exert no power over the tubercle bacillus, unless, perhaps, when in the blood.[34] A lymphogenous or more gradual infection is probably more often the case. Maiella[12] found experimentally that a cortical encephalitis gave rise to a polymorph effusion, and that a cerebral abscess without cortical encephalitis was unaccompanied by a spinal leucocytosis. Tuberculous meningitis is really a meningo-encephalitis, the encephalitis varying in degree and extent. That the presence of polymorphs may bear some relation to the amount of encephalitis was suggested by a case of six weeks' duration, in which necropsy revealed extreme softening, more marked on one side, and extensive meningitis with copious tubercles; clinically, head retraction and convulsive movements were marked, the spinal fluid turbid, with a large pure lymphocytosis in the two first tappings and 50 per cent. and 60 per cent. polymorphs in the two last, being sterile in culture and with large numbers of tubercle bacilli in each tapping.

While the cytology of tuberculous meningitis is not pathognomonic, the association of the typical coagulum with a lymphocytosis is very suggestive, the discovery of the bacillus being conclusive, and by searching the coagulum definite proof should be available in most cases.

In the 23 cases the average age was 2½ years; 7 being under 1 year and the youngest 3½ months. The duration, so far as ascertainable, was from 5 days to 6 weeks. The most rapid case (aged 2 years) was well on Saturday, being a little drowsy in the evening; facial paralysis developed next day, for which she was admitted; she was then slightly tremulous on sitting up, with a rather vacant, drowsy look and slight squint. Lumbar puncture gave a scanty clear fluid with 45 per cent. polymorphs, no cocci, and albumen slightly increased. Only 1 or 2 tubercle bacilli were found in a smear. She was removed home on the Monday morning and died on Wednesday with symptoms of meningitis. Two cases dated from a definite cerebral injury received when in apparently perfect health, and ran an acute course of 13 and 14 days, necropsy revealing marked vertical as well as basal meningitis; the cerebral condition being much in advance of the changes elsewhere, one showing a small calcareous focus in one lung, the other a caseous mediastinal gland. Tubercle of the choroid was present in 2 cases, without changes in the disc, in one a large pigmented obsolescent tubercle being accompanied by several recent "satellites." Optic neuritis was present in 6, one being of the "choked disc" variety. Squint was noted at some period of the illness in 17, and facial paralysis in 3, being persistent in 1. A modified hemiplegia was present in 3 cases, lasting from a few hours to 2 or 3 days. Hemiplegia and facial paralysis seem to be generally of early onset and short duration; 1 case was brought to hospital for the facial palsy, another for the hemiplegia; while a case which on admission closely resembled this—with paresis of the left arm and leg, cervical rigidity, and a small spinal lymphocytosis—proved to be acute poliomyelitis. Robinson [25] found a partial or complete hemiplegia in 5 cases, and a cataleptic condition in 1; this was also noticed once in this series. Physical signs may be very latent even with definite pulmonary involvement; of 2 cases of meningitis with signs of consolidation, 1 having a spinal lymphocytosis was pneumococcal meningitis; the other, admitted as marasmus (aged 9 months), had no spinal leucocytosis at all, necropsy revealing a typical tuberculous meningitis. Another case, admitted as whooping-cough and bronchopneumonia with intense cyanosis, had double optic neuritis, blood-stained spinal fluid without appreciable leucocytosis, and at the necropsy obvious meningitis without meningeal tubercles, but with widespread tubercles elsewhere.

Lumbar puncture often gave marked, though temporary, relief, especially where much movement was present, but it never restored consciousness.

With regard to prognosis, hope is usually regarded as being proportional to the chances of a mistaken diagnosis, the meningitis being only one, often a late, manifestation of a general tuberculosis. That it may, however, be the chief, or perhaps the only, lesion was suggested by two cases where the necropsy showed advanced meningeal changes with very slight evidence elsewhere. Tooth [37] has recorded a case of 33 days' duration with only meningeal tubercle at the necropsy, and normal temperature throughout. Such subacute cases resemble tuberculous peritonitis, which also may occur alone or as part of a general infection, and in which, especially the form with fluid, good results have followed laparotomy. Stiles [38] had two recoveries after trephining and allowing escape of fluid in which the tubercle bacillus was found. A case (M. M.) described later was possibly of this nature. Martin [2] has collected a number of cases of tuberculous meningitis with remissions and death from relapses after intervals of from four months to two years, diagnosis depending on inoculation of guinea-pigs with the spinal fluid, isolation of the bacillus in one case, and discovery of the old meningitis at the necropsy; also several instances of recovery verified by isolating the bacillus from the spinal fluid. Some of these may have been localised tuberculous meningo-encephalitis, described by Oppenheim [39] as circumscribed, favouring the convexity and often simulating cerebral tumour, which he had verified years after on necropsy, and in which operation with ablation had resulted in recovery in some cases, and in an extension of the process in others; while some may have been a serous meningitis due to toxins, an "acute tuberculous fever"—Osler [35] stating that "in

the fluid obtained by lumbar puncture the tubercle bacillus may be abundant, even when there is no active meningitis."

M. M., aged 9 years, with a tuberculous family history, "always delicate," had severe headache for nearly 3 weeks, and vomiting, ataxia, and drowsiness for several days before admission, when cerebral vomiting, lateral nystagmus, unilateral weakness of facial muscles and foul double otorrhœa were present, with a high spinal lymphocytosis. Unconsciousness, incontinence, and choked disc developed and meningitic cry; then a marked, but temporary, improvement for 2 days, followed by relapse to the former condition, with increased papillitis. Radical mastoid operation was then performed on one side, but no pus was found; the membranes appeared to be healthy but slightly bulging, and on incision a large amount of clear fluid escaped. From this time improvement began and persisted. The spinal fluid, examined 3 times before operation, showed a high pure lymphocytosis, no organism being seen; again, 2 weeks and 4 weeks after the operation, it was the same with still a large excess of fluid. Two smears from the last tapping, however, showed a few more polymorphs and several large organisms, apparently a coarse coccus or short thick bucillus. These, if not contaminations (and the fluid was examined immediately after removal) support Weichselbaum's statement that bacteria may be present in the spinal fluid without necessarily causing meningitis, for they gave rise to no symptoms, the child then being up and awaiting discharge. Cultures were not taken, nor was a coagulum looked for, it being prior to my adoption of that method, but in a smear from the fourth tapping what were believed to be 2 or 3 tubercle bacilli were seen. There were no pulmonary signs, no choroidal tubercles, the papillitis being in no wise diminished two weeks after the operation. The temperature never exceeded 99° F., and this with the severe symptoms and spinal lymphocytosis seems to negative an otitic meningitis. She left hospital 3 months after admission apparently quite well, her mother writing 14 months later that there is still double otorrhœa, that she is very delicate mentally and physically, and only just returning to school. One sister has since been under treatment for surgical tuberculosis.

This case in several particulars resembled a case of tuberculous meningitis, which for a time simulated cerebral tumour, with choked disc, nystagmus, facial palsy, and high lymphocytosis.

E. S., aged 10 years, probably a case of tuberculous meningitis with remission, was admitted in November with severe cerebral symptoms—vomiting, hemiplegia following a convulsion, head reaction, constipation, and marked double optic neuritis. Improvement ensued, the neuritis being followed by atrophy. The spinal fluid was not examined till 24 or 48 hours after removal, no leucocytosis or organism being found. When I first saw her in January she was regarded as a case of cerebellar tumour, and was tremulous, emotional, quite blind, at times very drowsy, and with cerebellar ataxy; there was also an old aortic bruit. The temperature never exceeded 99° F. No pulmonary signs were present. In March she developed a swinging pyrexia rising to 104°, with a relatively slow pulse. The Widal test was doubtfully positive in the third week of the pyrexia and negative 8 days later. There were some typhoid-like spots on the abdomen, which was rather full. Marked drowsiness was the only cerebral symptom and a modified Cheyne-Stokes type of respiration for a few days before death, which occurred in the fourth week of the pyrexia, 5 months after admission.

Necropsy revealed no tumour, but a collection of yellow lymph at the base and lower ends of the Sylvian fissures and a few whitish hard spots on the membrane; otherwise no tubercles. The pituitary body was hard and nodular and in section apparently caseous. The spleen was not enlarged. In the lower ileum and cæcum were several small ulcers. There was no macroscopic evidence of tubercle in the thorax or abdomen. The tubercle bacillus was not looked for, so this case has not been included in this series; but it would seem to be a case of tuberculous meningitis which had quieted down, with death from the intestinal condition, perhaps aided by old cardiac disease.

In tuberculous meningitis the Widal reaction may be positive, as found by Robinson[25] in 3 out of 8 cases, being positive twice in one case closely resembling typhoid; a blotchy rash also occurs which may be mistaken for typhoid spots.

The treatment in reported cases of recovery has varied from mercurial inunction and tuberculin injection to leeching and repeated lumbar puncture or trephining. Just as venesection is more effective, when indicated, than the slower method of leeching, so trephining may well be more effective than lumbar puncture, as seen in cases of cerebral tumour. Whitla[40] suggests the anæsthetic may be responsible for some of the benefit following laparotomy in tuberculous peritonitis; if so, why not in meningitis? Darling[41] and Da Costa[41] have both shown that a general anæsthetic is followed by an appreciable blood leucocytosis. Modern methods seem to negative the absolutely hopeless prognosis, and also encourage the hope that early trephining with drainage might save at least some lives which at present are merely allowed to drift. Judging from the reported cases, the subsequent mental condition is apparently good in those that recover, a further justification for interference.

Post-basic Meningitis.

In the 10 cases of post-basic meningitis the fluid was turbid in 8 and clear in 2, in large excess in 7, with raised pressure in 5. Hydrocephalus was present in all; in 2 only scanty fluid was obtained at first and "dry taps" after, apparently due to a collection of thick gelatinous lymph in the fourth ventricle, one of these being relieved by tapping the lateral ventricle. In 1 only a few drops of blood-stained fluid were obtained on two occasions, apparently due to "automatic closure" of the foramen magnum by the distended and softened brain being pushed down into it, the "tonsils" being elongated and moulded so as to fill the foramen "like a plug."[1] A polymorph leucocytosis was present in 8, polymorphs being in large excess with many intracellular cocci in 5.

In A.G. the first two tappings gave 60 per cent. and 75 per cent lymphocytes, with a very few intracellular cocci, visible only in the first tapping, but typical cultures obtained from both. The last tapping showed 90 per cent. polymorphs but no visible cocci, and preceded by some 48 hours a marked change for the worse in the symptoms, the post-mortem findings being typical. The clear fluid in one case was not examined for about 24 hours; the scanty cells then found were practically indistinguishable.

In J. D. the first tapping gave scanty fluid with 55–60 per cent. lymphocytes and no cocci visible in smears, but after about 24 hours' incubation Gram-positive cocci in pairs and chains were found. The second tapping gave only a few drops in which lymphocytes amounted to about 80 per cent., two subsequent attempts being "dry taps." Post mortem intra- and extra-cellular cocci were obtained in smears and culture from the lymph and ventricular fluid and were persistently Gram-positive.

Another case, resembling this in the latent character of the symptoms, gave in the first and second tappings scanty yellowish fluid in which lymphocytes predominated; no cocci were visible in smears, but a Gram-negative coccus, growing in pairs and tetrads, was obtained in culture Owing to the failure to relieve the hydrocephalus by lumbar puncture the lateral ventricle was tapped through the anterior fontanelle under an anæsthetic, a large amount of fluid escaping containing over 50 per cent. polymorphs, in some of which numerous diplococci were found, apparently Gram-negative, culture giving a Gram-negative diplococcus and staphylococcus, smears from the ventricular lymph post mortem showing a few intracellular cocci, apparently Gram-negative. This organism appeared to differ from the diplococcus of Still.

So in one case symptoms suggesting post-basic meningitis were due to a coccus Gram-positive and intracellular, and in another to an atypical Gram-negative diplococcus. In two cases cocci apparently absent from the smears from the freshly centrifuged fluid were obtained after incubation. In several cases smears from cases of tuberculous and post-basic meningitis have been very similar. Two fluids from the latter disease were examined for tubercle bacillus, and two cases of the former disease with marked retraction were at first suspected of being post-basic. The findings by lumbar puncture depend largely on the patency of the communication at the base of the brain, which may be interrupted by adhesions; or a thick gelatinous lymph which in two cases appeared to fill the fourth ventricle and block the escape of fluid; or by actual occlusion of the foramen magnum by the softened distended brain being pushed down into it and which lumbar puncture only tends to aggravate. All my cases died and in none did a preponderance of mononuclears justify a hopeful prognosis. Goggia is reported[2] as finding a mononuclear type of fluid throughout a fatal case of meningococcal meningitis. In one case there seemed very little amiss save slight cervical rigidity, a full fontanelle, and an objection to being handled; it actually put on weight. In the fifth week marked head-retraction and vomiting set in abruptly with symptoms of collapse and death four days later. The first two tappings showed a preponderance of lymphocytes, the last a change to 90 per cent. of polymorphs. A few cocci were seen only in the first tapping and a typical culture obtained, the post-mortem findings being typical.

The average age was 9 months, 2 cases being over one year (13 months and 2 years). The eldest, aged 2 years, was clinically the most acute, with high temperature, herpes and a purpuric eruption, and copious typical intracellular diplococci. As a rule the temperature remained low. Vomiting was generally marked and persistent, yet many seemed to take the bottle well, 2 cases actually putting on weight for a time. Optic neuritis was not noted, but marked pallor of the disc and apparent blindness were noted in 3. Necropsy in 8 showed marked ventricular distension, with absence of obvious meningitis on the vertex. In fact, the pale vertex appeared to suggest an anæmia, and in several cases the terminal stages closely resembled that seen in cases dying with diarrhœa (hydrocephaloid), in which "arterial anæmia of the brain" is said to be present,[42] as in the case with abrupt alteration in symptoms mentioned above. The result of puncturing the ventricle direct, though it probably prolonged life slightly, was not encouraging.

Hydrocephalus.

Four cases of chronic hydrocephalus, apparently following post-basic meningitis, were admitted. In one, a feeble-minded girl of 8 years, concealed hydrocephalus apparently existed, the result of simple meningitis in infancy. The spinal fluid was in appreciable excess, clear, devoid of cells and of albumen. It was suggested she was less fidgety after its removal. Two others were seen 4 and 12 months after

meningitis, the cranium in the former being very large, with patent sutures, the removal of large amounts (from 3 to 5 ounces) of fluid at intervals producing at first apparently a slight improvement. Once the fluid showed a glistening turbidity, apparently due to a degenerated cellular débris. The last case, seen three months after meningitis, was tapped five times without any ultimate improvement. In the first tapping were a few mononuclears; the second next day showed a high polymorph leucocytosis; no organisms were seen and it was sterile in culture. These polymorphs may have resulted from irritation due to the previous day's tapping, as described by P. Rous [8]; if so, it was the only instance in this series. The subsequent tappings contained mononuclears like the first. All the cases left hospital *in statu quo*.

In acute hydrocephalus, puncture should be performed early and repeated to prevent over-distension, which when once formed tends to persist, on account of the inelastic nature of the cerebral substance. But in long-standing hydrocephalus, when parts of the brain have undergone atrophy from prolonged pressure, and when secretion continues from over-dilated cavities, lumbar puncture is generally only of transient benefit. In young children, however, it may, by relieving over-distension, allow of more development of the brain substance than would take place if the pressure remained constant.[1] Or perhaps, by removing large amounts of fluid, a condition of cerebral hyperæmia may be induced with consequent improved nutrition of the cerebral tissues.[43] Concealed hydrocephalus may be similarly benefited. To obtain any lasting benefit it would probably be necessary to repeat the process, at intervals, over a long period.

Pyogenic Meningitis.

Under the head of pyogenic meningitis are grouped the infections due to the pyogenic organisms, of which *pneumococcal meningitis* is the commonest form, being third in order of frequency of all forms of meningitis. This series included 7 attributed to the pneumococcus, as judged by the findings in smears and culture. Two were primary, no other focus being discoverable, and directly followed definite cerebral injury received while in perfect health. The other 5 were secondary—2 to localised empyema; 3 to purulent otitis, in 2 with long-standing otorrhœa, in the other, only discovered unexpectedly at necropsy. These primary and secondary cases differed both clinically and in the results of lumbar puncture. In the primary cases symptoms appeared abruptly, about 24 hours after the injury, were marked, fits being prominent, and ran a rapid course, being fatal on the third and fourth day. The spinal fluid showed typical changes, being turbid, increased in amount, in pressure, and in albumen, and with a high polymorph leucocytosis (over 90 per cent.), one with copious organisms, the other with comparatively few. (See Fig. 2.) Both had a thick layer of pus covering the vertex and infiltrating the membranes throughout. In one there was a large polymorph leucocytosis of the blood, and apparently some intracellular organisms visible in smears. The secondary cases generally ran a longer course, with symptoms latent or absent till near the end, the evidence of lumbar puncture being often unreliable till near the close. The above apparently holds true for all forms of pyogenic meningitis, which, as a rule, is a secondary or terminal infection, though marked variations occur according to the virulence of the infection. The average duration in the secondary cases was about 9 days, the onset being difficult to determine.

A. G. (1), aged 1½ years, admitted with suspicious history, during 8 days in hospital showed no signs of meningitis except marked irritability, sat up in bed to within 36 hours of death, ran a low temperature, and 4 days before death yielded a spinal fluid increased in amount and pressure, but otherwise normal. One did not feel justified in repeating the lumbar puncture. Necropsy revealed purulent vertical meningitis and turbid spinal fluid teeming with organisms, pyopericardium, and a localised inspissated empyema of about the size of a crown piece, which had apparently been twice punctured by the exploring needle without result. The lungs were crepitant throughout.

A similar case, A. B., aged 4 months, with broncho-pneumonia, after 2 or 3 weeks' illness, developed head retraction; tubercle was suspected, but necropsy disclosed a small inspissated empyema of about the size of a penny, and purulent basal meningitis. Lumbar puncture twice performed gave only a few drops of blood-stained fluid, which was not examined.

Of the 3 cases associated with purulent otitis, in H.D., aged 2 years, the otitis was unsuspected during life. Operated on 12 months previously for empyema, he had been under treatment for persistent pulmonary symptoms suggesting fibroid lung, and when apparently convalescent developed symptoms which suggested tuberculous meningitis: next day lumbar puncture gave turbid increased albuminous fluid with a high polymorph leucocytosis and swarming with diplococci, death following 3 days later. Necropsy that day discovered an intense purulent meningitis, pus in one ear, and marked pulmonary fibrosis. Here meningeal symptoms definitely appeared only 4 days before death.

A. G. (2), aged 6 years, with long-standing otorrhœa, developed meningitic symptoms 3 weeks after the third operation for it, lumbar puncture 2 days later giving a turbid fluid with large polymorph leucocytosis—the cells being unusually well preserved—and with only a few pneumococci. Trephining showed apparently healthy membranes and exploration for abscess was negative, the condition being unrelieved. Death occurred 4 days later, necropsy disclosing a basal purulent meningitis, pneumococci being isolated from the pus as from the spinal fluid.

A. H., aged 7 months, was admitted with a history of vomiting, retraction, and double otorrhœa, which had stopped on one side 2 days previously. Septic meningitis was suspected, but a spinal lymphocytosis and the development of signs of pulmonary consolidation suggested tuberculous meningitis. No tubercle bacilli were found, but in a corner of a smear from the second tapping 2 or 3 diplococci were seen among the lymphocytes. (See Fig. 1.) The third tapping gave only a few drops still mononuclear in type. On the seventh day of admission, and 24 hours before death, the symptoms, hitherto most indefinite, became marked, with fits, squinting, &c., the spinal fluid then showing a high polymorph leucocytosis with copious diplococci.

Necropsy revealed marked purulent vertical meningitis, and no evidence of a ruptured abscess or of pus in the ear. This case has been previously referred to as showing a lymphocytosis even in the presence of pyogenic bacteria. It also is an instance of the association of pneumonia and meningitis.

The temperature in the two primary cases varied from 103° to 105° F. in one, and from 104° to 107° in the other. In the secondary cases the pyrexia appeared to be influenced less by the meningeal infection than by concomitant conditions (e.g., pulmonary) elsewhere. In the two cases associated with empyema, pyrexia was marked in the one with broncho-pneumonia and very slight in the other, in which the lung was not affected. In the case with pneumonia and otorrhœa the temperature was high and the symptoms very indefinite. Lumbar puncture usually brought temporary relief and a fall of temperature; it gave no clue to the condition in 2 cases 4 days before death, and in another gave only a mononuclear type till the day before death. Culture of the fluid might have given positive evidence earlier.

Pneumococcal meningitis as a complication of pneumonia is generally described as rare, West [44] finding no instance in two series of 100 cases. Osler,[35] however, found 8 per cent. of cases in Montreal. It may be more frequent than is supposed, as, giving rise to no symptoms, it has been repeatedly found unexpectedly post mortem.[17 37] Herringham [45] quotes six cases, in only one of which was the complication suspected during life; while the meningitis, with or without symptoms, may require microscopical examination for its identification,[17 46] which is also true for other forms of meningitis. Eyre [47] found pneumococcal meningitis 14 times in 168 cases (other than pneumonia) due to the pneumococcus at Guy's Hospital in the four years 1904–07; and Forbes [26] in the same period at Great Ormond-street found 9 cases in 142, in which lumbar puncture was performed. Even with definite meningitis lumbar puncture may give a normal fluid as already quoted,[43] Forbes [26] also finding a normal fluid in 2 cases, and only a few lymphocytes in 2 others.

Reference may be made here to an undiagnosed case, possibly a pneumococcal meningitis, where repeated lumbar puncture gave negative results, no culture being taken.

C. Y., aged 3 years, admitted as (?) meningitis was found to have empyema, which was operated upon. The meningeal symptoms became more marked with extreme restlessness and retraction, which lumbar puncture, performed 4 times, at first relieved. A large excess of clear fluid escaped at high pressure, without leucocytosis or increase in albumen. Subsequent tappings yielded a similar fluid in smaller amounts with no amelioration of symptoms; the last tapping 2 days before death giving only a few drops, unconsciousness and marked retraction being present. This association of diminishing fluid with increasing symptoms Quincke regards as pointing to interruption of the communication between brain and cord at the base of the brain. Necropsy was refused. Definite optic neuritis was not present. The temperature (104° F. on admission) fell to 100° after operation; rising again, it fell after lumbar puncture, remaining at 99–100° till 2 days before death, when it rose to 102–103°. The pulse was weak and mostly irregular and unaffected by treatment. Pneumococci were obtained in the pus withdrawn from the empyema before operation. Was it a septic meningitis with unaltered spinal fluid, probably due to interruption of the communication at the base of the brain; or a serous meningitis?

Meningitis due to the pneumobacillus.—The bacillus of Friedländer is credited with the production of meningitis by Weichselbaum and Oppenheim. The following appears to be a case due to that organism.

H. P., aged 2 months, was admitted for bronchitis. After 10 days indefinite illness, in which the symptoms appeared to be out of proportion to the physical signs, diarrhœa set in, and 2 or 3 days later,

marked head retraction with depressed fontanelle and rising temperature. Lumbar puncture gave a clear watery fluid, increased in amount, no leucocytosis, only a few lymphocytes, and apparently laked red cells being present, the temperature (105° F.) falling after it, but without relieving symptoms. One suspected a hydrocephaloid condition associated with the diarrhœa, or, having regard to the pulmonary condition, tuberculous meningitis. The fundi were normal. Death occurred 3 days after lumbar puncture, preceded by convulsions and squinting, the fontanelle remaining depressed throughout.

The spinal fluid withdrawn a few minutes after death was scanty and blood stained, with copious diplo-bacilli and a small mixed leucocytosis, mononuclears predominating. (See Fig. 3.) The organism was Gram-negative, apparently a diplo-bacillus, and bi-polar staining where stained lightly with Leishman's stain. The fluid was not cultured.

At necropsy next day the brain showed marked congestion with increased turbid meningeal effusion, but no pus. Near the Sylvian fissure were found 2 or 3 small pustules resembling tubercles, but larger and more opaque, these in smear and culture giving an organism identical with that found in the spinal fluid. Death appeared to be immediately due to a bilateral intra-ventricular hæmorrhage, apparently accounting for the blood cells in the spinal fluid. There was no sign of tubercle. I am indebted to Dr. Lindsay Milne, late of the Pathology Department, Edinburgh University, who examined the culture from the meningitis, for the following description of the organism. "A bacillus non-motile, non-sporing, Gram-negative, giving a white growth on potato, slightly coagulating milk and slightly liquefying gelatin (probably due to a slight admixture with staphylococcus) and pathogenic to mice." Unfortunately, the culture was not sent up for examination till late. Arkwright[23] has isolated a Gram-negative oval bacillus from the spinal fluid of an infant dying with meningitic symptoms, but with no macroscopic meningitis at necropsy.

Streptococcal Meningitis.

A. W., aged 9 months, with a history of diarrhœa and vague ill-health, was admitted temporarily to a medical ward late at night with epiphysitis of the lower end of the tibia. In the ward it was noticed that the child failed to notice its surroundings and meningitis was suspected. At 5 A.M. fits developed and lumbar puncture at once performed gave a large excess of turbid yellowish fluid, with high leucocytosis with over 80 per cent. mononuclears and copious typical chains of streptococci, also isolated in pure culture. (See Fig. 4.) Death occurred less than 12 hours after admission, necropsy that day revealing general purulent meningitis; streptococci were obtained in culture from the spleen, meninges, and the subperiosteal pus from the tibia. The temperature on admission was 102° F., rising to 104°, falling to 102° after lumbar puncture. As in several of these cases the liver showed fatty changes and the abdominal glands some enlargement.

Staphylococcal Meningitis.

Lumbar puncture was not performed in the case of a girl admitted moribund, with a neglected septic periostitis of the femur, septic endocarditis, purpuric rash, and purulent meningitis. Death occurred soon after admission, staphylococci being obtained in smear and culture from meninges, heart valves, spleen, and subperiosteal pus. In this case, as in the last, the meninges contained purulent effusion, distinctly yellow in the sulci, and milky over the convolutions; there was not the thick purulent muff on the surface of the arachnoid seen in pneumococcal cases.

The following was a case probably of fulminant staphylococcal meningitis. F. T., aged 6 years, was admitted to a surgical ward with fits and vomiting five days after a cerebral injury, before which he was quite well, save for multiple abscesses of the scalp, still present. A large excess of blood-stained fluid at high pressure was removed on the night of admission, containing more polymorphs than the blood contamination would account for; only temporary relief followed. Next day a similar fluid was obtained; no cocci were seen; no culture was taken. Death occurred on the third day of the illness.

At the necropsy the brain showed marked congestion and a turbid meningeal effusion; no pus; no tubercles. The pericardial sac contained an excess of clear yellow fluid, and under the epicardium were two or three very small pustules like large tubercles, which in smears and culture proved to contain staphylococcus aureus. The temperature varied between 99° and 105° F. Was this fulminant staphylococcal meningitis? Maiella[12] in experimental staphylococcal meningitis, in dogs, found that pus formation did not occur if death occurred early—within three days. Ballance[49] found this absence of pus formation in fulminant otitic meningitis (meningitis serosa maligna); and several observers also in cases of fulminant cerebro-spinal (epidemic) meningitis.

Of 6 cases not definitely diagnosed, 3 have been described under tuberculous (M. M.), pneumococcal (C. J.), and staphylococcal (F. T.) meningitis.

In R. M., dying a few hours after admission, lumbar puncture was not performed. Necropsy showed meningeal congestion and turbid effusion, no pus. It was probably septicæmia connected with a healed sore on the foot; resembling a case seen in the Edinburgh Royal Infirmary, where a Swedish sailor, dying a few hours after admission, showed nothing definite at the necropsy, but staphylococcus was obtained in culture from the blood contained in the heart and from the spleen, a small septic focus in the axilla having healed a few days before onset of symptoms.

Another case, C. McC., aged 5 years, died 15 hours after admission with persistent fits, which originated a few hours before admission with a typical epileptic fit. Lumbar puncture had no effect, giving a slightly increased fluid with small lymphocytosis. Post mortem there was no evident congestion, the brain seeming unusually dry. The ears were healthy. This appears to have been status epilepticus. Richenol and Castin[50] have reported a case in which repeated lumbar puncture produced temporary relief.

R. T., under treatment for infantile eczema, suddenly developed severe convulsions and retraction which lumbar puncture temporarily relieved, giving an excess of watery fluid, slightly blood-stained and with a slight increase in lymphocytes. The convulsions recurring soon after proved fatal, the temperature rising to 106° F. Necropsy revealed cerebral congestion and extravasation of blood into the membranes, which may have explained the blood-cells in the spinal fluid; also a much enlarged thymus. Feer,[51] who has collected over 30 cases of "eczema deaths," attributes them to status lymphaticus, which the state of the thymus in this case appears to confirm.

Several cases of meningitis were brought to hospital for the fits, and in the absence of other meningitic symptoms were sometimes sent away as epileptic or teething. This is probably not a rare occurrence, since in the Reports of a large London hospital two cases are mentioned as having been admitted for fits and discharged cured, one of which, re-admitted later, died from tuberculous meningitis, the other dying four days later in another hospital, also from tuberculous meningitis. Several cases were also mentioned as dying with fits which necropsy failed to explain.

Acute Serous Meningitis.

This series included one case apparently of acute serous meningitis.

The patient was a girl aged 1 year and 8 months. Acute meningitic symptoms, with definite optic neuritis and persistent screaming fits, were present; also the marked craving for food seen in some cerebral cases. Marked improvement followed lumbar puncture. The fluid on two occasions spurted for a considerable time, being in large excess, but otherwise normal, being devoid of cells and sterile in culture. The screaming fits and the voracious appetite persisted for a while after leaving hospital. After 2½ months lumbar puncture was again performed. The fluid again spurted, being otherwise normal. She was then a different child—bright, happy, and apparently quite well. The optic discs appeared normal, the screaming fits had practically ceased.

Acute Poliomyelitis.

Lumbar puncture in 4 cases of acute poliomyelitis gave a fluid with certain similar characters. It was increased with a small blood contamination. In 2 there was a small but definite lymphocytosis and in the other 2 the lymphocytes were increased. They all reduced Fehling's solution, but slowly. Albumin was not appreciably increased, but seemed slightly so in 2. In 1 the fluid actually spurted in the third week of the disease, and gave a culture of a Gram-negative irregularly staining bacillus. In another lumbar puncture on four occasions was similar, being more plentiful at the last tapping, three weeks after the first, and was sterile in culture. This case on admission was regarded as tuberculous meningitis, with cervical rigidity, hemiplegia, and lymphocytosis, but no tubercle bacilli were found nor the typical coagulum. Another case was very retracted and "meningitic" in the out-patient room. The largest lymphocytosis occurred in a case with no cerebral symptoms. No organisms were seen in smears. Ager[52] avers that lumbar puncture is highly beneficial and that the improvement in the later stages has been so often accelerated by it that further trial is justifiable. In the case in which the fluid spurted it was thought there was some improvement after its removal.

In diagnosis lumbar puncture is of very great importance, the one conclusive result being the identification of a causal organism. With most of the tests a negative result may be of little consequence, while positive results are of value, as they confirm one another and the clinical evidence. Therapeutically lumbar puncture has been disappointing, partly because too much was expected from it. Cures have been attributed to its repeated performance in various forms of meningitis, even tuberculous, with or without other treatment. In microbial meningitis it may do good by removing organisms and their toxins, and by removing an inert fluid with practically little or no opsonic and agglutinative properties and thereby causing the exudation of fresh fluid having greater protective powers.[34] A vaccine may be prepared from the fluid or antiseptic injection employed. There is, however, the fact that many cases are too *foudroyant* to allow of opportunity for treatment, while others are so latent as to escape suspicion of the real nature of the condition until past interference. Meningitis associated with otitis often best lends itself to operative interference. The septic focus having been removed and the meninges drained, a cure has several times resulted. Encouraging results are reported as following the administration of urotropine[53] in meningeal infection. The drug is said to be excreted in the spinal fluid in half to one hour after ingestion and to exert a marked antibacterial effect. It was first employed in a case of cerebro-spinal fistula, following trephining for cerebral tumour, in which the discharge became purulent. After the administration of 30 grains daily for a week the temperature became normal and recovery ensued. Experiments made in animals confirmed its value, and its prompt administration in all cases where meningitis is a possible complication is advised.

I am much indebted to the staff of the Queen's Hospital for Children for permission to publish this account of cases which were in their wards.

Carshalton.

TWO NOTES ON STERILISATION OF THE SKIN BY THE USE OF AN ALCOHOLIC SOLUTION OF IODINE.

BY HERBERT F. WATERHOUSE, M.D., C.M. EDIN., F.R.C.S. ENG.,

SURGEON AND LECTURER ON SURGERY, CHARING CROSS HOSPITAL; SENIOR SURGEON, VICTORIA HOSPITAL FOR CHILDREN; MEMBER OF THE COURT OF EXAMINERS, ROYAL COLLEGE OF SURGEONS; EXAMINER IN SURGERY, UNIVERSITY OF LONDON;

AND

W. STEPHEN FENWICK, M.S., M.B., B.SC. LOND., F.R.C.S. ENG.,

SURGICAL REGISTRAR, CHARING CROSS HOSPITAL.

Note by H. F. WATERHOUSE.

FOR several years I have employed iodine as an antiseptic for the sterilisation of catgut, and have found that soaking the catgut, as it comes direct from the manufacturer, in a solution of 1 part of iodine to 500 of equal parts of rectified spirit and water for a period of one week has invariably proved sufficient to render the catgut sterile, and thus safe for surgical purposes.

I have on several occasions in years past attempted to make use of the tincture of iodine as an adjuvant to the sterilisation of the skin after a preliminary careful and thorough washing and scrubbing with soap and water, and the employment of an antiseptic solution. To my disappointment the results were not superior to those obtained by the ordinary methods, and I had begun to fear that for some reason iodine in solution was unsuitable for sterilisation of the skin. It was not until my attention was drawn to the fact that this method failed for the reason that the water used in cleansing the skin caused the epithelial cells to swell and thus prevented the antiseptic from penetrating deeply between them and into the ducts of the sebaceous and sweat glands that I realised that the preliminary washing with soap and water was not only unnecessary but even harmful.

Since abandoning the use of soap and water and contenting myself with painting the skin with an alcoholic solution of iodine my results have been nearer perfection as regards the absence of sepsis than any I have previously obtained. I have myself made use of the method in 150 cases, with the result that 149 healed entirely by first intention. In one case only was there any sepsis, and even in this instance (a radical cure of inguinal hernia) when the sutures were removed on the eighth day the wound was healed except in its outer three-quarters of an inch, where its margins gaped slightly. At the next dressing three days later a small quantity of pus was found, which on bacteriological examination, gave a pure culture of staphylococcus albus. This slight suppuration soon ceased and the patient was discharged at the end of three weeks with the incision soundly healed. Of the 150 cases, 110 occurred in my wards at Charing Cross Hospital; they were all under the daily observation of Mr. W. S. Fenwick, who has been kind enough, at my request, to add a note concerning them to this communication. Of the remaining cases, 22 were in my ward at the Victoria Hospital for Children, and for information regarding them I am indebted to the house surgeon, Dr. J. B. Molony. 18 occurred in my private operative practice. I would desire to express my obligations to Miss Enid Stockdale, the sister in charge of my wards at Charing Cross Hospital, and to my house surgeons, Dr. E. H. Hugo, Mr. Norman G. H. Salmon, and Dr. R. H. H. Jolly, for much help willingly rendered in this investigation. Of the above patients, death occurred in one only—viz., in the case of a woman, aged 50 years, sent to me by my colleague, Dr. Victor Corbould, with advancing thrombo-phlebitis of the left internal saphena vein. After the incision requisite for the removal of the inflamed vein had healed, the patient was on the afternoon of the day of her death seen by Dr. Corbould and myself in the ward. She stated that she felt quite well and almost able to get out of bed. At 8 P.M. she died suddenly after four or five minutes of intense dyspnœa. A confident diagnosis of pulmonary embolism was made, but a careful necropsy by Dr. D. Forsyth failed to reveal an embolus. It showed, however, what we had never suspected—an advanced stage of contracted granular kidneys. It is worthy of note that on examination prior to operation no albumin was found in the urine, but it must be admitted the urea had not been estimated. The mode of death in this case with intense and sudden dyspnœa remains to me a mystery.

For the first 26 cases a solution of in some cases 8 and in others 6 per cent. of iodine in rectified spirit was employed. It was painted on the skin of the operation area two hours prior to bringing the patient into the theatre. As soon as the skin had dried it was covered by a sterilised towel, which was bandaged on. Whilst the anæsthetic was being administered a second application of the 8 or 6 per cent. solution was made, and the operation was commenced two or three minutes later. It soon became apparent that these solutions were unnecessarily strong. Three patients complained that the smarting pain was severe after the first application. In all three the skin of the neck was the area involved. The solution was, so the theatre sister informed me, very destructive to the towels, burning holes in them. I therefore determined to employ a weaker solution and decided upon 2 per cent. of iodine in rectified spirit. This has proved entirely satisfactory and has given risen to no single complaint of smarting. For the first 25 cases in which the weaker solution was used I thought it well to employ three applications of the iodine paint in place of two of the stronger fluid. The first application was made two hours, the second one hour prior to operation, and the third on the operating table.

Recently we have omitted the intermediate painting. The 2 per cent. solution appears to me to be just as trustworthy as the 6 per cent., and it has not caused any complaint of smarting or got me into trouble through the destruction of towels in the operating theatre.

It is worthy of note that the staining caused by the iodine solutions is at once removed by soaking the towel in a solution of carbolic acid (2½ per cent.).

A matter of real importance is that the iodine should be dissolved in rectified, not in methylated, spirit. This I learned at the expense of considerable suffering to my assistants as well

as to myself. When first we employed the 2 per cent. solution it was ordered to be dissolved in rectified spirit. Someone well aware that it was used for external application only, in the interests of economy employed methylated spirit without informing me of the change. To my astonishment the weaker solution proved painfully irritating to the conjunctiva, even some minutes after its application. The suffering and lacrymation were so intense that I had contemplated abandoning the method when I learned of the substitution of methylated for rectified spirit, and insisted on the employment of the latter, since which the trouble has entirely disappeared.

On a few occasions tincture of iodine was employed. This, as also a 2 per cent. solution of iodine in chloroform, gave results quite similar to the 2 per cent. alcoholic solution.

In future I shall always employ a 2 per cent. solution of iodine in rectified spirit. I shall paint this solution on the skin two hours prior to the operation, the preliminary shaving and any necessary washing of the skin having been performed some time earlier in order to allow the skin to dry. I shall then for greater security in important cases repeat the painting one hour later, though I hardly deem this intermediate application necessary. The last painting will be done on the operating table. A small flat painter's brush answers admirably. It need only be sterilised if the surgeon is to handle it on the operating table. In general, a dresser or a nurse will do the painting while the surgeon is washing his hands.

In radical operations for hernia in small boys it is always difficult to keep the penis under cover, and in such cases I invariably paint the whole organ and scrotum with the 2 per cent. iodine solution and leave them uncovered with a full sense of security.

It must be admitted that the iodine solution increases the vascularity of the skin and subcutaneous tissues and that the superficial hæmorrhage is greater than normal. Further, it seems certain that the edge of the knife becomes dulled sooner than is generally the case, and the skin appears distinctly hardened. Dr. Molony considers that in young children collodion applied to the incision after suture is apt to cause redness of the skin and irritation, and I am inclined to agree with him that its use is inadvisable.

My house surgeons, who have used this method in a large number of cases in the out-patient and casualty departments, are in general agreement that whilst the results obtained by them have been very satisfactory they have not been equal to those found in the case of in-patients. The reason doubtless is that in the hurry of out-patient minor operations a sufficient time may not intervene between the two applications of the iodine solution; thus it may be reduced from two hours to 10 or 15 minutes. A case typical of the value of the method in out-patient practice may be mentioned.

A labouring man with more than ordinarily dirty feet had a painful hammer-toe on each foot. My house surgeon painted the parts with the iodine solution without the use of soap and water and repeated the application half an hour later. The offending toe of each foot was amputated in the out-patient operating room and the wounds dressed. The patient returned a few days later with both incisions healed by first intention. This case well exemplifies the time-saving value of the method.

In certain cases in which it appeared probable that the skin incision might be infected by discharge from a hollow viscus—e.g., colotomy and cholecystostomy—it was found advisable to paint the line of incision with the 2 per cent. iodine solution each time the wound was dressed. The incision was then covered by dry cyanide gauze. Though this frequent painting might be carried out twice daily for from 4 to 6 days no interference with the healing of the incision was noted. This method I can cordially recommend.

A notable advantage of the iodine method is the fact that the whole preparation is carried out only two hours prior to the operation. One of my private nurses informs me that in her experience a patient prepared for an amputation of the breast the evening prior to operation hardly obtains any sleep. The scrubbing of the skin, the employment of the necessarily irritating antiseptic, and the bandaging are jointly responsible for this, and the dressing is a constant reminder of what is to come in the morning. With the iodine method the patient's preparation only begins in the morning and she therefore has nothing but the dread of the operation to interfere with sleep.

In conclusion, I may add that I am so satisfied with the iodine method that I intend to use it in future as a routine measure and will continue to do so until a better is discovered.

Note by W. STEPHEN FENWICK.

In adding a list of the 110 cases which occurred in Charing Cross Hospital I am able to endorse most emphatically all that has already been said by Mr. Waterhouse both as regards the simplicity and the efficacy of the iodine method of skin preparation. From the point of view of the dresser it is a boon, owing to the great saving of time; moreover, the patient is spared the worry and tedium—to make no mention of actual pain—that the ordinary method entails.

It is worthy to note that a few of the cases recorded below were more or less septic at the time of operation—e.g., excision of a rodent ulcer and excision of a strawberry tumour of the umbilicus with a markedly eczematous condition of the surrounding skin—yet healing *per primam* occurred.

All are aware of the difficulty in sterilising the skin immediately adjacent to a septic focus; the iodine method would appear to overcome this difficulty.

On examining the wounds at the eighth day I was struck by the entire absence of moisture around the stitches in the skin. In cases prepared by the ordinary method it is quite common, even where there is no other evidence of infection, to find, when stitches are removed at the end of a week, a minute bead of pus (usually giving a culture of staphylococcus albus) at one or more of the stitch openings.

The cases were as follows:—

Herniotomy (femoral and inguinal)	22 cases.
Appendicectomy	16 ,,
Excision of glands in neck and axilla	9 ,,
Excision of varicose veins	8 ,,
Amputation of breast and excision of breast adenomata	6 ,,
Gastro-enterostomy	5 ,,
Cholecystostomy	4 ,,
Partial thyroidectomy and enucleation of thyroid adenomata	4 ,,
Radical cure of hydrocele	3 ,,
Excision of lipomata	3 ,,
Amputations (leg and fingers)	2 ,,
Colotomy	2 ,,
Excision of hip-joint	2 ,,

And one each of the following: hysterectomy, nephrolithotomy, laparotomy, radical cure of congenital umbilical hernia, excision of sarcoma in axilla, wiring fractured olecranon, wiring fractured patella, excision of rodent ulcer, excision of shoulder-joint, suture of median nerve, orchidopexy, excision of strawberry tumour of umbilicus, excision of branchial cyst, suture of tendons, castration, evacuation of psoas abscess, ovariotomy, and excisions of sarcoma of thigh, of needle in hand, of sebaceous cyst, of fibroma, of thyroglossal cyst, of phalanges, and of nævus.

Comparing the iodine method with that still in common use, I am convinced that the former is more easily carried out, takes less time, is less unpleasant to the patient, and gives better results than the latter.

CHELSEA HOSPITAL FOR WOMEN.—In the thirty-ninth annual report of the council of this institution, which was submitted to the recent annual meeting of the governors, it is shown that the outstanding features of the past year's work have been a considerable increase in the number of the in-patients (801 as compared with 720 for 1908) and a deficiency of income of £1000. The chairman, in moving the adoption of the report, stated that although the expenditure on medical requirements, and especially on appliances for sterilisation, had been increasing, economy in other directions had reduced the average weekly cost per patient from £2 6*s.* 2*d.* of 1908 to £2 0*s.* 11*d.* The deficiency of £1000 was largely due to absence of legacies; the annual subscriptions owing to the death of old friends had also fallen off. Fortunately, he said, the hospital would shortly receive from the trustees of the Zunz Bequest a sum of £2000, and hoped that this generous recognition of the hospital's work, like the recent munificent donation by Lady Tate of £1000 to endow a bed, would encourage other benefactors to come forward. The chairman also alluded to the fact that 113 hysterectomies for the removal of fibroid tumours had been made during the year without a death. Contributions should be sent to the treasurer, Mr. H. E. Wright, or to the secretary, Mr. H. H. Jennings, at the Hospital, Fulham-road, S.W.

A CASE OF

EMBOLISM OF THE ABDOMINAL AORTA WITH MITRAL STENOSIS AND THROMBOSIS OF THE PULMONARY VEINS; DEATH; NECROPSY.

BY SIDNEY P. PHILLIPS, M.D. LOND., F.R.C.P. LOND.,
SENIOR PHYSICIAN TO ST. MARY'S HOSPITAL AND THE LONDON FEVER HOSPITAL.

THE patient, aged 39 years, began to be troubled by a feeling of shortness of breath in January, 1909; after attending as an out-patient till the following November this increased and he had to give up work and lie up at home for five weeks. He then came under my care at St. Mary's Hospital on Jan. 10th, 1910. There was no history of rheumatism, or of syphilis, or of any illness. The patient was a strongly-built, fairly nourished man and the only complaint he made was of shortness of breath, even while he was lying quietly in bed and the respirations were only 20 per minute. There was slight cyanosis. I could find no defect in the lungs. His pulse, about 70 a minute, was feeble and at times irregular; over the apex beat of the heart, which was situate just outside the left nipple line, the first sound was short and sharp, and the second sound was usually duplicated, but a series of beats often occurred in which it was not duplicated and at other times a series of beats in which no second sound was audible. A presystolic rumble was present, but I never felt any thrill. There was no dropsy and no evidence of tricuspid regurgitation. On the 12th he had sudden severe pain in the lower part of the abdomen, persisting throughout the night, with vomiting of all food taken, and in the early morning of the 13th there was pain in the left leg. These pains had passed away when I saw him later on the same morning; the skin over the abdomen generally was very hyperæsthetic, but there was no distension or rigidity of the abdomen. On the same afternoon sudden pain occurred in the loins and the urine passed soon after contained a slight cloud of albumin which had up to that time been absent. There was no hæmaturia. The temperature rose in the evening from normal to 100·8° F. During the next few days the patient was free from pain and seemed much better, the pulse was 48 to 60 a minute, the presystolic murmur was more definite, a trace of albuminuria persisted. On the 24th sudden intense pain came on in both legs below the knees and they became cold and blanched; there was another attack of intense pain in the abdomen and the patient became pinched in the face and looked very ill. The pain in the legs continued severe, and there was a complete loss of sensation to touch and to pin-pricks below the knees, but no evident loss of motor power. The skin of the legs and feet became cold and clammy with hard patches of venous stasis. There was very faint pulsation in the dorsalis pedis artery and the posterior tibial arteries, but the femorals could be felt to pulsate below Poupart's ligaments. The abdomen became very distended, tense, and tender. The temperature, normal or subnormal since the 16th, fell to 96° or 97°. There was little alteration in the heart signs except extreme feebleness of the right ventricle sound. Death occurred on the 25th.

Post-mortem examination by Dr. B. H. SPILSBURY.—The mitral orifice barely admitted the tip of the little finger and was slit-like in character. The cusps were thickened and fused together with some calcification. No recent endocarditis was present. The left ventricle was slightly dilated. The tricuspid orifice admitted the tips of three fingers. The wall of the right ventricle was much hypertrophied. The aorta was normal, but at its bifurcation was a mass of dark-red blood-clot which completely blocked the orifices of the common iliac arteries and extended along them and the external iliac and femoral arteries as far as the origin of the profunda arteries on both sides. The blood-clot occupying these vessels was everywhere dark and friable; it was slightly adherent to the vessel walls above but not at all below. Both lungs showed some hypostatic congestion, but there were no infarcts in them or inflammatory consolidation. In both kidneys and in the spleen were several recent large hæmorrhagic infarcts; some of these in the kidney had a dull white uniform colour with an hæmorrhagic border, others were of a dull terra-cotta colour. The lower part of the small intestine showed areas of greenish discolouration of the wall, due, it was found, to a long, firm, dark blood-clot in one of the branches of the superior mesenteric artery; it filled the vessel above and had a conical termination below; the last two feet of the small intestine were normal.

Subsequent dissection and microscopic examination showed in the tributaries of the pulmonary vein in the right lung numerous small yellow areas of degeneration of their inner surfaces; some of these veins contained small masses of dark and firm clot. Microscopically some of these tributaries showed fibrous thickening of the tunica intima; some were completely filled with pale thrombus which was adherent to the walls and which was undergoing organisation, and in these areas the walls of the veins were extensively vascularised. The thrombi were in places invaded by organisms. There was no inflammatory change in the surrounding lung tissue.

Remarks.—The association between mitral stenosis and occlusion of the abdominal aorta is well recognised; thus of 54 cases of aortic occlusion verified by post-mortem examination, of which Dr. W. H. Welsh collected the records,[1] 34 per cent. were in patients who had mitral stenosis. In some of these cases there was no difficulty in attributing the occlusion of the aorta to embolism, there being present recent or ulcerative endocarditis or clots within the heart cavities, from which emboli could have originated. But in the great majority of the cases there were no such lesions and no source from which an embolism could have started was detectable, and it remained doubtful whether the occlusion of the aorta arose from embolism or from thrombosis. This was so in the present case, and until Dr. Spilsbury's careful examination and dissection revealed the changes above described in the pulmonary veins.

The symptoms during life and the blocking of many arteries found at the post-mortem examination in the present case pointed strongly to the occlusion of the aorta being due to embolism and not to thrombosis, though probably secondary thrombosis took part in making the occlusion complete. And presumably the emboli arose from the clots found in the pulmonary veins. Very possibly this was the case in some of the other recorded cases of mitral stenosis and aortic occlusion in which no source for embolism was found, but in which the condition of the pulmonary veins was not investigated or recorded, for, as Dr. Welsh observes, the reports of many of them are imperfect or defective.

Among the points of interest in this case are the following. 1. The changes in the pulmonary veins. It has been pointed out by Sir James Barr that it is especially in cases of mitral stenosis that atheroma and thickening of the pulmonary veins arise. Such changes occurred in this case with formation of clots in the smaller pulmonary veins, and it is especially in cases of mitral stenosis such as this, occurring in a strong healthy man in whom tricuspid regurgitation was staved off by very considerable hypertrophy of the right ventricle, that the pressure in the pulmonary veins must be much increased and that changes in the walls of the pulmonary veins might be most expected. 2. The symptoms of the mitral stenosis. There was no discomfort about the heart region and much less irregularity and disturbance of its action than occurs in many cases of mitral stenosis, and there was no evidence either during life or after death of tricuspid regurgitation or of any affection of the lungs. Nevertheless, throughout the whole year of his illness, the one symptom of which the patient complained and which made him give up work, was a sense of shortness of breath, and this persisted while he was at rest and without any increase in the number of his respirations. It seems probable that this shortness of breath was due, in part at any rate, to the changes going on in, and to the thrombosis in, the pulmonary veins. 3. The symptoms arising from embolism of the aorta. As in other recorded cases, there were sudden attacks of intense acute pain in the abdomen and in the limbs, with changes in the latter indicative of impeded arterial blood-flow. That gangrene did not occur was only because the patient died so soon. It was noticeable that though there was complete

[1] Allbutt and Rolleston's System of Medicine, vol. vi., p. 273. first edition.

anæsthesia in the lower limbs with intense pain there was not, as in some recorded cases, any loss of motor power. Although there were many emboli in the kidney, there was no hæmaturia and but a slight cloud of albumin in the urine, and though the intestine supplied by the blocked mesenteric artery was tending towards gangrene no melæna occurred.

Upper Brook-street, W.

A CASE OF BILE-PRODUCING PRIMARY MALIGNANT TUMOUR OF THE LIVER ("MALIGNANT ADENOMA"),

WITH REMARKS ON THE CELLS OF MALIGNANT TUMOURS RETAINING SOME OF THE METABOLIC OR OTHER FUNCTIONAL CHARACTERISTICS OF THE CELL TYPE FROM WHICH THEY ARE DERIVED.[1]

BY F. PARKES WEBER, M.D. CANTAB., F.R.C.P.,
PHYSICIAN TO THE GERMAN HOSPITAL, LONDON.

THE patient, a man, aged 69 years, was admitted into the German Hospital on Jan. 27th, 1910. He said that he had enjoyed good health and gave no history of previous illnesses of importance. But since the summer of 1909 he had suffered from increasing debility with loss of flesh. He did not, however, consult a medical man until six weeks before admission, when he complained of pain and swelling in the abdomen. In the hospital the patient was found to have ascites; the liver could be felt enlarged and hard, its surface somewhat uneven, and its lower edge reaching to the umbilical level. The spleen could not be distinctly palpated but the splenic dulness was enlarged. The patient's temperature was slightly above the normal but never as high as 100° F. The pulse was about 80 to 90 per minute. Although there was no obvious jaundice in the skin or conjunctivæ a trace of bilirubin was detected in the urine, which likewise contained a little albumin. The patient died on Feb. 3rd, 1910.

FIG. 1.

Photomicrograph (× 97) of the border of one of the tumour nodules in the liver. The new growth is on the right, the liver tissue on the left.

Necropsy.—At the post-mortem examination the peritoneal cavity was found to contain much ascitic fluid mixed with blood, intraperitoneal hæmorrhage having evidently taken place from a vein passing over a large mass of new growth in the right lobe of the liver.

The liver (weight 89 ounces) was much enlarged and had an uneven surface owing to the bulging caused by the presence of multiple tumours. There was no perihepatitis. The gall-bladder and extra-hepatic bile-ducts were free. The extra-hepatic blood-vessels were not thrombosed. On section the organ was seen to be moderately cirrhotic, but to consist chiefly of rounded nodules or masses of new growth, varying from the size of a pea to double the size of a medium apple. The largest mass, in the right lobe, might possibly have been the primary growth. The tumours were almost entirely necrotic, having been transformed into a pulpy substance ("*purée cancéreuse*"), coloured greenish or yellow by the bile. In fact, nearly the whole of the liver substance was replaced by these pultaceous masses, somewhat of the consistence of mashed potato. It is quite possible that some of the pultaceous masses included necrotic liver tissue as well as necrotic new growth. The original cirrhotic liver substance was still fairly well preserved at the margin of the left lobe. In addition to the appearances already described there were a few hæmorrhages.

The spleen (weight 15 ounces) was enlarged and enclosed in a greatly thickened capsule, evidently the result of old perisplenitis; in fact, the spleen might be termed a "Zuckergussmilz," just as the German term "Zuckergussleber" has been applied to livers the capsules of which are greatly thickened from old perihepatitis.

After a careful examination no evidence of new growth could be found elsewhere than in the liver, with the exception of a single cherry-sized tumour nodule (evidently metastatic) in the left lung. Macroscopic and microscopic examination of the rectum showed the presence of hæmorrhoids, but not of any new growth. The prostate gland was likewise examined macroscopically and microscopically for evidence of new growth, but with negative result. The heart (weight 8½ ounces) was hypoplastic, and the pericardial surfaces were adherent from old pericarditis. There were pleuritic adhesions on both sides of the chest. The kidneys (weight of both together 9 ounces) showed a little old interstitial fibrosis and a condition of cloudy swelling. Nothing of special interest was discovered in the pancreas, adrenals, stomach, or rest of the alimentary canal. The lymphatic glands (microscopic examination) were apparently not infiltrated with new growth. I have to thank my house physician, Dr. G. Dorner, for his great help in the examination of the case.

FIG. 2.

Tubular columns of tumour cells enclosing inspissated bile. From the same section as Fig. 1, but under higher magnification.

Microscopic examination of the liver.—The minute non-necrosed nodules of new growth (Fig. 1) consist of cells more or less resembling those of the hepatic parenchyma and showing a marked "trabecular" arrangement (the "*épithéliome trabéculaire*" of Hanot and Gilbert[2]), that is to say, they form tubular columns of cells more or less imitating the columnar arrangement of the liver cells in the normal hepatic acini. The columns in the new growth are, however, much thicker than the normal columns of liver cells, and are more irregular in their arrangement, and the tumour cells stain slightly more deeply (hæmatoxylin and eosin) than the normal liver cells. Some of the tubules contain inspissated bile (Fig. 2), which is coloured dark green in the sections stained by hæmatoxylin. In some parts the columns

[1] A paper read before the Pathological Section of the Royal Society of Medicine on March 15th, 1910.

[2] V. Hanot and A. Gilbert: Études sur les Maladies du Foie—Cancer, &c., Paris, 1888, p. 41.

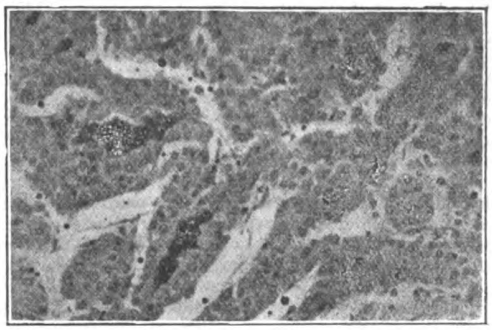
of cells in the new growth are separated from each other by considerable spaces containing connective-tissue shreds. These "intertubular" spaces were doubtless orignally much smaller and were occupied by imperfectly formed blood-vessels, but have become enlarged during the process of preparation of the sections. Some portions of the new growth (probably on the point of becoming necrotic) show hæmorrhagic and small-cell infiltration.

The tumour capsules, if any can be said to exist, are formed by the compressed surrounding tissue. The liver substance shows small-cell infiltration, chiefly of interacinous distribution, and a moderate degree of cirrhosis; there are likewise scattered hæmorrhagic areas.

Remarks.

The case is doubtless one of a form of primary carcinoma of the liver in which the tumour cells are derived from the glandular bile-secreting cells of the hepatic parenchyma. After a careful search (partly microscopical) no primary growth could be discovered in the stomach, rectum, intestines, prostate, &c.[3] The primary hepatic nature of the growth is, moreover, abundantly confirmed by the appearance of the tumour cells and by their ("trabecular") arrangement in tubules, some of which enclose inspissated bile. The malignant nature of the tumours is proved not only by their great development in the liver and by the necrotic changes they have undergone there, doubtless due to involvement of the hepatic blood-vessels, but also by the presence of a secondary nodule in the lung, which, however, I regret was unfortunately not examined microscopically.

The disease in question has been variously termed "primary carcinoma with cirrhosis" (Hanot and Gilbert), "cirrhosis maligna," or, as Dr. H. D. Rolleston (on the analogy of carcinoma of the stomach supervening on chronic gastric ulcer and primary carcinoma of the breast supervening on chronic interstitial mastitis) prefers to call it, "cirrhosis carcinomatosa." The tumour has also been spoken of as "hepato-adenoma" (Lancereaux), "adeno-carcinoma of the liver," and "malignant adenoma of the liver" (H. Ribbert). By analogy with terms which have been suggested or employed to designate primary tumours of other organs (e.g., "hypernephroma," and possibly also "myeloma" and "splenoma") the term "hepatoma"[4] or "malignant hepatoma" might also be adopted for these primary carcinomata of the liver. If, however, this principle of nomenclature were to be carried further the text-books would soon be containing descriptions of "mastoma," "nephroma," "pancreatoma," and possibly also of various forms of "gastroma" and "enteroma."



Do the cells of malignant tumours retain some of the metabolic or other functional characteristics of the type of cell from which they are derived? In the present case the tumour-cells were certainly secreting bile (or at all events bile-pigment) in some parts, as shown by the inspissated secretion enclosed within many of the tubular columns of the growth. It is quite possible that a stage of simple adenoma or "nodular hypertrophy" of liver cells precedes the development of the malignant adenoma (primary carcinoma) of the liver cells, and it might perhaps be objected that bile is only secreted by the cells during the "nodular hypertrophy stage," but that when the stage of malignancy is reached the tumour-cells are no longer bile-producing. It is quite likely, indeed, that the power of secreting bile gradually diminishes when the tumour becomes malignant, and in this connexion I am exceedingly sorry that the metastatic tumour in the lung of the present case was lost. However, Dr. Rolleston[5] figures a section, which he has kindly allowed me to copy (Fig. 3), from a case of hepatic "carcinoma with cirrhosis" in which the tubules of the growth contain still more inspissated bile than in the present case, and H. Ribbert,[6] in a recent article on "malignant adenoma" of the liver, refers to bile production by the tumour cells as a pathological distinction of great importance for the recognition of this class of new growths.

In this connexion one may call to mind that some of the primary tumours of the bone-marrow termed "multiple myeloma" (whose malignancy is evidenced by the bone-erosion which they cause, and occasionally by involvement of lymphatic glands) have been found to consist of cells whose cytoplasm contains granules more or less resembling those in normal myelocytes.[7] From the same point of view it is likewise interesting that certain tumours of the hypernephroma type in children have apparently given rise to a precocious plethoric type of obesity (or to excessive growth of the skeletal muscles) and premature sexual development.[8] I need scarcely refer to the well-known (though rare) metastatic tumours (in bones, &c.) of typical thyroid structure. One may furthermore instance the well-known production of "cell-nests" ("epithelial pearls") in some of the metastases from squamous cell carcinomata of the skin and tongue as well as in the primary growth.

Perhaps improved methods of chemical and physiological histology will ultimately show that the cells of certain primary malignant tumours of the breast, pancreas, and other organs do retain some of the functional characteristics of the cells of the organ from which they are derived.

Harley-street, W.

FIG. 3.

Photomicrograph (× 220) from a case of hepatic "carcinoma with cirrhosis" illustrated by Dr. Rolleston.

[3] In all apparently primary cancers of the liver the importance of careful search for a possible primary growth elsewhere is well known. In regard to examination of the rectum it is also a recognised fact that small tumours of the rectum may give rise to large secondary growths in the liver. Thus, in 1904 a man (aged 50 years) under my care died from secondary carcinoma of the liver. The organ in question was of immense size and weighed 12½ kilogrammes—that is to say, over one-fifth of the total weight of the body (60½ kilogrammes)—whereas the primary growth in the rectum formed a projecting lump of the size only of a large cherry.

MUNICIPAL TECHNICAL COLLEGE, BRIGHTON.—A new departure in the work of the Brighton Technical College was made on the evening of April 5th, when Dr. F. G. Bushnell commenced a course of lectures on bacteriology. The course is primarily intended for students of public health, but has been arranged so as to be also a suitable adjunct to the study of dental surgery, veterinary medicine, agriculture, and pharmacy. The course is illustrated with lantern slides and demonstrations.

THE METROPOLITAN PUBLIC GARDENS ASSOCIATION.—This association, formed in the year 1882 with the object of providing breathing spaces and resting places for the old and playgrounds for the young in the midst of densely populated localities, shows in its twenty-seventh annual report a record of work which must play an important part in conserving the health of the inhabitants of the metropolis. Not the least useful work of the association is the careful watch which it keeps over measures introduced into Parliament and its active opposition to Bills containing clauses which endanger existing open spaces. During the past year in connexion with kindred bodies it secured a clause in the Town Planning Bill for the protection of commons and open spaces. The association is under the patronage of His Majesty the King and the Prince of Wales. To the report is added an appeal by the chairman, the Earl of Meath, for additional financial support.

A CASE OF EPIDEMIC CEREBRO-SPINAL MENINGITIS, TREATED BY FLEXNER AND JOBLING'S SERUM; RECOVERY.[1]

BY JOHN J. WEAVER, M.R.C.S. ENG., D.P.H. CANTAB.,
MEDICAL OFFICER OF HEALTH, SOUTHPORT.

With notes by N. PERCY MARSH, M.B. Lond., *Physician to the Liverpool Infirmary for Children.*

A GIRL, 16 years of age, was admitted into the Southport Infectious Diseases Hospital on Friday, Nov. 26th, 1909. On Friday, Nov. 19th, seven days before admission, she was at school and well. On the following evening (Saturday) she complained of slight headache, which, however, soon passed off. On Sunday she ate a good dinner. When in church at night she was suddenly attacked with pain at the back of her neck and in her legs. On returning home she is said to have had a rigor, followed by a restless night. On Monday, the 22nd, she had headache, pains all over her body, vomiting, and rigor, followed again by a restless night. On Tuesday the headache and vomiting continued, and there was slight sore-throat. Slight stiffness of the neck was noticed. The temperature was 103° F. There was no sleep at night. On Wednesday the stiffness of the neck was more marked. Vomiting had ceased. Temperature 103°. Very restless; no sleep. On Thursday, the day before admission to hospital, her neck was rigid. The temperature was 103°. There was retention of urine and a catheter was passed. The restlessness continued; no sleep.

On Friday I was asked to see the patient at her own home in consultation with her own medical man with a view to the case being removed to hospital as possibly a case of typhoid fever. At that time the symptoms pointing to typhoid fever were the headache, the furred tongue, the continued rise of temperature, some doubtful "spots" on the abdomen, and an indefinite history of general ill-health for some few weeks before the actual onset of the present illness. There was, however, no diarrhœa, no enlargement of spleen could be detected, and the aspect of the patient, including the slight retraction of head, which, however, at this time was not very marked, was not quite that of typhoid fever. However, as the patient could not be satisfactorily nursed at home, I agreed to her removal to hospital.

On admission at the hospital the same day (Nov. 26th) the patient had dull aching, but not very acute, pain in the head. She was drowsy and apathetic, but answered intelligently any questions put to her. The tongue was furred. The retraction of the head prevented her lying on her back, and the muscles of the back of the neck were very tender to touch. The temperature was 101°. The bowels were constipated. Widal's reaction was negative. Up to this point, beyond the doubt about the case being one of typhoid fever, a definite diagnosis had not been made. On the chance of the pain in the muscles of the neck being of a rheumatic character a few doses of salicylate of soda and bicarbonate of potash were given, but without any improvement. The patient continued the next two days much about the same, the temperature reaching 103° on the 28th, and at no time falling below about 100°.

On the afternoon of Tuesday, the 29th, three days after admission, the patient had a severe rigor, and it was the occurrence of this rigor which definitely decided me in favour of the case being not typhoid fever but probably epidemic cerebro-spinal meningitis. Knowing that Dr. Percy Marsh of Liverpool was much interested in these cases, I telephoned the following day to his house in Liverpool, and found that at that moment he was in Southport in consultation with Dr. D. M. Hutton, and after I had found him here he kindly went with me to the hospital. A lumbar puncture was made and 30 cubic centimetres of turbid cerebro-spinal fluid were drawn off. On standing a thick deposit settled down out of the fluid at the bottom of the test-tube, about half to one inch in depth. Kernig's sign was well marked. Later in the evening, on obtaining Flexner and Jobling's serum from Liverpool, I injected 30 cubic centimetres of it by lumbar puncture. The fluid drawn off was reported on by Dr. O. T. Williams of Liverpool as follows: "Purulent. The stained film shows polymorphonuclear leucocytes, with intra- and extra-cellular organisms—diplococci only. No other organisms found in film. Cultures on nasgar medium give typical growths in pure culture of the meningococcus—which are Gram-negative. No other organisms grown. A typical case of meningococcic meningitis."

On each of the next four days cerebro spinal fluid was withdrawn and serum injected, and then after one day's intermission a final dose of 15 cubic centimetres of serum was injected on the sixth day. Following the first injection there was immediate improvement in the patient. The following day the retraction of the head was so much better that the patient was able to lie on her back without discomfort. There were no further rigors and the temperature gradually fell until, by the eighth day after the first injection, it was normal and remained so. The fluid drawn off became daily much less turbid until, on the last date of puncture, it was as clear as water. Microscopic films showed each day less turbidity and slighter purulent deposit, also degenerated leucocytes, and the organisms became difficult to find, and finally disappeared altogether. The girl was kept in hospital for the sake of quiet and rest until Dec. 28th and then discharged. At the time she showed no effects of her illness, except that the knee-jerk on the right side was absent and on the left very slight. She has since remained well.

Remarks by Dr. PERCY MARSH.[2]

Previous to the use of Flexner and Jobling's serum the mortality from cerebro-spinal (meningococcic) meningitis varied between 70 and 80 per cent., and in children it was 86 per cent; in October, 1909, Flexner tabulated 712 cases, which had been treated with the serum, of which 488 recovered and 224 died, giving a mortality of 31·4 per cent. (See Table.) A study of these tables emphasises strongly the importance of early diagnosis, for out of 241 who received the serum during the first three days of illness only 61 died, or 25·3 per cent., whereas of 223 who were not injected until after the seventh day 94 died, or 42·1 per cent.

Table showing Cases of Epidemic Cerebro-spinal Meningitis treated with Flexner and Jobling's Serum.

Ages (years).	Total number of cases.	Recovered.	Died.	Mortality (per cent.).
1- 2	104	60	44	42·3
2- 5	112	82	30	26·7

The serum, which is obtained by immunising the horse with many strains of the organism, is bactericidal and only slightly antitoxic, and therefore it must be injected directly

[1] Reported at a meeting of the Southport Medical Society on Feb. 23rd, 1910.

[2] Being an Abstract of Remarks made by Dr. Marsh at the Southport Medical Society.

into the spinal canal. It is advisable, therefore, to use a needle when doing a lumbar puncture which accurately fits a syringe which will hold 15 cubic centimetres, so that if turbid fluid is withdrawn all that is necessary is to warm the serum to the body temperature, and inject slowly into the canal after removing the fluid. It is always advisable to remove if possible at least 30 to 40 cubic centimetres of cerebro-spinal fluid, and then in the case of older children and adults to inject 30 cubic centimetres of the serum on three or four successive days and further quantities based on the findings from day to day. After the first or second injection the number of organisms is decidedly lessened, and from three to seven days after the first injection the fluid tends to become clearer and the polymorphonuclear cells are lessened and replaced by lymphocytes. The organisms also tend to become more intracellular from increased phagocytosis, and the leucocytosis which is present with the disease soon disappears. In about a week the fluid becomes clear and the organisms can no longer be cultured, although a few may still be found in the films.

Upon the general symptoms the effects of the serum are equally striking: the temperature falls, sometimes by crisis; there is a rapid improvement in the general condition, with disappearance of delirium, of headache, and of vomiting, but the head retraction and Kernig's sign may remain for a few days after the disappearance of the other symptoms. After using the serum in 33 cases I am convinced of its value both as a curative agent and as preventing those painful sequelæ which we have seen with such frequency in the past in those who have recovered from this disease.

THE OCCURRENCE OF A PECULIAR PROTEIN IN THE URINE.

BY JOHN HENDERSON, M.D., CH.B. GLASG.,
ASSISTANT PHYSICIAN, ROYAL INFIRMARY, GLASGOW.

THE following case is worthy of record on account of the occurrence in the urine of a protein which in its properties does not exactly coincide with any protein hitherto described. The case was admitted to the Glasgow Royal Infirmary, under the care of Dr. George S. Middleton, who first drew my attention to the peculiar urinary condition, and to whom I am indebted for permission to investigate the case. The patient was admitted on Oct. 13th, 1909, and the following is a summary of the report upon his condition in the ward journal:—

"J. M., aged 47, miner, admitted complaining of stomach disturbance, and loss of flesh and strength, of four months' duration.

Present illness began four months ago with pain of a jagging character in his right side, radiating from the right hypochondriac to the right iliac region. This was accompanied by fulness and tenderness over the gall-bladder. The patient became 'copper-coloured,' the motions were pale and offensive, and the urine was very high-coloured. He remained at work till ten weeks ago, when he was forced to take to bed for treatment, and during this period he has improved in several respects. The pain and tenderness over the gall-bladder have disappeared, and the jaundice has quite cleared up. He has lost flesh and strength greatly and is very weak. For the past eight weeks he has had very great thirst and frequency of micturition (he had often to rise four times during the night). He does not admit having had frequency prior to this. He has never been subject to headache, giddiness, backache, or swelling of the feet. One month ago he was seized with vomiting, which took place immediately after every meal. The vomit was sour and was not associated with pain in the stomach either before or after the act. He never vomited blood. He has since been on light diet, without any sickness or vomiting ensuing, though these return whenever any heavy food is taken.

Previous health.—At the age of 13 he had 'gastric fever.' Three years ago he suffered from hæmorrhoids, from which he lost a lot of blood, over a period of two months, since when they have not troubled him further. Otherwise he had always been strong and healthy till the onset of the present illness. There was no specific history.

Family history.—He is married, and has a family of five children. His social condition is fair. His food is good, but irregular, and he often has to carry his meals and to hurry through them. He is a teetotaler and a non-smoker.

Present condition.—He is thin and emaciated, and there is no subcutaneous fat. The muscles are soft and flabby and myoidema is markedly present. There is great atrophy of the scapular muscles. His skin is sallow, and there is a marked degree of general anæmia. The teeth are fair and the tongue is moist and furred. There is strabismus and leucoma in the right eye, with blindness, the result of an injury, and in the left eye iridectomy has been performed in consequence of injury. Temperature on admission was 98·4°, pulse was 72, and respirations were 20 per minute.

Abdomen: There is no distension, swelling, or peristalsis. The abdominal wall is lax. Epigastric pulsation is visible. There is no pain or tenderness on palpation and no evidence of abdominal tumour. Liver and spleen are not palpable. Percussion note is clear all over. The lower border of the stomach reaches almost to the level of the umbilicus. The limits of hepatic dulness measure 4 inches in midsternal, 5¼ inches in nipple, and 5½ inches in midaxillary lines. *Heart:* Apex impulse is in the fifth space, in the nipple line, and is visible and palpable. The transverse measurement of cardiac dulness is 3½ inches. The first sound is booming in character and is followed at the apex by a faint V.S. murmur, which is confined in its distribution. The second sound at the apex is reduplicated. At the aortic and pulmonic areas the sounds are normal. *Lungs:* Occasional moist crackles are heard at both bases posteriorly, otherwise there is nothing noteworthy. The sputa, on examination for tubercle bacilli, give negative result. Knee-jerks are active and there is no ankle clonus. Plantar reflex is extensor. Under examination the patient shows a good deal of nervous tremor.

Urine is pale amber in colour, acid in reaction, and has a specific gravity of 1015. There is no blood, bile, or sugar present. There is no albumen present, but on heating a copious white precipitate comes down, which at once dissolves on the addition of one drop of acetic acid. Microscopic examination of the sediment, which is scanty, reveals the presence of numerous tube casts and epithelial cells. The casts are epithelial, granular, and fatty.

Blood.—Red corpuscles, 2,210,000 per c.m.; white corpuscles, 6000 per c.m.; hæmoglobin, 30 per cent. Examination of a blood film shows a very definite diminution of the red cells, which do not stain well, and vary much both in size and shape. No nucleated red cells are seen. Blood pressure in the brachial artery is 102 mm. There is no undue tenderness on pressure over the long bones.

Note on Oct. 14th (Dr. M.).—*Urine:* On boiling, a copious precipitate, by no means phosphatic in character, comes down, which dissolves on adding one drop of acetic acid. This precipitate returns on the addition of liquor potassæ in sufficient quantity to render the urine alkaline. When the urine is floated on nitric acid a copious white precipitate is obtained, which forms a thick, solid, irregular mass when shaken up with the acid. No blood, bile, or sugar is present. Tube casts, as already mentioned, are found in large numbers in the deposit.

Note on Oct. 19th (Dr. M.).—Renewed examination fails to discover anything of consequence in the heart, lungs, or abdomen. There is some undue succussion, and the gastric tympanitic note extends somewhat unduly into the lateral region. There is no undue tenderness on percussion of the bones. The urine presents similar characters to the original specimen, though the precipitate on heating is not quite so freely soluble in acetic acid.

Note on Nov. 9th.—Since last note there has been a gradually increasing weakness. The patient does not sleep well and does not take much food. He has been sick occasionally. The vomited matter contained no free acid and showed no trace of blood. The urine has constantly presented the same characteristics, and tube casts have been regularly observed, though these are not now so numerous as formerly. The average daily output of urine since admission has been 70 ounces. Examination of the blood shows red corpuscles 2,100,000 per c.m., white corpuscles 5600 per c.m., and hæmoglobin 33 per cent. No nucleated red cells have yet been observed.

Note on Nov. 13th.—The patient has daily become weaker, and to-day, at his own request, he was taken to his own home."

Remarks.—The diagnosis in this case was doubtful. The striking features were the anæmia, cachexia, and wasting,

and the condition of the urine. Careful and repeated examination of the patient failed to detect any evidence of malignant disease, the presence of which was at first suspected. There was no evidence of disease of the bones. The blood presented the characters of a fairly severe secondary anæmia. The case was regarded as one of chronic nephritis of some standing, and probably of the "diffuse" variety, accompanied by a considerable degree of anæmia and a peculiar urinary condition.

The patient unfortunately chose to go home to the country, and it has therefore been impossible to have any further observation of his general condition. We have managed, however, to obtain at intervals specimens of his urine for examination. According to the latest report—Feb. 10th, 1910—his condition has not varied much since his return home, though at times he has been very weak. A specimen of urine obtained on this date presents the same characters as the original specimens.

Through the kindness of Professor D. Noël Paton and Dr. E. P. Cathcart I have been enabled to carry out a detailed examination of the properties of this unusual protein in the Physiological Laboratory, Glasgow University. Along with Dr. Cathcart I have prepared the following summary of the results obtained.

To the naked eye the urine presented nothing abnormal. Its colour was pale amber, its reaction distinctly acid, and it had a specific gravity of 1015. On subjecting it to the ordinary heat test for albumin an abundant white curdy precipitate was at once obtained. This precipitate was completely dissolved on the addition of one drop of 20 per cent. acetic acid. The precipitate had no resemblance to that of phosphates, which is frequently met with on performing this test. On contact with nitric acid in the cold a copious, thick, white precipitate was obtained, which disappeared on warming, to reappear on cooling. From these results it was evident that we had to deal with a protein other than ordinary albumin or globulin.

Professor Halliburton has remarked that "the coagulation temperature of a protein is a most untrustworthy guide to its identity." As a general rule the coagulation point of an albuminous urine may be placed somewhere about 70° C., and the coagulum thus obtained shows no tendency to disappear on raising the temperature to boiling point, and is insoluble in acetic acid. The protein present in this case coagulated at 56° C., and on further raising the temperature apparently tended partially to return to solution. As already noted, it was completely dissolved on the addition of one drop of acetic acid.

Further, an ordinary albuminous urine gives a precipitate on contact with nitric acid, which precipitate persists on short heating at 100° C. The present protein precipitated as usual in the cold with nitric acid, but disappeared on warming, to reappear on cooling.

With alcohol, ordinary protein is precipitated, and on heating this precipitate persists. In this case the precipitate occurred as usual in the cold, but disappeared on warming, to reappear on cooling.

All the ordinary protein tests were obtained—viz., marked biuret, Millon, marked Liebermann, and tryptophane reactions, and on boiling the urine with lead acetate in alkaline solution it blackened.

The protein was precipitated by all the ordinary reagents which precipitate proteins—viz., trichloracetic, tannic, and picric acids, &c. The protein was fully precipitated on half saturation with ammonium sulphate. After filtration this precipitate was dialysed against running water, and the product left in the sausage-paper behaved quite as in the original urine. The ammonium sulphate precipitate was further dialysed till free from salt, and it again showed the same properties. The material obtained from this salt-free product, either taken down to dryness in vacuo at a low temperature or precipitated with alcohol and dried, was found to be a whitish-grey powder, ash-free, and when in solution it possessed all the properties of the original body in the urine.

At various times unusual proteins have been described as occurring in the urine by Bence-Jones, Huppert, Ribbinck, Kühne, Noël Paton, and others, but though in some respects it offers points of resemblance, our protein does not correspond to any hitherto described.

With regard to the exact nature and source of this protein it is impossible to say anything meantime, but in a later paper we hope to discuss this question.

ROYAL SOCIETY OF MEDICINE.

CLINICAL SECTION.

Endothelioma of the Tongue.—Exhibition of Cases.

A MEETING of this section was held on April 8th, with Mr. A. PEARCE GOULD in the chair.

Mr. F. S. EVE read a paper entitled "Three Rare Tumours of the Base of the Tongue (Two of them Endotheliomata), with Remarks on the Surgery of Malignant Disease of the Tongue." In discussing the surgical aspects of the cases, he said that he considered that Syme's operation of severing the mandible was the best method of removing any growth involving the posterior half of the tongue, especially if it implicated the floor of the mouth. He did not consider that any growth of the floor of the mouth could be satisfactorily removed without dividing the mandible. The advantages of Syme's operation were that the lingual arteries were easily secured, the tissues of the floor of the mouth could be cleanly detached from the mandible, and the muscles attached to the tongue could be divided near their origin. The tongue should, as a rule, be removed before the glands. The disadvantages of Syme's procedure were that the wire used for uniting the jaw often gave rise to sinuses; also delayed union might occur and the fragments become loose. These disadvantages could be avoided by using a dental splint. Mr. Eve explained a method of removing glands from the neck, and thought that with certain exceptions only the glands on the affected side need be removed unless those on the opposite side were actually enlarged. The exceptions were, however, numerous, and included all growths originating in or approaching the middle line, those deeply infiltrating the under surface of the tongue, and those arising at the tip of the tongue or implicating the floor of the mouth at or near the frænum.

Dr. F. H. JACOB described a case of Acholuric Jaundice. Slight yellowness was noticed in the patient two years ago; there was weakness one year ago. Continuous slight jaundice with exacerbations, an enlarged spleen, great irregularity in the size of the red cells, and a number of nucleated red corpuscles were observed.—Dr. H. D. ROLLESTON suggested that a better name than acholuric jaundice was hæmolytic jaundice.

Dr. N. S. FINZI showed a case of Sarcoma of the Ear and Mastoid Region under radium treatment. The patient, a boy, aged 8 years, complained of earache in May, 1909, and was found to have a polypus. It proved to be sarcoma. A recurrence was treated by Coley's fluid in November last; there was temporary improvement, after which the growth made steady progress. When the boy came under Dr. Finzi's care on Feb. 15th, 1910, he had a large fungating bluish mass behind the ear about 1¼ inches in diameter. There were large fixed glands below the ear and under the sterno-mastoid, also small glands at the apex of the posterior triangle. Radium treatment was given, and in a week's time from the first application there was marked improvement, the growth and glands being smaller and much less tender, and that had since continued.

Dr. FINZI and Dr. WILLIAM HILL showed two cases. The first was a case of Malignant Growth in the Neck treated with Radium, with Recurrence in the Mediastinum. The patient was exhibited to demonstrate the possibility of treating large and deep malignant growths with radium; to show the necessity of thorough and radical treatment, which had not been sufficient in this case; and to show the ease with which a mediastinal growth could sometimes be seen in an instantaneous radiogram. The second case was one of Œsophageal Growth under treatment by radium. The growth was stated to be endothelial sarcoma. The improvement was demonstrated by means of radiograms. Dr. Hill demonstrated on this patient the method of inserting the radium apparatus into the gullet by means of his new form of œsophagoscope.

Mr. CHARTERS J. SYMONDS showed a case of Rodent Ulcer treated by radium by Dr. C. E. Iredell at Guy's Hospital. This patient was exhibited last December, and the radium had been, with a short interval, steadily applied. Improvement had progressed, and since the patient was last shown the induration on the outer side had almost entirely disappeared; particularly noticeable was the change in the lower

eyelid, which had become quite supple. The thickening connected with the lower part of the wound might, it was hoped, be attributed entirely to the cicatrisation.

In the discussion which followed Mr. C. R. C. LYSTER (Middlesex Hospital) said that during his experience with radium he had never seen deep-seated malignant growths influenced by radium. He agreed that superficial rodent ulcers could be easily and satisfactorily dealt with by radium.—Dr. W. S. LAZARUS-BARLOW (Middlesex Hospital) said that the cases shown were of the indeterminate type of cancer belonging to a group which he defied anyone to distinguish with dead certainty from inflammatory tissue. He knew from working in the laboratory that radium could cause acceleration as well as retardation of the development of cells. Clinical workers with radium would be very sorry for themselves if they ultimately found that instead of curing what they thought was cancer they produced what they knew to be cancer.—Mr. EVE described a case in which under the X rays an inoperable tumour of the neck disappeared.—Dr. HILL did not consider that radium would cure an advanced case of malignant disease of the œsophagus, but it would give relief.—Dr. FINZI believed that radium could influence a growth quite three inches from the surface.

Cases were also shown by Dr. F. PARKES WEBER and Dr. E. MICHELS, Dr. W. P. HERRINGHAM, Dr. A. F. HERTZ and Dr. F. S. ADAMS, and by Mr. GWYNNE WILLIAMS.

LARYNGOLOGICAL SECTION.

Exhibition of Cases and Specimens.

A MEETING of this section was held on April 1st, Dr. J. DUNDAS GRANT, the President, being in the chair.

Mr. HERBERT TILLEY showed: 1. A case of Healed Tuberculous Laryngitis treated by galvano-puncture. The patient, a woman aged 27 years, complained of hoarseness and was under sanatorium treatment for pulmonary tuberculosis. The left ventricular band was swollen, so that the corresponding vocal cord was invisible. Four deep punctures with the galvano-cautery had brought about the present satisfactory condition. 2. Intra-tracheal and Extra-tracheal (Tracheotomy Wound) Masses of Papillomata removed from a patient shown at the last meeting. 3. A Vulsellum-catch Forceps for firmly securing submerged tonsils in the operation for their more efficient removal. 4. A portion of Mutton-bone removed from the Right Bronchus of a woman, where it had been lodged for ten days. Her symptoms were constant irritating cough, numerous râles over the right base of the lung, and temperature 102° F. Removal under general anæsthesia.

Dr. G. C. CATHCART showed a girl, aged 12 years, in whom the Epiglottis was enormously Tumefied, completely Obscuring the Glottis, suggesting Tuberculosis. There were numerous enlarged glands in the neck. The patient had had diphtheria four years ago.—The PRESIDENT thought that it looked like tuberculosis of a mitigated type, and suggested application of the von Pirquet test.

Dr. L. H. PEGLER showed a case of Extreme Deflection of Triangular Cartilage, with Crest and Adhesions, and Anterior Prickle-shaped Spur, treated by Septal Fissure. Dr. Pegler's septotomes in different sizes were shown. The patient, a young man, aged 19 years, complained of recurring attacks of deafness, inability to breathe through the left side of the nose, constant "catching cold," and a disagreeable sniffing which annoyed both himself and his friends. Examination showed very marked deflection of the septum with ascending crest to the left, extending from a thorn-like spine in front to beyond the junction with the ethmoid plate posteriorly. The spur and anterior part of the crest were joined by adhesions to the inferior turbinal anteriorly, the atrophied condition of which still remains. A slight groove in the right side of the septum marks the angle of deflection. The right inferior turbinal was hypertrophied but breathing was carried on fairly comfortably on that side. Treatment consisted in sawing away the spur and crest under chloroform, followed by septal fissure on Moure's principle with Dr. Pegler's special forceps (septotome), and after right partial inferior turbinotomy inserting a thick indiarubber splint. The septum was forced over by the finger after the incisions had been made until the two cavities corresponded in capacity as they do now. The splint was worn quite comfortably for one week. The deafness, sniffing, and a troublesome watery discharge from the right and free nostril have ceased and the breath way is perfect.

The PRESIDENT showed: 1. A case of Malformation of the Soft Palate and Uvula in a girl aged 16 years. There was a perforation above and to the right side of the base of the uvula, but the nature of it was quite undecided. There was no such cicatricial tissue as would accompany a specific perforation and no history of such traumatism as could have accounted for it. 2. A case of Removal of Hypertrophied Anterior Lip of the Hiatus Semilunaris for long-standing muco-purulent catarrh in the ethmoidal cells and frontal sinus. Both middle turbinals were partially resected, but no relief from catarrh or headache was obtained until the operation on the outer wall was effected.

Dr. G. WILLIAM HILL showed a case of probable Sarcoma of the Right Tonsil in a woman, aged 48 years, of 12 months' duration.

MEDICAL SOCIETY OF LONDON.

Exhibition of Cases.

A MEETING of this society was held on April 11th, Dr. SAMUEL WEST being in the chair.

Dr. F. PARKES WEBER and Dr. G. DORNER showed a case of Chronic Muscular Atrophy (chiefly affecting the thigh muscles). The patient, a young man, aged 21 years, complained of muscular weakness in his legs, which prevented him from getting upstairs easily, and even made it an effort to cross his thighs when sitting down. He could not mount on to a chair as most persons could. There was likewise a certain deficiency of power in the movements of his shoulder-joints and upper extremities. On examination he appeared to be well developed except in regard to certain muscles. That the psoas and iliacus muscles were very much affected was shown by the patient's difficulty in flexing the thighs on the pelvis. The big muscles of the front and inner aspects of the thighs were weak and wasted and did not react to faradic stimulation. The wasting of the thigh muscles gave him something of a "Vogelbein" appearance of Hoffmann. The supraspinatus, infraspinatus, pectoralis major, and part of the deltoid muscles were likewise poorly developed, and the lower portions of the pectoralis major muscles did not react to faradism. The calf muscles were very large, and there was no obvious wasting in the muscles of the face, the muscles of the hands or of other parts not yet mentioned. The knee-jerks could hardly be obtained—that is to say, they were represented only by a slight muscular contraction. The plantar reflexes were normal. Fibrillary muscular twitchings could be sometimes observed in the muscles of the upper part of the trunk, the extremities, and the neck. The history was that at 10 years of age he was not able to run as well as ordinary children could. At 13 years there was some difficulty in getting upstairs and in mounting on a chair. The weakness in the legs had slowly increased, and since 15 years of age there had likewise been some loss of power in the upper extremities. In regard to other illnesses, it might be noted that he had gonorrhœa at 18 years of age, and he practised masturbation a good deal from 12 to 16 years of age. There was no history of any similar muscular atrophy in other members of the family. The disease appeared to be a form of very slowly progressing myopathy, chiefly affecting the thigh muscles, a type of myopathy to which Dr. Thomas Buzzard had specially drawn attention; it was analogous to Erb's juvenile type of myopathy in which the upper arm musculature chiefly suffered.

Dr. PARKES WEBER also showed a case of Osteopathy and Perforating Ulcer of the Foot in Syringomyelia and a case of Arteritis Obliterans of the Left Leg.

Mr. DOUGLAS DREW showed radiographs and lantern slides illustrating a case of Old-standing Dislocation of the Foot forwards, with fracture of the neck of the astragalus and displacement of the fibula on the tibia, which he had recently operated on. The injury resulted from violent flexion of the foot on the leg as the result of an accident while bobsleighing. It was found to be impossible to reduce the dislocation, which had been present more than a month, either by manipulation or by operative means until the astragalus had been removed. Mr. Drew commented on the rarity of the injuries and on their mode of production.

Mr. H. TYRRELL GRAY and Dr. L. G. PARSONS showed a Clinical Instrument for consecutive and simultaneous graphic records of the respirations, pulse, and blood pressure over a prolonged period of time. The apparatus was based on Dr.

Gibson's well-known instrument for obtaining a graphic record of the blood pressure. The following were its distinctive features: provision was made for a continuous tracing (50 feet of paper) over a period of about two hours; additional levers, connected with tambours for recording respiratory excursions, apex beat, and the pulse; and an adjustable lever marking a base line.

Dr. F. DE HAVILLAND HALL showed a case of Intrathoracic Aneurysm in a man, and Mr. CHARTERS J. SYMONDS showed a man upon whom he had operated for Abdominal Aortic Aneurysm by inserting bronze aluminium wire.

Mr. A. E. BARKER showed two patients, one a case of attempted Bone Grafting of the Tibia and the other a case of Rhino-scleroma.

Mr. W. H. BATTLE showed a case of Lipoma of the Left Palm and a patient with Neuropathic Disease of the Hip.

Dr. J. WALTER CARR showed a girl suffering from Fixation of the Joints (? Fibrous Myositis).

Dr. F. S. PALMER demonstrated a case of Total Ophthalmoplegia in a woman.

MANCHESTER MEDICAL SOCIETY.—A meeting of this society was held on April 6th, Mr. E. Stanmore Bishop, the President, being in the chair.—Dr. W. Milligan read a paper upon the Surgery of the Faucial Tonsils, with special reference to the operation of enucleation. The development and the anatomy of the faucial tonsils were first considered, special stress being laid upon the importance of recognising the supra-tonsillar fossa as a "dangerous zone." The faucial tonsils were then discussed as portals of infection, reference being made to the incidence of tuberculosis, rheumatic fever, &c. The operation of tonsillectomy was strongly recommended in preference to tonsillotomy and reasons were advanced for this preference. The various complications following operations upon the tonsils were then detailed, special mention being made of hæmorrhage and of the methods in use for dealing with it. Finally, the question of the administration of anæsthetics in operations upon the tonsils was considered and the advantages of operations under general anæsthesia were insisted upon.—Dr. G. E. Loveday gave an account of investigations he had recently made on the serum diagnosis of syphilis. The method employed was that advocated by Dr. Alexander Fleming, in which an alcoholic extract of heart muscle made up to 10 per cent. in normal saline was used as antigen, and sheep's corpuscles (normally hæmolysed by human serum) washed and made up to a 10 per cent. suspension in normal saline were used as an indicator. Using this method 44 out of 45 cases of clinical syphilis gave a positive reaction. On investigating controls, some cases which had almost certainly not had syphilis gave positive reactions. The extract was therefore reduced in strength and experimentally standardised to give a positive reaction only in syphilitic cases. The results with the standardised extract to date were: Out of 20 cases of clinical acquired syphilis 18 positive and 1 doubtful and 1 negative reactions were obtained. Out of 52 control cases 51 gave a negative and 1 a positive reaction; this case upon inquiry gave a history very suspicious of syphilis. The controls embraced, amongst others, cases of bacterial infection, gonococcal, tuberculous and pneumococcal cases, and cases of anæmia and chlorosis. The reaction was considered reliable.—Dr. G. H. Lancashire described a case of Chronic Crurogenital Eczema which developed suddenly while in hospital into an acute gangrenous condition, from which the patient died. The course of events pointed to an acute infective process, probably auto-infection.—Dr. Arthur Sellers, who made a pathological investigation of the organs after death, reported that on bacteriological examination the staphylococcus pyogenes aureus and bacillus pyocyaneus were found in enormous numbers in the gangrenous skin, in the kidneys, spleen, and liver, but not in the blood.

THE LATE DR. GEORGE CARPENTER.—In our obituary notice of the late Dr. George Carpenter the Queen's Hospital for Children was alluded to as being a separate institution from the "North-Eastern Hospital for Children," whereas there is but one hospital which was known as the "North-Eastern Hospital for Children" until 1908, when its name was changed with the sanction of Her Majesty Queen Alexandra and the King. Dr. Carpenter was appointed assistant physician to the hospital in 1903 and full physician in 1905.

Reviews and Notices of Books.

Accidental Injuries to Workmen with Reference to Workmens' Compensation Act, 1906. By H. NORMAN BARNETT, F.R.C.S. Edin. London: Rebman, Limited. Pp. 384. Price 7*s.* 6*d.* net.

IN this work Mr. Norman Barnett has had the advantage of the coöperation of Dr. Cecil E. Shaw, who has written an article on Injuries to the Organs of Special Sense, and of Mr. Thomas J. Campbell, M.A., LL.B., barrister-at-law, who has written the legal introduction. Since the introduction of the Workmen's Compensation Act of 1906 the need has been felt of a work which should deal comprehensively with the very difficult and vexed question of accidents and their results relative to the Act. The authors claim to have supplied this want and they are certainly to be congratulated on the success of their efforts. There is no doubt that everyone who is engaged in cases relating to the compensation of workmen will find the book of very great assistance, and there is a large amount of most useful information and advice which cannot fail to be of the greatest help to any medical man who is called upon to give evidence in cases of this kind. Also, the book will be of equal value to members of the legal profession, many of whom are frequently engaged in cases of this class.

The legal introduction is admirably written, and it brings out clearly the far-reaching changes which the new Act has made in the relation of employer and employee. It also continually emphasises the fact that these changes are for the benefit of those whose lot it is to toil and to earn their daily bread by the sweat of their brow. The term "accident" is not defined in the Act, and, as is stated, the question of accident is in very large degree a question of fact, so that naturally in any particular case different views are likely to be taken by the various parties concerned.

Numerous illustrations are given of typical legal cases in which difficulty arose in the decision as to whether the occurrence was an accident or not. The application of the Act to industrial diseases is fully considered. The various classes of persons coming under the definition of "workmen" are given, and also those to whom the term employer may apply. The considerations which are brought into play in determining the amount of compensation to be awarded as the result of an accident are fully discussed. Some excellent advice is given as regards the medical examination in compensation cases, and also as to the manner in which a medical man should give his evidence. It is satisfactory to learn that, in the opinion of the authors, medical men acquit themselves, with singularly few exceptions, in a manner creditable to their profession.

The question of compulsory operation in cases where workmen are claiming for injuries which might be benefited by surgery is fully discussed, and several very interesting cases are cited, going to show that if a workman refuses to undergo an operation which is likely to remove some of the effects of his injury then this refusal will be seriously taken into account in determining the amount of compensation due to him. A very important chapter deals with the making of medical reports and the giving of medical evidence. The advice given here is sound and helpful.

A brief account is given of the various injuries which may occur to the different bodily structures, but of necessity the space devoted to them is much too small for adequate treatment. It is obvious that special works in surgery must be consulted for information of this kind. The injuries to the organs of special sense are dealt with as fully as the limited space will allow, but here again it will be necessary for the medical witness to consult larger works in order to get the

necessary information which will be required in a particular case. In the appendix is given in full the Workmen's Compensation Act, and also a list of industrial diseases, and the report of the Departmental Committee on compensation for industrial diseases.

In conclusion, we again emphasise that the book is a valuable contribution to medical and legal literature; it should be possessed by everyone who is likely to be engaged in cases coming under the Workmen's Compensation Act.

The Human Species, considered from the Standpoints of Comparative Anatomy, Physiology, Pathology, and Bacteriology. By LUDWIG HOPF. Authorised English edition. With 216 illustrations and seven plates. London: Longmans, Green, and Co. 1909. Pp. 457. Price 10*s.* 6*d.* net.

THE science of anthropology is one which, from its very nature, should be of interest to members of the medical profession. Although as practitioners their attention is more particularly confined to the investigation of abnormal and diseased conditions, yet the study of man's place in nature, of his evolution and of his relations, both morphological and psychological, to the other members of the animal kingdom, is fraught with interest, and may be pursued with advantage. It is with such problems as these that Professor Hopf's interesting book deals. It contains within very moderate compass and presented in readable style a large amount of information, carefully marshalled and intelligently discussed.

The first part is devoted to a brief but interesting review of the surmises of primitive and savage tribes, and of the speculations of philosophers, ancient and modern, as to the origin of man, followed by a consideration of the distribution of mankind and of the various classifications of the human race. This part concludes with a general discussion of the discoveries made in regard to fossil apes, tertiary, quaternary, and neolithic man.

The second part, which is much larger than the first, is divided into three sections, dealing respectively with comparative anatomy and histology, comparative physiology and psychology, and comparative pathology and pathological anatomy. The aim the author had in view is, as he expresses it himself, "the comparison of the essential characteristics of man with those of the lower animals in the light of the results of recent research. Many a character hitherto regarded as distinctively human will be found to be shared by the lower animals, many another be proved man's indisputable possession, though here and there he may not be particularly edified thereby." In regard to the anatomy, histology, and physiology of human structures, as compared with those of animals, copious measurements and details are given and many illustrations, while any particular features or characteristics special to the human species are carefully indicated. Without doubt, however, the most interesting section of Professor Hopf's book is that dealing with the comparative psychology of man and animals. After briefly discussing the abode of the mind and the monistic and dualistic theories as to its nature, he proceeds to investigate the relation of the human to the brute mind. After referring to the dualistic or anthropocentric view of Descartes, and to the work of Darwin, he passes on to consider the view of Haeckel, supported by Klaatsch, that there is a psychic evolution up to man through the animal kingdom analogous to the progressive evolution of anatomical and physiological characters. The tendency of all modern investigations is to support strongly the view "that the psychical differences between man and animals are of degree only and not of kind." Professor Hopf, however, while admitting that animals act with deliberation, denies them the faculty of reason—i.e., the power of forming abstract as opposed to concrete judgments and associations of ideas. In this he parts company with Darwin and Haeckel; indeed, he goes further, and states that the faculty of reason seems entirely wanting in certain savages. Curiosity and the capacity to count are to be found in animals, as is also the power of measuring, but weighing is a faculty confined to man. Interesting accounts are given of the powers of speech and of the means of emotional expression in animals and their relation to those of man.

After briefly considering impulses and instincts Professor Hopf deals with social impulses and observances in man and animals in a few pages of striking interest. This section concludes with descriptions of modern discoveries in regard to the origin of religion, arts and handicrafts, painting, music, and writing in primitive man, and is illustrated with reproductions of various remains of the weapons and utensils employed, including the knotted cords of the South Sea Islanders, which served as genealogical registers and historical records. The last section is devoted to a review of comparative pathology and is necessarily brief, but it is suggestive and valuable, as indicating what a fruitful field this may be for further research. A brief appendix on comparative therapeutics contains some interesting observations on instances of mutual help and of the treatment of wounds in the animal kingdom.

We have read Professor Hopf's book with interest and can commend it as an instructive work on anthropology. We may also congratulate the translator upon the manner in which he has carried out his task; we cannot do this by name, as he modestly withholds his identity.

Gonorrhœa in Women. By PALMER FINDLEY, M.D., Professor of Gynæcology in the College of Medicine of the University of Nebraska, Omaha. St. Louis, Mo., U.S.A.: The C. V. Mosby Medical Book and Publishing Co. 1909. Pp. 112.

THE author has written this book for the purpose of awakening his readers to a greater appreciation of the supreme importance of the subject of gonorrhœa in women. In a short historical sketch he points out that the history of gonorrhœa is as old as the human race, and calls attention to the numerous references to the disease in the Bible. The large part played by this affection in the production of various inflammations of the female genital organs was first brought prominently before the notice of the profession by Noeggerath in 1878, but the full significance of the lesions caused and of their extent was first rendered certain by the discovery of the gonococcus by Neisser. From this time our knowledge of the occurrence of gonorrhœa in the female has been placed upon a sure foundation, since before the recognition of the gonococcus it was impossible to say with certainty whether a vaginal discharge was due to this disease or not. Undoubtedly Noeggerath exaggerated the facts. For instance, he affirmed that 80 per cent. of married men have had gonorrhœa, that 90 per cent. of these had never been properly cured, and that of every five married women three had acquired gonorrhœa. It is impossible to credit these statistics and they are undoubtedly exaggerated; but at the same time it must be admitted that the assertions of Noeggerath did a great deal of good, since they called attention to the fact that many women are in reality the victims of an uncured gleet in their husbands and that this condition is an important factor in the production of sterility in the female.

One of the great difficulties in the study of the gonococcus is that it can be grown outside the human body only very exceptionally. The author quotes Turro, who claims that he has grown it in acid media and successfully inoculated it into dogs, but, on the other hand, Bumm affirms that the

organism can only be successfully inoculated in the human body. It is a fortunate coincidence that the gonococcus soon loses its virulence when dried, otherwise epidemics of the disease would be not infrequent. While the frequent involvement of the glands of Bartholin is well recognised it is not so well known that the occurrence of suppuration in these structures is nearly always the result of a mixed infection with the staphylococcus, and the gonococcus has but little power of penetrating deeply into the tissue in this position.

The important part played by the gonococcus in the production of puerperal fever has only been fully realised of late years, and the author is therefore justified in insisting upon this with much emphasis. One of the most interesting sections is, indeed, that in which he discusses the question of gonorrhœal puerperal infection. Dr. Findley quotes from Taussig, who has given a good description of the clinical course of these cases, and who says that this form of puerperal infection is to be distinguished from streptococcic infection by its late onset, the moderate degree of fever, the absence of any signs of severe intoxication, and by the regular and proportionately slow pulse. The diagnosis must, however, rest upon the microscopical examination of the lochial discharge. Upon the whole the author is an upholder of the views of Noeggerath and is much impressed with the large number of cases of disease of the female genital organs which he believes have the gonococcus as their cause.

Dr. Findley has given a clear and interesting *résumé* of the subject, and if we do not altogether agree with his conclusions we must admit that he has many arguments on his side, and, as he points out, the more systematic bacteriological examination of cases of gonorrhœa in women would no doubt tend to prove his contentions. The book is an interesting one and thoroughly worthy of perusal.

Exercise in Education and Medicine. By R. TAIT MCKENZIE, B.A., M.D., Professor of Physical Education and Director of the Department, University of Pennsylvania. London and Philadelphia: W. B. Saunders Company. 1909. 8vo. Pp. 406. Price 15*s.* net.

THIS is an excellent book. Large as the subject is, the whole ground is covered and the author has dealt with its varied aspects equally well. It is so well written that, copious as the volume is, and full of technical details, it is interesting to read from end to end, while it would form an admirable compendium for reference both to those engaged in education and for general practitioners of medicine.

In the opening chapter it is difficult to accept the writer's definition of "second wind" as the "re-establishment of equilibrium between the production of waste and its elimination"; such a readjustment could not take place in so short a time. Second wind is a readjustment that occurs chiefly in untrained persons and is a cardiac phenomenon. The heart urged to a more rapid and powerful systole becomes distressed until it gets better accustomed to the rate of contraction required of it. The establishment of this condition is best seen in rowing, in which exercise the cardiac rate is determined by the respiration rate which is absolutely dependent on the rate of stroke. The account of the physiological output and "condition" of athletes describes a state which should not occur; and we doubt if it often does occur among athletes in England of any position in the athletic world, whether at schools or universities, or in any well-trained clubs. Professor McKenzie gives a most interesting account of the history of modern German and Swedish exercises illustrated with reproductions of numerous photographs; and such matters as jiu-jitsu and the Delsarte system and other kindred muscular methods are admirably and easily sketched.

There are full and sound chapters on exercise in education and the improvement of the physique of the very poor and the mentally defective. Some of the best parts of the book are those on exercise as applied to pathological conditions, notably those relating to flat-foot and scoliosis. The description of the mechanical problems of the feet is clear and well-written; and the exercises advised are closely studied and set forth in comprehensible terms. Other good matter are the sections on Oertel's treatment, on Schott's passive movements, and on the training of ataxia, based largely on von Leyden's methods. The illustrations of the Schott movements are photographed from life and are not as clear as the rougher line drawings such as those in Dr. W. Bezly Thorne's brochure. Well informed as Professor McKenzie is, he is careful to insist on the limitations of exercise and massage in medicine, and to avoid the common quackery of claiming that these methods can cure every mortal ill.

LIBRARY TABLE.

A Practical Guide to the Administration of Anæsthetics. By R. J. PROBYN-WILLIAMS, M.D. Durh. Second edition. London: Longmans, Green, and Co. 1909. Pp. 228, with illustrations. Price 4*s.* 6*d.* net.—That this little book should have entered a second edition is sufficient proof of its merits as a manual of instruction to the student. The new edition contains short accounts of the use of ethyl chloride and of spinal analgesia which were not previously included. In some other respects, however, the author has not taken full advantage of the advances that have been made in anæsthetics since the production of his first edition. He does not give a sufficient account of the use of ether by the open method, nor any at all of the application of this for nasal inhalation in long operations for removal of the tongue, &c.,[1] and he might with advantage have devoted a little more space to the treatment of the important condition known as "delayed chloroform poisoning," in connexion with which so much has been written on which he could have drawn. Furthermore, much has been learned in connexion with the treatment of shock of which the author has not, we think, sufficiently availed himself. It is, however, ungracious to cavil at sins of omission in an intentionally compressed book, and we prefer to point out the general excellence of the arrangement of the material, the great superiority of several of the illustrations over those usually found in a work of this character, and the admirable clearness of description where complicated apparatus is concerned. We should like, by-the-bye, to have seen some description of one, at least, of the "plenum system" of chloroform-regulating inhalers and a consideration of the advisability of this method.

Text-book of Nervous Diseases and Psychiatry. By CHARLES DANA, M.D., LL.D., &c. Seventh edition. London: J. & A. Churchill. 1909. Pp. 782. Price 25*s.* net.—This is the seventh edition of Professor Dana's text-book. So far as the neurological section is concerned revision has brought its material up to date, while much has been added in the descriptions both of organic and functional disease. The author has made material additions to the sections on histology and on the anatomy and physiology of the brain. It is perhaps unavoidable that in a book intended for students and practitioners a rather more dogmatic tone than the actual state of our knowledge warrants should be adopted, while much that has tentatively been adduced by investigators is clothed in words which suggest that the points in question are *choses jugées*. The section on psychiatry is meagre, and neither the classification adopted nor the descriptions of the various syndromes are really up to date. The style of the work is not unexceptionable. In several instances, though we have thought that

[1] THE LANCET, May 7th, 1909.

we have caught the meaning of the author, we have had to remain in doubt, since the purport of the words, as we have assumed it, has not been their face meaning. Spelling also is not infrequently at fault. The illustrations have been well selected.

Obstetrics for Nurses. By JOSEPH B. DE LEE, A.M., M.D., Professor of Obstetrics, Northwestern University Medical School. Third edition, thoroughly revised and enlarged. London and Philadelphia: W. B. Saunders Company. 1909. Pp. 512. Price 12*s.* net.—In reviewing the first edition of this book we indicated that it was likely to be of great assistance to nurses and that we could recommend it. The fact that the present is the third edition shows that it has met with the success it deserved, and we have no doubt that other editions will in due course be called for. Very little change has been found necessary in this edition. A special feature of the work is the illustrations, which are exceedingly good and should be very helpful to nurses in elucidating the text. The section on premature infant feeding is one of the best in the work, and we have read with much interest the description of what Dr. De Lee calls the "incubator station" of the Chicago Lying-in Hospital. The arrangements appear to be most complete, and even include an incubator ambulance for the transport of these premature children to the hospital. This is a perfect incubator in miniature, with a circulating hot-water system heated from the outside by an alcohol lamp, well ventilated, and lighted by electricity. It can be readily carried by one person, and the child in transit can be observed through a window in the top. The glossary has been made more useful by inserting page references to the text, so that a nurse after obtaining a definition of a word may refer to the text for a full description of the subject. There is a good illustration of Bier's congestion method of treatment for mastitis. We have no doubt that nurses who read and profit by this book will, as the author hopes in his introduction, become in reality missionaries spreading the gospel of good obstetrics.

International Sport. By THEODORE ANDREA COOK. London: Constable and Co. 1910. Pp. 255 + 181. Price 3*s.* 6*d.*—The subtitle on the title-page not only reminds us of the days of Queen Anne but forms an excellent digest of the scope of the volume: "A Short History of the Olympic Movement from 1896 to the Present Day, containing the Account of a Visit to Athens in 1906 and of the Olympic Games of 1908 in London, together with the Code of Rules for Twenty Different Forms of Sport and Numerous Illustrations." There is no doubt that the rules adopted at the Olympic Games will exert a wide influence in the near future on all athletic competitions, even in the smallest villages, and gentlemen who are asked to act as judges and officials in rural sports who have, perhaps, not gained any systematic experience will find this volume valuable. Apart from that value the volume is interesting as a record of important athletics and as a sketch of the modern antiquarian view of Athens and the Illyrian coast. The author is one of the highest authorities on athletics, a well-known oar, a swordsman of the first class, and the editor of the leading journal of sports in the world, while his works descriptive of mediæval France are valued alike for charm of writing and accuracy of detail. The same charm and accuracy of archæology present themselves in the account given here of Athens, Spalato, and Ithaca. The question of the value of international contests in sport is a difficult one: the view that they cause too much friction and ill-feeling is not without a good deal of support. But it is probable that the disputes over athletic events are accentuated in the press for journalistic purposes, while an enormous quiet *camaraderie* of feeling is established between the competitors and their supporters. There are about 1000 competitors in these big international meetings, and if a dozen of them emerge with grievances against the judges the balance of good feeling is on the right side.

JOURNALS AND MAGAZINES.

Archives of Internal Medicine. Vol. V., No. 2. Feb. 15th, 1910. Chicago: American Medical Association. Price $4 per annum of two volumes. Single copies, 50 cents.—The contents of this number are: 1. The Effect of Digitalis on the Ventricular Rate in Man, by Dr. A. W. Hewlett of Ann Arbor and Dr. J. T. Barringer of New York. Two cases are recorded and tracings are given illustrating the effect of digitalis upon the ventricular rhythm. 2. Emphysematous Gangrene due to a Member of the Colon Group, by Dr. Robert Goldsborough Owen of Iowa City. He finds that emphysematous gangrene may be due to anaerobic or to aerobic organisms, the most common agent being the bacillus aerogenes capsulatus, otherwise known as bacterium Welchii. An organism described by Lanier, which Welch regards as an aerobic variety of his gas bacillus, together with organisms described by San Felice, Corner and Singer, and Klein, should, according to Dr. Owen, all be regarded as varieties of the bacillus coli. 3. An Experimental Study of the Antitryptic Activity of Human Serum, by Dr. Richard Weil of New York. A satisfactory explanation of this phenomenon is regarded as impossible until further work clears up some of its details. 4. Some Cases of Low Temperature, by J. F. Munson of Sonyea, New York. Some interesting cases in which a considerable degree of hypothermia was observed in an asylum are recorded. It was found to occur in patients of low mental grade suffering from some acute or chronic infection, and in most instances it was agonal or pre-agonal. 5. The Problems of Experimental Nephritis, by Dr. Richard M. Pearce of New York. This important paper contains an interesting review of recent work on the subject and has an extensive bibliography appended to it. 6. A Study of the Presphygmic Period of the Heart, by Dr. G. Canby Robinson and Dr. George Draper of Philadelphia. The authors find that the presphygmic period, which is the time that elapses between the commencement of ventricular systole and the opening of the aortic valves, is from 0·07 to 0·085 second normally, and that its duration may vary markedly under various pathological conditions. Details of these variations, illustrated by tracings, are given, and the authors hope by further work to establish their prognostic value.

The Burlington Magazine.—We have received the April number of this sumptuous monthly magazine, the contents of which make, as usual, an intimate appeal to all interested in different phases of art and artistic production. There are many medical men who are virtuosi, and a collection of the paintings, prints, etchings, china, and silver in possession of the medical profession would form a very noteworthy exhibition. Those of our readers who are in this class hardly need to have the merits of the *Burlington Magazine* brought before them. But apart from avowed collectors who take a special interest in particular phases of art, there is a large class of medical men, and we know that it is growing, who admire and enjoy works of art without either making a collection or aspiring to the position of the expert. To these the article by Mr. Claude Phillips on the Italian pictures of the Salting collection will be of great use. It happens that this group of pictures is not, as Mr. Phillips allows, one whose importance is obvious on a superficial survey, and his straightforward comments upon it are likely to be useful to many members who hardly recognise the debt owing to the deceased benefactor of the National Gallery.

THE LANCET.

LONDON: SATURDAY, APRIL 16, 1910.

The Debate on the Prevention of Destitution Bill.

ON the afternoon of Friday, April 8th, Sir ROBERT PRICE moved in the House of Commons the second reading of a Bill drafted with a view to carrying into effect the reform of the Poor-law upon the lines laid down in the Minority Report. It can hardly have been expected by anyone in the House that the debate which followed would be closed by the fulfilment of its avowed object, and in the end the discussion of the Bill stood adjourned soon after 5 o'clock with little prospect of immediate renewal. Nevertheless, it cannot be said that nothing was achieved. The laying before the House of Commons of a concrete proposal for Poor-law reform, contained in a Bill consisting of 95 clauses, and with references to 80 existing Acts of Parliament, will enable many to realise more clearly than they have already done that the "breaking up of the Poor-law," a phrase with which they have become very familiar during the past few months, is not a legislative step which can be taken with a light heart and an easy mind in the course of a session's ordinary work. Our readers, at any rate, will find a great deal that is both instructive and interesting in the speeches which resulted in the measure in question being talked out in the House in the course of an afternoon. There can have been no expectation that fundamental differences of opinion coincident with party lines would be expressed by the Prime Minister and the Leader of the Opposition, but all were anxious to learn, if possible, what Mr. ASQUITH and Mr. BALFOUR might think about the reports of the Royal Commission, for the appointment of which the latter was responsible. The result was not disappointing, except perhaps to those who pictured to themselves at least a forecasting of the speedy "breaking up of the Poor-law" and a unanimous condemnation of the much-abused boards of guardians. The Premier, the Leader of the Opposition, and the President of the Board of Trade all spoke, and the essential quality of their speeches was that of moderation. They deprecated the setting up of the one report against the other, and the advocacy of the views of the Majority or of the Minority expressed in catch words and phrases, or, as Mr. BALFOUR expressed it, in "labels." They were careful to point out how much the two documents have in common, but at the same time they refrained from any suggestion that proposals for legislation founded on opinions expressed in both would necessarily meet with their approval. They were in accord as to the importance of the subject, which, as they pointed out, was far beyond the possibility even of superficial treatment in the course of a single afternoon at the invitation of a private member, and they treated the matter in accordance with a phrase of Mr. BALFOUR, who said early in his speech: "All you can say is that a debate of this kind has great uses in giving honourable Members an opportunity of expressing their various points of view, in bringing the whole subject before the country, and in giving the Government an opportunity, I will not say to pronounce on this great question, but to put some of the most important considerations which should be borne in mind before the House and before the great and increasing body of public opinion outside this House which takes an interest in this vital social question." The services done in the administration of the existing Poor-law by the boards of guardians, and the progress achieved in recent years by the Local Government Board as the central authority came in for commendation on all sides.

Mr. JOHN BURNS made some especially significant observations upon the improved treatment of the poor and upon the results accruing from it under the existing system, for which he claimed credit not for the guardians only, or for his department, but for the community as a whole. He also acknowledged that he had taken during the last few months what was "good, sane, and practical" in both the Majority and Minority Reports and had tried to apply it to the great problem with which he had to deal. Mr. BURNS also, like several of those who preceded him, including Mr. BALFOUR and Mr. ASQUITH, referred to the serious question of the increased, and not ascertained, expenditure necessarily involved in the Bill before the House, and in any drastic change in Poor-law administration. Altogether the outcome of the debate was the recommendation of caution and of the improvement of detail introduced with the aid of existing machinery. There was no eagerness shown for the "scrapping" of the old machinery without waiting to estimate the price and efficiency of that proposed to replace it. Additional interest is lent to this possibly unexpected feature in the debate by the recent publication of a proposal in outline for the utilisation and adaptation of existing Poor-law areas and boards of guardians, the author of which is Mr. CHARLES BOOTH. Mr. BOOTH, it will be remembered, retired from the Royal Commission before its proceedings were concluded, but was specially thanked by his colleagues in their report for a most valuable body of statistics which, at his own expense, he compiled for their information. An interesting feature in his present suggestion lies in the fact that he expresses himself in accord with Dr. ARTHUR DOWNES who, although he signed the Majority Report, stated his mistrust of the drastic changes of administration proposed by it in a memorandum which followed it. In that document he questioned the wisdom of the abolition of directly elected *ad hoc* authorities and the substitution for them of bodies largely independent upon public election; and he also suggested that the areas proposed for the new Public Assistance Authorities would be in many instances insufficient to enable them to carry into effect the classification of the objects of their care. Dr. DOWNES, in that memorandum, expressed himself as indebted to Mr. BOOTH for many of the figures upon which he founded his opinions. And Mr. BOOTH, in his introductory observations, refers to his own opinions as being shared by Dr. DOWNES. Mr. BOOTH'S scheme has for its motive the retention of directly elected

authorities for the relief of destitution operating in areas sufficiently large to permit of classification of separate institutions. In order to obtain this he would retain the present parish areas as the units of each union, and group the existing unions under district Poor-law boards. In these boards he would distinguish between urban and other groups of unions, for in the former case he would recommend the use of existing union areas as electoral districts for the board, and in the latter would have each union in the group represented on the board by its chairman or vice-chairman, and possibly by one other member. To these popularly elected members in both cases (urban and non-urban) he would add nominees of the Local Government Board in numbers proportionate to the Exchequer grant enjoyed by the district.

We have here a proposal consistent with the utilisation of existing machinery and involving no very great departure from established methods, but at the same time providing facilities for improved administration controlled by directly elected representatives of the ratepayers. It has against it two formidable competitors in the schemes propounded in the Majority and Minority Reports, but there is no evidence of the leaders of any party in Parliament having any marked desire to put forward and support either of these or even a combination of the two. On the question, however, of the direct election of guardians of the poor as a separate authority we may refer our readers to the adverse opinions to be found in the Majority Report (Part IV., Chapter II.) based upon the small amount of interest shown by the electorate and upon the difficulty of obtaining as candidates the best men and women available. In the circumstances, when we consider the vastness of the interests and the complexity of the questions involved, we should regard it as satisfactory that there is no likelihood of drastic changes being initiated hastily and without due consideration. On the other hand, if we have not seen any scheme propounded as yet which approximates very closely to the new and reformed system which we may expect future generations to enjoy, we may yet anticipate the extension of the work of the existing boards of guardians and of other agencies in various directions with beneficial results, credit for which will be due to the Majority and Minority Reports of the Poor-law Commission. There is no need of drastic legislative change, for example, in order to secure desirable reform in many matters relating to the care of the sick. The just claims of the Poor-law Medical Service demand attention and need not wait for the constitution of new Poor-law authorities before they are considered. Moreover, these claims are not the selfish demands of individuals for emoluments and personal advantages, but are based upon the desire of a body of public officials of great and increasing importance to see their good work in the past recognised and its efficiency in the future, according to modern ideals, ensured. We would point out that the improved treatment of the sick poor inside and outside the wards of Poor-law institutions has not been inspired by boards of guardians or by the force of public opinion, although the latter has, no doubt, supported the medical profession. It has been the outcome of the zeal of those who have been engaged in the Poor-law Medical Service and of the progress of medical science.

The Localisation of Cerebral Function: the Goulstonian Lectures.

RECENT years have seen very considerable advances in our knowledge of cerebral function and its exact localisation, and the thought of the days when the phrenologist placed philoprogenitiveness in the cerebellum and associated linguistic talent with prominence of the eyeballs only provokes a smile. Yet the impression left by a perusal of the elaborate and painstaking researches embodied in the Goulstonian lectures of Dr. J. SHAW BOLTON of the Lancaster County Asylum, lectures which represent 14 years of patient labour, is not so much one of wonder at what has been accomplished as almost of dismay at what remains to be performed. Dr. BOLTON'S modesty leads him to describe his work as unsatisfactory and incomplete, but these lectures, as a contribution to the study of cerebral function, will assuredly be of permanent value, and form a notable addition to the productions of English neurology.

The work, commenced as long ago as 1878 by BEVAN LEWIS and HENRY CLARKE, of differentiating the cerebral cortex on histological grounds, has been very distinctly advanced by A. W. CAMPBELL and by BRODMANN, and now no text-book of neurology is complete without a map of the cortex in which areas which differ in histological characters are clearly marked off from each other. It is true that unanimity in this task of delineation has not been reached, although the main features of the cortical map have been established. This is partly to be attributed to personal differences of opinion in the matter of subdivision, and partly to differing methods of describing the cell lamination of the cortex. Dr. BOLTON has taken as the basis of his work the division of the cortex into five primary laminæ, as follows: (1) the outer fibre lamina or superficial layer; (2) the outer cell lamina or pyramidal layer; (3) the middle cell lamina or granule layer; (4) the inner fibre lamina, which in certain regions contains such bodies as the Betz cells and the solitary cells of Meynert; and (5) the inner cell lamina or polymorphic layer. To take a single illustration of how these layers differ relatively in various parts of the surface of the hemispheres, the third layer is almost wanting in the cortex of the ascending frontal, pre-Rolandic, or precentral convolution, whereas in the occipital region it is of great depth and is even duplicated. Such a distinction inevitably leads to the suggestion that it may correspond to difference of function, and this, baldly stated, is the problem with which the investigator is faced. Only those who have a first-hand acquaintance with cerebral histology can form any true idea of the immensity of the task. Before it can be entered on at all it is essential to have a uniform method of measuring the layers of the cortex, and it is necessary to define the exact regions of the cortex which are capable of measurement. Dr. BOLTON takes micrometric measurements of the cortex of any given area in four places—viz., on the flat surfaces of convolutions, at the apices or fissure lips, at the bottoms of fissures, and on

the sides of fissures. Measurements taken at these four spots he unites to obtain an average, and only then does he consider himself in a position to compare the cortex of one part of the brain with that of another, or of one case with that of another. The question of individual differences obtrudes itself ere any satisfactory comparison can be made, and Dr. BOLTON is convinced that both in projection areas of stable organisation (such as the so-called motor area) and still more in specialised regions of association (for example, the prefrontal area) such differences may be very considerable. The next step is to determine by these micrometric methods the manner in which the lamination of the cortex is evolved. If the prefrontal cortex be chosen by way of example, it can be definitely determined that evolution proceeds from within outwards, and that the inner cell lamina approaches the adult depth at birth, at which date the middle cell lamina is about three-fourths and the outer cell lamina still little more than one-half of the adult normal depth. Further, it can be demonstrated with certainty that the evolution of the cortical laminæ is earlier in the occipital (visuo-sensory) area than in the parieto-occipital (visuo-psychic or association) area, and earlier in the latter than in the prefrontal or higher association zone.

Yet all this new and important anatomical and embryological investigation is but a preliminary to the development of Dr. BOLTON'S main thesis, which is, that the essential physical basis of mental disease consists on the one hand in a true subevolution, or defect of development, of the cell laminæ of the cortex, and on the other in degrees of decrease of the cell laminæ, which is of the nature of a true involution or dissolution. It is impossible to do more than merely indicate some general conclusions, based on the average measurements of 30 cases of mental disease, grouped under visuo-sensory, visuo-psychic, and prefrontal regions. Dr. BOLTON finds that a definite relationship exists between the depth of the prefrontal cortex of the respective cases and the degree of amentia or dementia which existed. No such relationship obtains in the case of the other two regions measured. Further, if we consider the individual cell laminæ, we find that Dr. BOLTON is led to the conclusion that the inner cell lamina is the fundamental cell layer of the cortex, and is concerned with the performance of the instinctive activities: it is below the normal depth in the prefrontal cortex of imbeciles and dements unable to attend to the calls of nature or to feed themselves; while the second or pyramidal layer is concerned with the psychic or associational, in contradistinction to the instinctive, activities of the cortex. In a case of well-marked dementia in a formerly intelligent adult, from the point of view of total depth the visuo-sensory cortex was normal, the visuo-psychic was reduced 6 per cent., and the prefrontal 13 per cent. From the point of view of individual laminæ the second or pyramidal layer was reduced 6 per cent. in the visuo-sensory area, 13 per cent. in the visuo-psychic area, and no less than 24 per cent. in the prefrontal area. Evidence is adduced from an examination of the cortex of other mammals to support the view of the function of the cortical layers mentioned above. In the precentral area the combined depth of the lower laminæ is practically the same in the rhesus as in man, and is one-fourth greater in the dog. On the other hand, there is a vast difference in the three cortices with regard to the evolution both in depth and in content of the outer cell or pyramidal lamina, which attains its maximum in man. The conclusion is that in organic and instinctive activities there is little between man, the monkey, and the dog, whereas the psychic, associative and educative functions of the former are paramount.

It will be seen that Dr. BOLTON approaches the problem of the correlation of structure and function from a novel standpoint, and has advanced a hypothesis of the function of the cortical laminæ which receives material support on both clinical and pathological grounds. It throws light on the vexed question of the physiology of the central convolutions and on many other matters of dispute, such as the relation of the intermediate precentral cortex to the precentral cortex. We are not able to follow Dr. BOLTON in all his contentions, and we may disagree with his interpretations of some of his facts. But this is not the time for minute criticism. However incomplete the lecturer may feel that his work is, he is to be congratulated on a most stimulating and suggestive contribution to the study of the localisation of cerebral function, conceived in a scientific spirit and carried out with consummate patience.

Deaths under Anæsthetics.

WE publish in another column the report of the inquiry into the question of deaths resulting from the administration of anæsthetics which has been made by the Coroners' Committee, to which Departmental Committee of the Home Office the matter was referred as an additional reference.[1] Most of our readers will probably agree with our view that the recommendations, which we are glad to say were unanimously adopted, are sound. They will undoubtedly help to protect the public in many directions. Some will feel that the report does not go quite far enough, and the difficult question of local anæsthetics has been treated with timidity; but as a whole it endorses substantially the views of the General Medical Council, and these were generally received by the medical profession as well-considered and wise. The General Medical Council, it may be remembered, adopted among others the following findings of its Anæsthetics Committee:—

> That it is desirable in the public interest that the administration of anæsthetics for the purpose of inducing unconsciousness or insensibility to pain during medical, surgical, obstetrical, and dental operations or procedures should be restricted by law to duly qualified medical practitioners, due provision being made for the practical instruction of students, and for cases of emergency.

And—

> That it is expedient in the public interest to provide that the person who administers the anæsthetic for the purpose of inducing unconsciousness during any medical, surgical, or dental operation or procedure should not be the person who performs the said operation or procedure, due provision being made for the cases of emergency.

It seems to us that in the first of these findings the Departmental Committee might have found complete justification if it had decided to limit the use of local anæsthetics to registered medical and dental practitioners. Upon the point where the greatest discussion has so far arisen—viz., the

[1] The main report was reviewed in THE LANCET of April 9th, p. 1909.

position of the dentists with regard to the administration of certain specified anæsthetics—the General Medical Council approved the conclusion that having regard to existing conditions it is desirable in the public interest that duly qualified dental practitioners should be authorised to administer certain specified anæsthetics, such as nitrous oxide gas, for the purpose of inducing unconsciousness or insensibility to pain during dental operations or procedures. The Departmental Committee takes the same view.

So that in the main principles laid down by the General Medical Council the report of the Departmental Committee concurs, while we are glad to see that the Committee definitely recommends that legislation should follow upon their report:—

> As the law stands at present [they say] the administration of anæsthetics is under no regulation. Although a man cannot sell a glass of beer to another without a licence, he may drug that other person to his heart's content, without let or hindrance from the law. Apart from any criminal intent, a bone-setter, or a beauty-doctor, or a quack of any kind is as much at liberty to administer an anæsthetic to his patient for the purpose of an operation as a qualified medical anæsthetist. If an accident happens as a result of the administration, the fact that the person administering the anæsthetic was not qualified might, of course, be material as bearing on the question of negligence, civil or criminal. We think that this unregulated state of affairs constitutes a serious menace to the public, and that the administration of anæsthetics should be carefully regulated by law. We proceed now to consider the different classes of anæsthetics, and the regulations which in our opinion should be applied to them.

This expression of opinion, with which all medical men will be in agreement, brings the recommendations of the Departmental Committee practically into line with those of the General Medical Council, for, like the Council, it is strictly opposed to single-handed anæsthetising and operating except in cases of urgency. In connexion with the employment of nitrous oxide gas, the Committee expresses a strong opinion that the same person should not administer the gas and perform the operation, while they realise that this principle applies with increased force to such anæsthetics as chloroform or ether.

The last recommendation made by the Committee we would single out for special notice. It is an excellent idea that a small standing scientific committee should be appointed by the Home Office to deal with the subject of anæsthetics, their composition, their methods of administration, and the relative measures of security which can be obtained by such methods. That the administration of anæsthetics is not yet an exact science is proved by the conflict of medical opinion which is only too ready to arise when a question concerning anæsthetics is under debate, and the labours of a standing committee might clear up some of the disputed points. Again, the dangers arising from the improper administration of anæsthetics, if they have been exaggerated in some quarters, are very real—this is proved by the list of the fatalities, progressively increasing in number, supplied to the Committee by Dr. F. W. HEWITT. The Committee rightly refused to make absolute deductions from figures connected with widely varying circumstances, but it acquiesced in the important conclusion that a certain proportion of an increasing number of deaths under anæsthetics must be regarded as due to preventable causes. It would be the duty of a Standing Committee to inquire into all such fatalities and to arrange the information in such form that a proper statistical return could be made from which deductions of the most absolute kind could be drawn. We hope that legislation will quickly follow upon the lines indicated in the report.

Annotations.

"Ne quid nimis."

RAG-FLOCK.

WE have appealed again and again for an official system of control over the manufacture of rag-flock, which, as we have proved in a practical investigation, may be derived from the filthiest possible sources. The matter has now received the serious consideration of the Local Government Board, and the report just made to the Board by Dr. Reginald Farrar, which is supplemented by reports from Mr. Cecil Warburton, Professor G. H. F. Nuttall, Dr. G. S. Graham-Smith, and Dr. F. C. Garrett, amply justifies the terrible conclusions arrived at by THE LANCET Commissioners in 1907, 1908, and 1909. In an introductory note to the reports Dr. Newsholme says definitely that it is evident from Dr. Farrar's report that the existing conditions under which rag-flock is produced are far from satisfactory. The rags employed are of the lowest and cheapest grade. They consist generally of cast-off clothing and strips of old carpet which may have been picked out from refuse heaps, and although in the tearing machine much of the dirt is removed from the materials from which the flock is manufactured, a large quantity of dirt remains. Dr. Farrar estimates that from 70 to 90 per cent. of the flock used for bedding and upholstery is neither washed nor sterilised, and he finds it difficult to exaggerate in describing the filthy nature of the material. We quote one paragraph upon this point. "Old trousers," he writes, "often badly stained with urine and fæces, are among the commonest of the articles which I have seen pass unwashed into the tearing machine in many flock factories, and some of the other garments used are almost equally filthy." "Some manufacturers," he adds, "purchase old beds and work up the contained flock unwashed with freshly torn material," and "several foremen and workpeople who have been many years in the trade have assured me that they have not infrequently seen surgical bandages and dressings, and even sometimes stained 'towels' torn up unwashed for flock." Mr. Warburton reports that lice and (*a fortiori*) their eggs may pass through the flock-making machine without being crushed. Although the lice without food would probably not survive in the bedding made from verminous flock, yet the eggs may take a month or more to hatch, and "it is quite possible that living eggs might be present in bedding." Professor Nuttall and Dr. Graham-Smith record a number of bacteriological and pathological experiments, and cases are quoted of septicæmia set up in mice by inoculating them subcutaneously with untreated flock shoddy. They conclude, however, that it is impracticable to set up a bacteriological standard of the purity of flock. Dr. Garrett finds that there is no difficulty in discriminating between clean and dirty flocks by chemical analysis, the differences in regard to the figures for chlorine being very wide. On the question of a standard of purity Dr. Farrar suggests that if in the public interest a standard of cleanliness for rag-flock is prescribed, such a standard should be selected as can be, and is by

several manufacturers, attained with the employment of methods now in use, the application of which will not cause undue disturbance of trade. The standard should neither be so high as to be unduly difficult of attainment by the use of existing methods, nor so low as to encourage manufacturers to mix unwashed with washed flock while keeping within permissible limits. Dr. Farrar suggests that it would be reasonable to fix 10 milligrammes of chlorine in one litre of wash prepared on regulated lines, or 30 parts per 100,000 of flock, as the permissible limit of impurity. These interesting reports bring to light facts which can leave no doubt at all in the minds of all public health administrators that the sale of unwashed flock should be prohibited, and it is the immediate duty of the Local Government Board, we consider, to issue regulations which shall provide for the suppression of an offensive trade and a most insanitary state of affairs. Several manufacturers, notably Mr. T. R. Freeman of Monkton Coombe Mills, much to their credit and common sense, have begged for a long time for legislative control which would make this business clean. Until this is done flock produced on wholesome hygienic lines is handicapped because nasty offensive rags can be sold unwashed and unclean for the same purpose, but at an obviously cheaper rate.

DR. JOHN RUTTER AND THE LIVERPOOL MEDICAL INSTITUTION.

WE have received from Mr. T. H. Bickerton two pamphlets relative to the history of the Liverpool Medical Institution, the one being a historical sketch of Dr. John Rutter, the founder of the building, and the other an account of the various vicissitudes which the institution as an association has passed through up to the present time. The institution, as an association, was an amalgamation of the Medical Library, the Medical Institution, and the Medical Society, and after 1848 the Pathological Society also joined. For the building, which was inaugurated in 1835 and opened in 1837, the institution was fortunate in receiving a donation of £1000 and the site for a nominal rent from the corporation. The society continued to hold its land at the nominal rent, the lease having been granted by the corporation for 75 years from 1840, until in 1881 they applied for a renewal of the lease. The Lords of the Treasury, who had to be applied to by the corporation, decided that they could not give their consent to the application for renewal, which the corporation were quite ready to grant, the reason, if it be a reason, given being that the lease did not run out till 1915. In 1902 the trustees of the institution waited on the estates committee and were informed that the lease would not be renewed unless a fine of £817 4*s.* were paid. However, owing to the prompt action of the authorities of the institution, a history of the institution was printed and circulated drawing attention to the former action of the corporation in granting and being willing to renew the lease, and in 1904 the estates committee recommended that the trustees of the institution should be offered another lease of 75 years on payment of a nominal fine of 10 guineas. In this happy manner ended a most critical episode in the history of the institution. Of Dr. John Rutter, Mr. Bickerton says that he was only able to collect materials for a "fragmentary sketch." He was a cultivated, well-read man, a man of most generous and simple nature, and one, too, never weary in well-doing, but too modest and retiring to have left behind him material for a biography. A member of the Society of Friends, and born in 1762, he was educated in Edinburgh, receiving his degree of M.D. at the age of 24. He had studied in Edinburgh for but three years, but apparently he had served a medical apprenticeship in Liverpool from about the age of 16. His thesis is dedicated to his maternal uncle, William Brownsword, and dated "Edinburgh, the Ides of June (June 25th), 7th day, 1786." The date, be it noted, is somewhat confused; the Ides of June—i.e., June 13th—fell on a Saturday in 1786 according to Old Style, which, however, was done away with in 1752. Rutter, apparently wishing to give in addition the modern date, omitted the orthodox 11 days, making June 13th June 25th, in accordance with New Style, so that one of his dates is Old Style and the other New. Mr. Bickerton points out that Rutter's claim to fame was not so much his medical knowledge as his "recognising and advocating the means by which progress alone is possible—viz., education and coöperation." It was this idea which led him to the foundation of the Medical Institution as a place, to use his own words, from which, "as from a common centre, very interesting information affecting the welfare of large portions of the community may be diffused in every direction." It is interesting, too, especially at this time, to note that Rutter looked forward to the influence of the institution in enabling Poor-law medical officers to obtain a fair remuneration for their services. Such a man was John Rutter, and we are grateful to Mr. Bickerton for having put on record even the little information which he has been able, after much labour, to gather concerning him, for Rutter was one of those not uncommon in our profession who acted after the old canon, "What doth the Lord require of thee but to do justly, and to love mercy, and to walk humbly with thy God."

CEREBRO-SPINAL MENINGITIS IN BELGIUM.

WE have received a copy of an official report presented to the Minister of the Interior and of Agriculture of Belgium by Dr. M. Henseval and Dr. R. Bruynoghe of the Public Health and Hygienic Service dealing with the outbreak of cerebro-spinal meningitis in that country during 1909. The report reviews briefly the distribution of epidemic cerebro-spinal meningitis in the world and the history of its appearances in Belgium since the year 1859. After 1900 cases appeared more frequently, and during 1909 52 cases were reported distributed throughout the country, as shown in a map appended to the report. In a few of these cases, however, the diagnosis appears to have been doubtful. The number of cases attained its maximum during May, June, and July; 34 of the patients were children, 8 were adolescents, and 10 were adults. Only 19 of the cases were established as due to the meningococcus by bacteriological investigations; 6 of them occurred in one district and among persons closely associated together. Dr. Henseval and Dr. Bruynoghe discuss at some length the prophylaxis and treatment of the disease. They insist upon the importance of the healthy carrier of the meningococcus in the dissemination of the disease. They admit the laborious character of the bacteriological examination necessary to establish the fact that a given individual is a carrier, owing to the fact that organisms superficially resembling the meningococcus are often present in the naso-pharynx. They also admit the difficulty in securing isolation of carriers even when they are established and state that some authorities have regarded such measures as impossible of realisation, a view which they dispute, since they claim that in many instances it is possible to find the carriers and to quarantine them. They recommend that the patients should be isolated, by preference in a hospital, and that special care should be taken to protect children and young people from contact with patients or with carriers. They also advise that the linen and all objects soiled by the patients should be

carefully disinfected. The nurse should wear a long overall, to be removed on coming from the patient's room. The naso-pharynx of the attendants should be frequently rinsed with a disinfectant solution. Attempts should also be made to disinfect the naso-pharynx of carriers by means of insufflations of dried anti-meningococcus serum or of pyocyanase. They strongly recommend the use of anti-meningococcus serum in the treatment of patients suffering from the disease. In the Belgian cases it was used for 15 patients, of whom 10 showed successful results, in spite of the fact that in some of them the serum was not given as early as is desirable. Of the patients who did not receive any serum, 24 out of 36 died, and among those who recovered 1 became deaf, 1 was left with strabismus, and 4 continued to suffer from paraplegia after the acute stage of the disease had subsided. The method of treatment which Dr. Henseval and Dr. Bruynoghe recommend is the withdrawal of 20 cubic centimetres of cerebro-spinal fluid by lumbar puncture and the injection through the same cannula of 20 to 30 cubic centimetres of serum. This process should be repeated for three or four days or even more. Supplies of serum from the Rockefeller Institute at New York and from other sources were placed by the Belgian authorities at the disposal of any medical man requiring it for the treatment of cases of the disease. The report affords an indication of the interest shown in matters of public health in Belgium and is a noteworthy addition to the literature of the disease. The value of the anti-meningococcus serum is illustrated by a case recorded at p. 1068 by Mr. J. J. Weaver, with a note by Dr. Percy Marsh.

RABELAIS THE PHYSICIAN.

AMONG the world's most remarkable men must be included Rabelais, romancist, physician, and ecclesiastic. Few beyond the medical profession associate the author of "Gargantua" with medicine and surgery, and fewer still with the Church. In the *Journal des Débats* we read, "Un Comité vient de se constituer à Montpellier en vue d'élever à Rabelais un monument commémoratif de son passage dans l'antique et illustre Faculté de médecine de cette Université." In view of this interesting announcement it is opportune to recall briefly Rabelais's connexion with the healing art. Of the early days of "one of the few great humorists of the world," as Mr. Saintsbury terms François Rabelais, we have nothing but tradition, but in 1519 we know from a deed of conveyance that he was a Franciscan. Five years later, by an indult of Clement V., he changed his order and became a Benedictine. In the year 1530 his connexion with Montpellier can be traced, and he then appeared in public in the habiliments of a secular priest. From this time his name is inseparably associated with the city, and in the gallery of the former professors of the University his portrait finds its place. He then turned his thoughts to medicine and entered the Faculty of Medicine at Montpellier in September, 1530, and became a Bachelor in the November following. The next year he was lecturing on Galen and Hippocrates. In 1532 he was at Lyons acting as physician to the Hôtel Dieu with a yearly salary of 40 livres, and finding time to edit the medical "Epistles" of Giovanni Manardi," the "Aphorisms" of Hippocrates, and "Ars Parva" of Galen. In 1534 Rabelais accompanied Jean du Bellay to Rome as his physician. The authorities at Lyons Hospital considering that their physician had absented himself without leave appointed a successor, but, like a commitment order in our courts, the decision was "allowed to lie in the office" until his return. Before this took place he was again in Rome with Bellay, who was now a cardinal. In 1537 Rabelais took his doctor's degree at Montpellier, lectured on Hippocrates, and made a public anatomical demonstration. In the troublous times towards the end of the reign of Francis I., Rabelais was living in Metz and discharging the duties of town physician at a salary of 120 livres. During this time he was in needy circumstances, but after the death of Francis the clouds passed and, returning to France, he became "le curé de Meudon," as he is generally known among his own countrymen. From this time until his death, which is supposed to have taken place in 1553, Rabelais was engaged for the most part upon those literary pursuits which have made his name immortal. The Comité before referred to invite sculptors to submit models before the first day of May next. For the guidance of competitors the Comité states that it proposes to expend 30,000 francs (£1200) on the work. Considering the fame of Montpellier's professor, there should be no difficulty in obtaining funds for a more ambitious project.

DURATION OF THE INFECTIVITY OF THE GLOSSINA PALPALIS.

IN THE LANCET of Jan. 22nd we furnished our readers with an abstract of Sir H. Hesketh Bell's official report on the administrative measures which had been carried out in Uganda under his directions with a view to stopping the spread of sleeping sickness. Chief among these measures was the compulsory removal of the entire population at the end of 1907 from the fly-infected zone around the Victoria Nyanza to a new location some miles back from the shores of the lake. It was confidently anticipated that this drastic procedure would have the effect of causing a great diminution of the disease, if not its entire disappearance from the neighbourhood, since in the absence of natives with trypanosomes in their blood the glossina could not become freshly infected, and the formerly infected insects would naturally tend to die out in the course of time. Among the papers which have been presented to the Royal Society recently by the Sleeping Sickness Commission—of which Sir David Bruce, C.B., F.R.S., is the leader, and Captain A. E. Hamerton, D.S.O., and Captain H. R. Bateman of the Royal Army Medical Corps, and Captain F. P. Mackie of the Indian Medical Service, the co-workers—is one dealing with an investigation into the question of the duration of the infectivity of the glossina palpalis after the depopulation of the lake shores. When the inquiry was begun a period of two years had elapsed during which no native had been allowed to live or work within two miles of the Victoria Nyanza, except at a few cleared landing places, and as regards the population of the islands in the lake they had all been removed for some months prior to the commencement of the investigation. It is obvious that until it had been clearly ascertained that the flies had ceased to be infective it would be unsafe to permit the zone around the lake to be re-inhabited. For the purpose of testing the condition of the glossina as to infection 12 experiments were carried out by feeding on healthy monkeys a large number of flies caught on the shores of the lake. In only one instance, where the flies had been collected at or near one of the cleared landing places, was the result negative; but in the remaining 11 experiments with flies collected from the vicinity of the lake the disconcerting discovery was made that the glossinæ had still the ability to infect, and did actually transmit sleeping sickness in each instance to the monkeys. Sir David Bruce therefore concludes that glossina palpalis on the uninhabited shores of the Victoria Nyanza can retain activity for a period of at least two years after the native population has been removed. The investigators were not able to account for this apparently prolonged period of infectivity, but they discuss in their paper a number of possible explanations. Only two of these,

however, are regarded by them as needing further consideration, viz.: (1) that the duration of the life of the glossina is more than two years, and that, therefore, flies which became infected before the natives were removed are still alive and capable of transmitting sleeping sickness; or (2) that the mammals or birds along the shores of the lake have become infected and so act as a reservoir of the disease. As to this latter view there is at present no experimental proof, for the injection of the blood of shore-birds and mammals into susceptible animals has so far yielded only negative results. Sir David Bruce and his colleagues, in another paper read before the Royal Society, have shown that the proportion of infected flies to those which are not infected must be small, for by experiment it is seen that in artificially infected flies only 1 in 60 displayed the phenomenon of late infectivity. In nature the proportion, it is thought, must be considerably less, probably not much more than 1 in 1000. It appears to us that if infected flies can live two years or more, there would be advantage in instituting measures for the destruction of the tsetse flies in the zone surrounding the Victoria Nyanza. We are aware that Dr. Bagshawe, director of the Sleeping Sickness Bureau, has characterised attempts to reduce the number of these flies in any locality as "a labour of Sisyphus." In the light, however, of the facts reported by Sir David Bruce and his co-workers we think that fresh consideration might be given to the subject. In THE LANCET of Feb. 12th we drew attention to Maldonado's method for destroying these insects, and as the process appears easy and costs little a trial might, perhaps, be given to it with a view of attempting to get rid of the surviving infected glossina in and around the shores of the great African inland sea.

DUELLING IN ITALY.

THIS "method" or "relic" of barbarism dies hard south of the Alps. A discreditable scene in the Chamber of Deputies in which the good faith of military men and Members of Parliament, not excluding their female relatives, was called in question, drew down on the accusing orator (one of the Extreme Left) not only a shower of indignant protests, followed by fisticuffs in the lobbies of the House, but no fewer than four challenges to mortal combat. In the first of these the pistol as the weapon for vindicating offended "honour" was ruled out by the seconds and the sabre employed. Twenty-four assaults between the principals (General Fecia di Cossato and Signor Chiesa) took place, in the last of which the General was wounded and a welcome opportunity afforded for bringing the encounter to an end. Ultimately the General and the civilian (the latter, as usual on these occasions, having proved the superior fencer) were reconciled, embracing and kissing each other in true Southern fashion; while the three "hostile meetings" still to come off were cancelled as the result of "amicable arrangement." The incident has demonstrated once more the absurdity of the duel—doubly absurd in a nationality which prides itself on its respect for humans life, even to abolishing capital punishment, but yet look calmly, even approvingly, on when two men, of high social or official standing, deliberately attempt to shoot or sabre each other. What chance is there for the crusade against the "accursed knife," the weapon of the poor, when the upper ten thousand freely resort to the pistol or the sword, under the formal conditions of "seconds" and "umpires," always with lethal intent—often, too, with lethal effect, as in the case of poor Felice Cavallotti, "the Shelley of Italian statesmen"? In truth, the better mind of Italy has at last intervened to put a stop to the practice, and committees of all ranks and of both sexes have organised a movement which, by making the duel a criminal offence, will bring Italy into line with her more civilised sisters, while making her consistent with herself in abolishing "capital punishment" not only on the scaffold but also on the greensward.

SOCIETY OF MEDICAL OFFICERS OF HEALTH: A PRESIDENTIAL ELECTION.

FOR the first time, we believe, in the history of the Society of Medical Officers of Health there has been more than one candidate nominated for the position of President of the society. At the election which took place on April 8th six Fellows of the society were nominated for the office. They included Dr. A. K. Chalmers, Glasgow; Dr. F. G. Crookshank, Barnes; Dr. T. Eustace Hill, Durham; Dr. E. W. Hope, Liverpool; Dr. W. G. Willoughby, Eastbourne; and Dr. J. T. Wilson, Lanark. After some discussion as to the method of election, which according to the articles of association of the society must be by ballot, the names of all the candidates but Dr. Crookshank and Dr. Willoughby were withdrawn, and the latter was elected by 55 votes against 29 given to Dr. Crookshank.

RECURRENT INTRACRANIAL PSEUDO-TUMOUR.

A SHORT time ago we published an annotation on certain cases of so-called pseudo-tumor cerebri, of which the clinical features were indistinguishable from those accepted by all as characteristic of intracranial neoplasms, but where subsequent pathological examination failed to reveal any trace of the latter. As the simulation of spinal tumour by a localised serous meningitis is now, especially since the work of Sir Victor Horsley, more widely recognised, it has been suggested that some such condition may account for at least a section of these intracranial cases, the clinical importance of which we do well not to under-estimate. The latest number of the *Neurologisches Centralblatt* contains a paper by Dr. Heinrich Higier of Warsaw on a seemingly unique case of this description, where the symptoms disappeared entirely, and after an interval of 13 years appeared again, to disappear completely once more. There came under the observation of Dr. Higier in 1893 a Jewish boy, aged six years, who complained of paroxysmal headache, vomiting, giddiness, and attacks of transient blindness; he also suffered from typical attacks of Jacksonian epilepsy beginning in the right great toe, and from paræsthesiæ on the right side of the body. On examination there was right-sided hemiparesis, with diminution of sensibility, and a right ankle clonus; there was also paresis of the left sixth cranial nerve, and pronounced double optic neuritis. Antispecific treatment was followed by no observable amelioration; but after about six months the symptoms gradually disappeared one by one, and no trace whatever of disease was left. In 1904 the youth was in perfect health, and had been so for ten years. In May, 1906, after a trip to London, he began to complain again of diffuse headache, lassitude, vomiting, and uncertainty in walking. He was found to have again a right-sided hemiparesis, with exaggerated deep reflexes and an extensor response, and marked double optic neuritis with diminution of visual acuity. Nystagmus, intention tremor, and sphincter impairment were all absent. Antispecific treatment was energetically applied, but without avail, and an exploratory operation was proposed. Nevertheless, in December of the same year, for an unexplained reason, the symptoms slowly but steadily diminished in intensity, and in less than three months the sole indication of any intracranial disease was residual pallor and fluffiness of the optic discs. In June, 1909, the patient reported himself in robust health. Of various possible diagnoses that suggest themselves for this case there is none that is satisfactory, although the writer passes several in careful review. One or two somewhat

analogous cases are to be found in the literature, notably one by Hoppe, where the results of a necropsy proved to be negative. It is not, of course, permissible to entertain the idea of intracranial pseudo-tumour if the effects of syphilis, tuberculosis, severe anæmia, accident, and so on, cannot be excluded, or if encephalitis or hydrocephalus can be diagnosed, or if any subsequent pathological examination is incomplete. It is precisely this differential diagnosis of hydrocephalus or encephalitis that is often so fraught with difficulty, for these conditions sometimes simulate tumour closely, and if in addition chronic serous circumscribed meningitis of the cerebrum turns out to be substantiated it may be, according to Dr. Higier, that pseudo-tumor cerebri will become a pseudo-diagnosis.

OCCUPATION MORTALITIES.

IN a recent number of the Transactions of the Scottish Faculty of Actuaries [1] there appears a paper by Dr. James C. Dunlop, of the General Register Office, Edinburgh, on the influence of occupation on mortality, in which he has endeavoured to elaborate the observations contained in Part 2 of the supplement to the 65th annual report of the English Registrar-General. In an introductory note an interesting account is given of previous investigations on occupation mortality in this country, from the first essay by Dr. Farr in 1865 down to the most recent essay by Dr. Tatham in 1908, the latter work being justly characterised as "the most important contribution to the subject which has yet been published." For comparison with these reference is usefully made to the researches on the same subject by Dr. Bertillon of Paris (1889–95), and to those recorded for Switzerland in the Swiss Bureau de Statistiques (1871–90). In an essay expressly written for scrutiny by actuarial experts the author appropriately discusses the probability of error from paucity of data, as well as the limitations inseparable from statistical investigations of this kind, giving particulars of the methods adopted by him in dealing therewith. Referring to his own work on occupation mortality in Scotland, based on the population of 1901, and on the deaths in that year and in the years respectively preceding and succeeding the census, Dr. Dunlop endeavours to justify his departure from the expedient adopted in previous Scottish and English reports for measuring differences in the healthfulness of occupations —viz., that of computing for each of them the comparative mortality figure, his contention being that "the Scottish numbers were too small, and the consequent error too large to warrant such concise deduction." In place of this method the probable errors of the death-rates have been calculated and the several occupations have been arranged in six groups according as their corrected death-rates corresponded to or differed from the general rates of males in each of two periods. In addition to the foregoing Dr. Dunlop has used in this paper two other methods of comparison—viz., (1) the expectation of life in each occupation and (2) the probability of reaching the age of 65 years. As regards the exceptional value of the life-expectation method for comparative purposes there is practical agreement among vital statisticians. On the other hand, if we may judge from the experience of Somerset House, the comparative mortality method still in vogue on this side the Tweed would seem to have practical advantages not possessed by other and more complicated methods. In the course of his pamphlet Dr. Dunlop gives the principal particulars of the mortality observed in the more important occupations. For specified reasons he abstains from comment on the diseases causing this mortality, but, inasmuch as this information has already been given in the last supplement of the English Registrar-General, the omission is not a serious one. What constitutes the most interesting feature in the present work is the fact that the experience of France and of Switzerland is frequently laid under contribution for comparison with that of Scotland and England, and this alone would have fully justified its publication. As before stated, the selected occupations are here arranged in six groups. Comparing the first group with the last, we note that the first or healthiest group contained the chief professional occupations—e.g., the clerical, the legal, and the medical profession. The exceptional healthiness of the clergy is everywhere accepted as an established fact. They enjoy the highest expectations of life, and the highest probability of attaining the age of 65 years. In all the English and Scottish studies, as well as in the studies of France and Switzerland, the clergy have invariably been credited with a remarkably low death-rate. Lawyers also would appear to be a very healthy group. Their life expectation exceeds that of the general community by 2·7 years. Their probability of reaching the age of 65 is more favourable than that of other men, and so is their comparative mortality figure. Although, according to Parisian experience, lawyers enjoy fairly long lives, Swiss experience, on the contrary, shows them to suffer a higher rate of mortality. According to Scottish experience, the medical profession suffer a mortality somewhat in excess of that of other men. In Paris the death-rates of our profession are low, whilst in Switzerland, on the other hand, the reverse holds true. In the last or sixth of Dr. Dunlop's groups are included several occupations of a casual or intermittent character which are calculated to offer refuge to the derelicts of other occupations. To this fact, rather than to the hazardous nature of employment, is to be attributed the heavy mortality experienced by those included in this group. In Group 6 are classed coal-heavers, messengers, dock labourers, costermongers, and general labourers, all of which experience a death-rate greatly in excess of the average, and their expectation of life is less than that of other males by from two to eight years. General labourers are the most unfortunate of all; their expectation of life at age 25 is only 28 years, and is therefore in defect of the average by more than nine years.

COMPARATIVE STRENGTHS OF SOME COMMERCIAL SOLUTIONS OF EPINEPHRIN.

EPINEPHRIN, the active principle of the suprarenal glands, is marketed under various names in the form of a solution, but clinicians hold conflicting views regarding the size of the dose necessary to produce a given physiological effect. In some cases negative results have unexpectedly been obtained, and as a consequence a certain amount of distrust has arisen regarding the effectiveness of some solutions of the drug. A series of quantitative studies of the relative physiological activity of some commercial solutions of epinephrin has been conducted by Dr. W. H. Schultz,[1] who found that of the seven different brands of epinephrin examined only three possessed an activity that equalled the standard. The method of comparison adopted was based on a previous investigation which showed that a pure sample of epinephrin furnishes a trustworthy standard in assaying vaso-constrictor substances. A solution of the pure base was prepared in the laboratory, showing but a trace of colouration and possessing a maximum physiological and optical activity and keeping properties that met all the requirements of a standard.

[1] Bulletin No. 61, Hygienic Laboratory, United States Public Health and Marine Hospital Service, Washington, D.C., 1910, pp. 30.

From the data collected it seems that the physiological activity of all epinephrin-like bodies can be assayed by the blood pressure method and their efficiency expressed in terms of the pure epinephrin base. It has been found that dogs yield the most constant and uniform results, the method used being that described in Bulletin No. 55 of the Hygienic Laboratory. Four of the seven brands of epinephrin solution under examination were found to vary from 3·75 to 71 per cent. of the required activity, those of weak strength being more or less worthless, and perhaps dangerous, from the physician's point of view. Some solutions, though showing a high degree of activity upon opening the original package, quickly deteriorated in spite of the extra precautions taken to guard against conditions known to further this process. Two of the solutions, adrenalin solution and supracapsulin solution, were found to be equal to the standard in activity. An examination of synthetic suprarenin solution showed it to be only one-half as active as the standard. The keeping properties of solutions of the synthetic substance are apparently very good when kept sealed in the original package, but not when diluted, even though kept under the most suitable conditions. This is shown by the rapid colour change and by an appreciable loss in physiological activity. Dr. Schultz made some preliminary experiments on the relation existing between the different shades of colour developed in solutions of epinephrin and their respective physiological activity. He found that the method of expressing the amount of colour in units of the ordinary colorimeter is unsatisfactory, for not only do the solutions develop different degrees of depth of colour, but more than one tint is involved. In the presence of sulphites and other deoxidising agents a solution may show but little colour, even when exposed to air and light, while at the same time it may possess but little vaso-constrictor action. In the absence of such abnormal conditions the strength of the solution is roughly in inverse proportion to the colour that usually develops in solutions of epinephrin upon standing. The colour is not always a safe criterion by which to judge the value of a solution of epinephrin. The presence of a precipitate points to the probability of serious deterioration in activity.

THE INTERNATIONAL COMMITTEE FOR POST-GRADUATE COURSES.

IT will be remembered that during the Congress of Medicine last year at Budapest an international committee was formed for the promotion of post-graduate studies in different countries, largely through the initiative and organising ability of Professor R. Kutner of Berlin, secretary of the committee, and under the presidency of Dr. Waldeyer, also of Berlin. A set of papers has now been circulated containing information upon the work of the committee, from which we learn that the board of management includes, besides the two gentlemen we have mentioned, Professor Landouzy of Paris, Geheimrat Professor Dr. v. Rein (St. Petersburg), and Dr. F. W. Pavy, and that Dr. Pavy's British colleagues on the committee are Dr. W. A. Jamieson of Edinburgh, Fleet-Surgeon E. B. Pickthorn, with the addition of Sir Benjamin Franklin, K.C.I.E., and Sir Havelock Charles, K.C.V.O., specially for India. One of the papers contains the statutes of the committee, which define its objects and organisation. Amongst the former are included the collection of information concerning the facilities for post-graduate study existing in different countries, the exchange of eminent teachers for the purpose of giving instruction to foreigners on important new methods, the arrangement of conferences in connexion with international medical congresses, statistical work, and the promotion of study tours in foreign countries. (We published full details of the organisation of the committee in THE LANCET of Sept. 11th, 1909, p. 813.) The remaining papers contain respectively a list of questions to be addressed to the post-graduate associations in each country concerning the ordinary academic and clinical instruction on all subjects of the medical curriculum available therein, the legal regulations for the courses of study and examinations, and the organisation of systematic instruction for military surgeons. A further list of questions asks for detailed particulars concerning the post-graduate courses in existence, the fees requisite for their use, and so on. The final paper contains the agenda for an extraordinary meeting of the committee which is to be held during the centennial celebration of the University of Berlin. They deal with the coördination of the information which will result from the committee's inquiries and the possible alteration of the lists of questions to be circulated, the organisation of an international information bureau concerning post-graduate facilities in different countries, and the amount of the subscriptions to be contributed by individual countries to the international committee, which we imagine will not be on a uniform scale. The office of the committee is situated at Kaiserin Friedrich-Haus, Luisenplatz 2–4, Berlin, N.W. 6.

THE ARTHRITIC DIATHESIS.

AT a meeting of the Academy of Medicine of Paris on March 8th last Sir Dyce Duckworth read a paper entitled "Étude Clinique sur les Particularités de la Diathèse Arthritique." He referred mainly to the arthritic diathesis in relation to gout, which he regarded as an endogenous malady following in the course of errors of metabolism in subjects disposed to "arthritism," and to neurotic manifestations in certain phases. He referred to the characteristics of the "gouty temperament," such as a tendency to urinary concretions, to asthma, and to eczema. He also drew attention to the digestive peculiarities of gouty subjects, such as the inability to digest certain fruits, and the predisposition to gouty attacks after the ingestion of tomatoes, rhubarb, lemon, or acid wines. He also mentioned another phase of the subject which has been especially studied by French physicians—namely, the remarkable immunity of the arthritic constitution to tuberculosis. In the gouty subject the soil is particularly unfavourable, and if infection does occur the progress of the disease is slow and has a marked tendency to arrest with fibrosis and chalky formations. Sir Dyce Duckworth's paper is published in the *Journal de Médecine de Paris* of March 26th.

THE WORK OF THE PELLAGRA INVESTIGATION COMMITTEE.

Dr. Louis Sambon, in charge of the Field Commission of the Pellagra Investigation Committee, has sent to the committee from Bergamo, where he is making his headquarters, a short report of the proceedings. Dr. Sambon, accompanied by his assistant, Mr. Amoruso, left London on March 20th, and joined Captain Siler and Mr. Baldini, who were already in Italy. After communication with the secretary of the Pellagra Commission of Milan and interviewing those who were already working at pellagra, an excursion was made to Trescore, where the disease is said to be very prevalent. The cases were found along the course of a mountain stream, the Tadone, the bed of which teemed with the larvæ or pupæ of simulium. Some of these were collected and sent to Mr. E. E. Austen, who is acting as entomologist to the committee. Professor Balp and Dr. Perrico were at this juncture detailed by the Bergamo Pellagra Commission to assist the British Committee, and Dr. Perrico accompanied Dr. Sambon and

Mr. Amoruso to Brusaporto, while Captain Siler and Mr. Baldini went to Albano and Torre dei Reveri. At Brusaporto 84 cases of pellagra were found in a population of 1000, and Captain Siler reported numerous cases at Albano, but none at Torre dei Reveri. The countryside is sorely afflicted with typhoid fever, measles, and diphtheria, while in Albano rabies is said to be present.

SUCCESSFUL RESECTION OF THE INTESTINE FOR MESENTERIC THROMBOSIS.

IN the *Boston Medical and Surgical Journal* of March 17th Dr. E. A. Codman has reported what appears to be the ninth successful case on record of intestinal resection for mesenteric thrombosis. A man, aged 45 years, was admitted into the Massachusetts General Hospital on Oct. 21st, 1909. His illness began three weeks before with dull abdominal pain. The pain persisted in the upper abdomen on the left side. Acute exacerbations lasting about an hour occurred. The pain was increased by exercise and by eating. The bowels acted every day until the last three days. On admission the abdomen was full and somewhat rigid but not tender. There were a leucocytosis of 35,000 and a systolic murmur. On Oct. 23rd the patient was seized with severe pain in the left upper abdominal quadrant. The pain was constant, but attended with paroxysms lasting 10 to 15 minutes. After two hours the abdomen had the rigidity of peritonitis, the patient became intensely pale and covered with cold perspiration, and the pulse was rapid and thready. Perforation of some viscus into the general peritoneal cavity was suspected. Under ether an indistinct mass was felt to the left of the umbilicus. A 6-inch incision was made at this spot and much bloody fluid was found in the abdomen. Beneath the incision were two dark-red coils of small intestine, evidently in a condition of hæmorrhagic gangrene. A search was made for other areas of infarction, but none were found. Resection of the affected area was performed. Much difficulty was experienced in tying off the mesentery, which was œdematous and friable. As the upper part of the jejunum was affected end-to-end anastomosis was performed. For several days the patient was in a critical condition with a bad pulse, bloody diarrhœa, and hæmatemesis. Typical acute gastro-mesenteric obstruction developed and was relieved by lavage and change of position. The leucocytosis did not begin to diminish until 10 days after the operation. During convalescence there appeared to be some free fluid in the abdomen. The portion of intestine removed was 4 feet long, and its veins were thrombosed. The middle 2 feet were dark red, and a foot on each side was of doubtful vitality. About 214 cases of mesenteric thrombosis have now been recorded, of which 50 were operated on. Although the mortality of operation is very great it offers a better chance than expectant treatment. The diagnosis before operation is almost impossible.

REGIONAL AND MYOCLONIC CONVULSIONS.

ONE of the most distinctive and at the same time least known features of genuine epilepsy is the occurrence of jerks or jerk-like movements without loss of consciousness. While they are rarely complained of spontaneously by the patient, it is often found on careful inquiry that he has suffered from them for years, usually the first thing in the morning, or during the night, and particularly for a longer or shorter time before the first paroxysmal fit. According to Dr. L. J. J. Muskens of Amsterdam, who devotes an article to their consideration in *Epilepsia* for 1909, they are present in the early stages of the disease more frequently than any other minor symptom, and are indeed perhaps as common as the familiar frontal headache of the pre-epileptic period. Sometimes these jerk-like phenomena are all that is ever noted. They are either unilateral or bilateral, and affect some definite region of the body; sudden adduction or extension of one or both arms, and sudden flexion or extension of the trunk are the commonest. In no fewer than 103 out of 150 female epileptics, and in 82 out of 150 male, regional convulsions were present at some or other period of the disease. They correspond to what Sir William Gowers has described as multimuscular contractions, and are rarely localised in one muscle or part of a muscle. A comparison of their main clinical features with those described as myoclonus shows certain special points of similarity in the two, and leads to the conclusion that each should be considered a subtype of genuine epilepsy. A compensatory relation between regional convulsions and complete epileptic fits can often be discovered. It is very well known that healthy individuals on going to sleep or during the night often wake up with a sort of jerk, and on the other hand epileptics are often met with who suffer from sleeplessness brought on by a continual waking up from their sleep by repeated jerking movements. Why these times should be associated with the appearance of jerks and regional minor discharges we are at a loss to know. Sometimes the jerks occur with peculiar violence while the individual is dressing. In view of the curious indifference of the lay mind to this pathological condition until the major fits have established themselves, their early diagnostic significance ought to be impressed on the general practitioner.

LUMBAR PUNCTURE IN MENINGITIS.

ALL who have much experience in the treatment of children are agreed that lumbar puncture is frequently of great value in diagnosis, especially in cases of meningitis, and in the present issue of THE LANCET we print a careful paper by Dr. G. Stirling Landon on this subject, based on a large number of cases which he had observed himself. 50 of the cases were suffering from meningitis, and about half of these were tuberculous in nature. Four of the cases suffered from chronic hydrocephalus and four from acute poliomyelitis. There are some who regard lumbar puncture as dangerous, but if due care be taken the risks are slight, except when there is partial or complete closure between the cranial and spinal portions of the cerebro-spinal canal, and in this case the distended brain may be pushed down into the foramen magnum and a fatal result may ensue. It may also be mentioned that the risk of lumbar puncture is decidedly greater in cases of cerebral tumour than in cases of meningitis. The most important clinical characters of the cerebro-spinal fluid are its cytology and its bacteriology. In the cytology the most critical matter is to determine whether any leucocytosis is mononuclear or polymorph, for it may be said that if the effusion is polymorph in character the leucocytosis is probably caused by a microbic infection rather than by tubercle, though this rule is by no means without exception. It has been suggested that a polynuclear effusion may result from the irritation caused by the needle in making the lumbar puncture. If this be so, subsequent tappings would be vitiated. The most conclusive of all positive results which can be obtained from examination of the withdrawn fluid are furnished by a bacteriological examination. The fluid itself forms an excellent culture medium and by this means organisms may be discovered which would otherwise have been missed. In the cases of tuberculous meningitis the organisms were found in all the 14 cases which were examined for it. It may be said that while positive results in lumbar puncture, especially the identification of a causal organism, are of great value, with most of the tests negative results are of little importance. Too much must not be expected from lumbar

puncture in the way of treatment, but in a certain number of cases recovery was apparently due to its repetition. Dr. Landon's paper is of distinct value, and an extensive bibliography will render it easy for any reader to study the subject more fully.

THE OCCURRENCE OF ADVENTITIOUS SOUNDS IN THE NORMAL CHEST.

UNLESS the normal sounds heard on auscultation of the chest are fully understood errors in diagnosis are likely to occur. For instance, the breath sounds heard immediately below the clavicle on the right side instead of being of the usual vesicular nature may be blowing or broncho-vesicular in character, although no morbid condition is present; so also occasionally adventitious sounds may be heard which are not due to disease. In another column we publish a letter from Dr. R. D. Rudolf of Toronto on this subject. Dr. Rudolf read a paper at the Winnipeg meeting of the Canadian Medical Association in August, 1909, in which he pointed out that it is usually considered and taught that in auscultating the normal chest nothing should be heard over the respiratory tract but the breath sounds and the vocal resonance, and as a rule this is undoubtedly true. In many chests, however, on careful auscultation, especially during a full inspiration, there may be heard fine or even medium sized crepitations. They are probably due to the unfolding of partially collapsed portions of the lungs. In out-patient practice it is a common experience to find that many patients, especially women, rarely expand their chests fully. When shown how to do so, during the forced respiration crackles may at first be heard over the bases of the lungs. The same result is less commonly experienced in examining the apices of the lungs, and unless this fact be remembered the crackles first heard when the patient is told to "breathe deeply" may be mistaken for signs of early tuberculous infiltration. Dr. Rudolf rightly mentions, however, that these sounds are chiefly heard along the edges of the lungs, and especially just behind the cardiac notch. The fact that they readily clear up upon full respiration, the absence of causes of œdema, and the want of all symptoms and signs of respiratory disease usually make it an easy matter to recognise their true nature. If all children were taught to respire fully such signs would be very rare.

THE TREATMENT OF DRY ARTHRITIS BY INJECTION OF VASELINE.

ABOUT six years ago Th. Rovsing of Copenhagen treated two cases of dry traumatic arthritis of the hip by vaseline injections, with results of so favourable a character as to encourage him in the application of the same method to other forms of joint disease without effusion. His latest paper on this subject[1] summarises results obtained by the injection of sterilised vaseline into 35 joints, results which have been observed over periods of at least 18 months following the injection. These 35 joints correspond to a total of 30 cases, in 5 of whom two joints were treated. In one group of 7 cases of gouty arthritis and arthritis deformans (multiple symmetrical arthritis with swelling and exacerbations) the results were in the main disappointing; injection was followed by a recrudescence of inflammatory change, and the vaseline appeared to act as an irritant. Rovsing is disposed to think that the treatment is inapplicable to these types of arthritis, except in cases where all active inflammation has died out and a dry joint remains; and he says that when fluid is found in a joint of this (inflammatory) type by puncture vaseline ought not to be injected, but that if the joint yields no fluid a small quantity of vaseline, insufficient to distend the synovial capsule, should be introduced. A second group, comprising 19 cases, is labelled "traumatic dry arthritis"; this includes senile osteo-arthritis of the hip and knee, as well as chronic arthritis following upon definite injury or continuous overstress. Puncture of the joint in such cases discovered an absence of synovial fluid, and injection of vaseline produced almost uniformly good results. Rovsing accounts for this by suggesting that the vaseline takes the place of the absent synovial fluid as a lubricant. His success in these cases encouraged him to apply his method in four cases in which arthrotomy and arthrectomy were practised for the relief of chronic traumatic arthritis; here also he obtained good results. In many of his cases he claims to have diminished pain and to have increased the range of mobility of the joints treated. Sterilised yellow vaseline is used, in quantities varying with different joints; for the hip-joint 20 to 25 cubic centimetres, for the knee 10 to 12 cubic centimetres, for the shoulder about 15 cubic centimetres are recommended. The hip should be exposed by incision, and the temporo-maxillary joint needs a similar precaution; the knee and shoulder may be approached by direct puncture. A special form of trocar with cannula is used, which can be screwed on to collapsible tubes of vaseline; the use of this instrument enables the operator to ascertain whether synovial fluid is present within the joint before the injection is made. Similarly, if no blood flows through the cannula after puncture it proves that no vessel is opened and that vaseline emboli need not be apprehended.

THE Surgical Section of the Royal Society of Medicine will hold a debate on the Present Position of the Treatment of Syphilis on Tuesday, May 10th, and Tuesday, June 14th, at 5.30 P.M. Mr. J. Ernest Lane will open the debate, and Sir Jonathan Hutchinson, Dr. Alexander Fleming, and Mr. Arthur Shillitoe are amongst those who have promised to take part. The debate will be held in the Botanical Theatre at University College. Gentlemen wishing to speak in the debate are requested to send their names as soon as possible to the honorary secretary, Mr. J. Hutchinson, 1, Park-crescent, Regent's Park, London, W.

THE Hon. Sir John Cockburn, K.C.M.G., M.D., will lecture to the Royal Sanitary Institute, 90, Buckingham Palace-road, London, S.W., on the Public Health Aspect of Food-supply in the Colonies on Wednesday, April 20th, at 5.15 P.M.

A LARGE sum of money has been placed at the disposal of a prominent official of the British Dental Association in order that that body may put upon a working basis a scheme of dental treatment which is to be national in its scope.

DONATIONS AND BEQUESTS. — Mr. Cedric Houghton of Colwyn Bay has left by will £500 to the Preston and County of Lancaster Royal Infirmary and £300 to the Chorley Dispensary and Cottage Hospital.—The late Miss Emily Miller has left a sum of about £15,000 for charitable purposes. Subject to the payment of duties, one moiety is to be paid to the North London Consumption Hospital and one moiety to Dr. Barnardo's Homes.—Under the will of the late Mr. Jacobus Bernardus Gelder, the Great Northern Central Hospital, Holloway-road, N., and the Association for the Oral Instruction of the Deaf and Dumb will each receive £1000. Subject to certain interests, the sum of £6000 is to revert to the Great Northern Central Hospital.—Mrs. Martha Sophia Webb has bequeathed £400 to Addenbrooke's Hospital, Cambridge.

REPORT OF INQUIRY INTO THE QUESTION OF DEATHS RESULTING FROM THE ADMINISTRATION OF ANÆSTHETICS.[1]

ON Saturday last the Departmental Committee on the Law Relating to Coroners, which a fortnight ago issued its report upon the general matters included in the reference,[2] issued a further report dealing with the whole question of deaths resulting from the administration of anæsthetics. It is signed by all the Commissioners, we are glad to announce, for many of the points which are dealt with have been the subject of acrimonious discussion. We print the report in full and comment in a leading article upon the unanimous recommendations.

DEATHS RESULTING FROM THE ADMINISTRATION OF ANÆSTHETICS.

To the Right Honourable Winston Leonard Spencer-Churchill, M.P., one of His Majesty's Principal Secretaries of State.

SIR,—1. Pursuant to the Secretary of State's letter dated December 24th, 1908, and in connexion with our inquiry into the law relating to coroners and the practice in coroners' courts, we, the undersigned, have investigated the question of deaths resulting from the administration of anæsthetics. Many of the witnesses, coroners and others, who were called to give evidence on the general subject of our inquiry, incidentally gave us useful information on the special question of anæsthetics. We examined, with particular reference to anæsthetics, three leading London anæsthetists, Dr. Hewitt, Dr. Dudley Buxton, and Dr. Silk; some eminent surgeons, as, for example, Sir Victor Horsley, Mr. Pepper, of St. Mary's Hospital, and Mr. Clinton Dent, of St. George's Hospital; physicians who had devoted special atttention to anæsthetics, namely, Sir Lauder Brunton and Dr. Waller; and leading dentists, namely, Mr. Matheson and Mr. Tomes. We also had the evidence of the Secretary of the Incorporated Society of Extractors and Adaptors of Teeth, Limited, Mr. Butterfield, and of a prominent member of that society, Mr. Bowen. Finally, Sir Donald MacAlister, the President of the General Medical Council, kindly attended our Committee and gave us the views of the Council, and informed us of the steps taken by them to make the study of anæsthetics a necessary branch of the medical curriculum.

2. Dr. Hewitt gave us the statistics, extracted from the reports of the Registrar-General, as to deaths under anæsthetics for the 40 years from 1866 to 1905. They rose from 5 in 1866 to 155 in 1905. In the year 1897 there was a sudden unexplained rise to 126 deaths as compared with 70 in the previous year. But, with this exception, there has been a steady progressive increase in fatal accidents during the period in question. According to a return* furnished by coroners for the year 1908, the deaths under anæsthetics reported to them amounted in that year to 235.

3. We desire to point out that no absolute deductions can be drawn from these figures. In the first place there is no duty imposed on anyone to report a death under anæsthetics administered for any surgical or medical purpose. There is therefore no guarantee that every such death is reported to the coroner, or even notified as such to the registrar of deaths. Secondly, there is an important distinction to be drawn between death *from* an anæsthetic, and death *under* an anæsthetic. For example, a person under an anæsthetic may die from the action of the anæsthetic, or from surgical shock, or from hæmorrhage, or from a combination of these or other causes. So again a person under an anæsthetic may die from some accident consequent on its administration—e.g., asphyxia through the tongue slipping back, or regurgitation of food. Without a detailed investigation of each case it is impossible to say how far the anæsthetic was or was not the cause of death, or whether it even contributed to it. Thirdly, we have no statistics to show the ratio between the number of operations performed and the number of deaths under anæsthetics. This much we know, that, thanks to Lord Lister and to the system of aseptic surgery, a vast number of operations are now undertaken with success which a few years ago no one would have dared to do, operations without which patients must inevitably die or linger out their lives often in great agony. Abdominal surgery and brain surgery are both quite modern developments.

4. Still, when all these sources of error are allowed for, we have the fact that there is an increasing number of deaths under anæsthetics, and that in the opinion of experts a certain number of these deaths are due to preventable causes. A certain number of deaths are inevitable, whatever the care and skill may be with which the anæsthetic is administered.

Anæsthetics, like all other poisonous drugs, act differently on different constitutions. The idiosyncrasy of the patient is a factor which cannot be eliminated. Again, a person may be suffering from disease, *e.g.*, the status lymphaticus, which a skilled examination may fail to detect but which may greatly increase the risk. But in the interests of humanity it is of the first importance that accidents under anæsthetics should be brought down to the irreducible minimum.

We think that every death under an anæsthetic should be reported to the coroner, but we do not think that the coroner should in every case be bound to hold an inquest. He should have a discretion to decline to hold an inquest when he is satisfied on inquiry that the anæsthetic was necessary and was administered with due care and skill. The certificate of death should always state that the deceased died while under an anæsthetic. We understand that it is the usual practice for the medical man in charge of the case to report the death to the coroner direct. This is obviously the most satisfactory procedure, but in addition we think that the registrar of deaths should be required to forward to the coroner particulars of all such cases of deaths under anæsthetics as come to his knowledge.

5. As the law stands at present, the administration of anæsthetics is under no regulation. Although a man cannot sell a glass of beer to another without a licence, he may drug that other person to his heart's content, without let or hindrance from the law. Apart from any criminal intent, a bonesetter, or a beauty doctor, or a quack of any kind is as much at liberty to administer an anæsthetic to his patient for the purpose of an operation as a qualified medical anæsthetist. If an accident happens as a result of the administration, the fact that the person administering the anæsthetic was not qualified might, of course, be material as bearing on the question of negligence, civil or criminal.

We think that this unregulated state of affairs constitutes a serious menace to the public, and that the administration of anæsthetics should be carefully regulated by law. We proceed now to consider the different classes of anæsthetics, and the regulations which in our opinion should be applied to them.

6. Anæsthetics are either general or local. Dealing first with the general respirable anæsthetics the administration of which produces complete unconsciousness, and always involves a possible risk to life, we strongly urge that it should be made a criminal offence for any person to administer them who has not professional qualifications, or is not acting under the personal supervision of a person so qualified. We consider that the public ought to have the guarantee of professional training, and the further guarantee afforded by the administrator belonging to a recognised profession, with a high sense of responsibility, and under the disciplinary control of the General Medical Council.

7. General respirable anæsthetics fall into two categories to which somewhat different considerations apply, namely, nitrous oxide gas on the one hand, and, on the other, anæsthetics such as chloroform, ether, ethyl chloride, and the like.

Nitrous oxide gas is available only for operations of brief duration, and is the anæsthetic largely used in dental surgery. It is a very safe anæsthetic, and its effects quickly pass off. It requires, however, skill in administration and a knowledge of how to deal with certain common causes of danger which may occur, as, for instance, that of the tongue slipping back. Registered dentists have always freely administered it without medical assistance. It would be impossible to deprive existing registered dentists of their right to use it for dental operations, and, as regards the future we do not think that the right should be interfered with. All such dentists have now to undergo a good preliminary medical

[1] Presented to Parliament by command of His Majesty. Cd. 5111. London: Eyre and Spottiswoode, Limited. 1910. Price 1d. Pp. 8.
[2] THE LANCET, April 2nd, p. 942; April 9th, p. 1009.
* See Appendices.

training, and, if provision is made that this should include a course of instruction in the administration of gas as a compulsory part of the training, we think that the public would be sufficiently protected.

8. One point we desire to emphasise. We have had evidence that many of the accidents which have occurred in connexion with the use of nitrous oxide gas occurred when the same person both administered the gas and performed the operation. We think that in no case should one person attempt both to administer the gas and operate. If a medical man is not employed to administer the gas, the dentist should have the assistance of another registered practitioner for this purpose. When the patient is a woman, it is obviously important for the protection of the dentist, as well as for the safety of the patient, that a third person should be present. Single-handed operations under anæsthetics have given rise to several false charges of assault. This, however, is a matter which can be better dealt with by a professional byelaw, than by direct legislation.

9. We have considered carefully the representations of the Incorporated Society of Extractors and Adaptors of Teeth, who urged their claim to continue to be allowed to administer anæsthetics. The Secretary of the Society in his evidence told us that his Society had obtained returns from its members which showed that in England there had been 1,249,167 administrations of general anæsthetics by members of the Society, with only one fatal accident, and in that case the anæsthetic administered was ethyl chloride; there had not been a single accident with nitrous oxide gas. We have, of course, no means of testing these figures; but, even if not wholly trustworthy, they bear strong testimony to the safety of nitrous oxide gas. Still, after giving due consideration to this evidence, we remain of opinion that the public safety requires the guarantee of a professional qualification. No doubt many members of this Society are skilful anæsthetists, but, short of recognising a purely voluntary and uncontrolled Society as a branch of the medical or dental profession, we do not see that it is possible to draw any distinction between a member of the Society and any other member of the public at large. As the Secretary admitted, if a member of the Society is expelled for malpractices, he can still go on practising as before. The dental profession is not a close one. Any one can enter it who can comply with its very reasonable educational requirements.

Moreover, we do not think that the prohibition of the use of general anæsthetics would inflict any hardship on the members of the Society, because we gather from the evidence that they are, to an increasing extent, voluntarily giving up the use of nitrous oxide, and are using in its place cocaine and other local anæsthetics.

10. Somewhat different considerations apply to the anæsthetics of longer duration which are required for the more serious surgical operations. For such operations ethyl chloride is occasionally used, but the anæsthetics mainly relied on are chloroform and ether or combinations thereof, with or without alcohol. When pushed to any extent they act directly on the respiratory centre and the heart, and a new element of danger is introduced. Both chloroform and ether have peculiar advantages and disadvantages. Chloroform is less distressing to the patient; he goes under its influence more quickly than under ether, the period of excitement is less prolonged, and as a rule the symptoms on recovery are less unpleasant. Greater immobility is also obtained, and this is sometimes important to the surgeon; but the margin between safety and danger is narrower. Ether, on the other hand, is very much safer as regards its effects on the heart and respiration. One witness went so far as to say that it was seven times safer than chloroform. But in many cases it is unsuitable. It is unsuitable for the very young and the very old, and for any persons who suffer from bronchial troubles. Sometimes chloroform is given in combination with ether, and sometimes chloroform is given first with ether to follow. Great responsibility rests on the anæsthetist in choosing the anæsthetic for a particular operation. He has to consider the patient's constitution and state of health as well as the nature of the operation, and the safety and comfort of the patient largely depend on the anæsthetist's skill and experience.

In connexion with the employment of nitrous oxide gas we expressed a strong opinion that the same person should not administer the gas and perform the operation. This principle applies with increased force to such anæsthetics as chloroform or ether. But in the case of urgent surgical operations we recognise that no hard and fast rule can be laid down. In cases of emergency, as for instance in the case of a railway or machinery accident, the medical man on the spot must do his best with such assistance as he can get. Dental operations requiring prolonged anæsthesia are never of such urgency that the presence of a medical man should be dispensed with. The accidents which may occur during the administration of these anæsthetics require full medical knowledge to deal with them. The anæsthetist must be always on the watch, and must be prepared to use artificial respiration, or even in extreme cases to resort to such an operation as tracheotomy. We are of opinion, then, that the administration of those anæsthetics the effect of which is of prolonged duration should be confined to qualified medical men.

11. The question of local or regional anæsthetics is more difficult. Many accidents have occurred through their administration, and they may be administered in many different ways. One form of administration, however, raises no doubtful issue. During the last few years the intra-spinal administration of stovaine or cocaine and its analogues has come into use. This method of administration is still in its infancy, and medical opinion is much divided as to the part which will be played in future by this form of anæsthesia. A certain number of fatal accidents have occurred, and in many cases distressing complications have supervened, and it is not always an advantage that the patient should remain conscious during the operation. Most of the experts who gave evidence on this question incline to the opinion that this method of anæsthesia would for a long time to come be confined to a very limited class of cases where there was great risk in administering a general respirable anæsthetic. Whatever may be the future of this new method, we think that it is perfectly clear that no one except a qualified medical man should be allowed to practise it.

12. The other uses of cocaine and its analogues for operative purposes raise a debateable question. Fatal accidents have from time to time occurred in the administration of cocaine, and many individuals appear to be peculiarly susceptible to its influence. It is undoubtedly a dangerous drug, especially in unskilled and untrained hands. Some of the witnesses before us were strongly of opinion that no one except a qualified medical man or a registered dentist ought to be allowed to practise this method of anæsthesia. But the balance of opinion among the witnesses seems to be against legislative interference, and with some hesitation we acquiesce in this view. Fatal accidents have not been numerous, and many of the objections to the use of general anæsthetics have no application to local anæsthesia. No restrictions on the use of local anæsthetics (except when used intra-spinally) appear to us to be practicable or desirable. Morphia (except as an adjunct) is rarely used for surgical operations, and much more harm is done by the self-administration of morphia than by any use that is likely to be made of it for operative purposes.

13. Having considered the restrictions which we think ought to be applied to the persons who are allowed to administer anæsthetics, we think that a good deal still remains to be done before fatal accidents from this cause can be reduced to a minimum.

In the first place, the administration of anæsthetics is by no means as yet an exact science, and a perfect anæsthetic has yet to be discovered. There is no consensus of opinion as to the choice of an anæsthetic or the conditions under which it is indicated. In Scotland, for example, chloroform is more freely used than in England. Again, we have heard somewhat conflicting opinions as to the depth to which the anæsthetic should be pushed. Some witnesses were of opinion that the way of safety lay in keeping the anæsthesia light, and that the anæsthetic should be pushed only to the point of abolishing pain; while other witnesses were of opinion that the anæsthesia must be profound, otherwise the danger of surgical shock was increased. The surgeon is between the Scylla of surgical shock and the Charybdis of paralysis of the vital centres. There is need yet for much careful clinical observation, controlled, if necessary, by physiological experiments.

Secondly, we think that both practical and theoretical instruction in the use of anæsthetics should be made an obligatory portion of the medical curriculum. The General Medical Council have recommended that all medical students,

before qualifying, should be trained in the administration of anæsthetics, and all medical schools and examining bodies are, we understand, now acting on this recommendation. We think an adequate course of training in anæsthetics should be compulsory. We fully recognise the very special qualifications and capabilities which go to the making of an expert anæsthetist. It is only by long experience, coupled with special aptitude, that a man can attain to that position, but careful instruction can do a great deal to diminish the dangers incident to the administration of anæsthetics.

We would further urge on hospital authorities the importance of keeping up in every way the status of the anæsthetists on their staff. As more attention is given to the teaching of anæsthetics, and an increased prominence is given to the position of the anæsthetists, we think that the general practice in the administration of anæsthetics would improve.

14. It has been suggested to us that in the case of deaths under anæsthetics the inquest should be held before the coroner with a skilled assessor, either in addition to, or in substitution for, the jury. We think it would be impossible to differentiate between deaths under anæsthetics and other deaths involving difficult and delicate and scientific inquiries which the coroner has to conduct. In building accidents and mine accidents, technical and abstruse questions are often involved, and coroners have sometimes voluntarily called in the aid of an expert as assessor. This practice, perhaps, might be formally recognised by law, but we think it would be unwise to attempt to go further. If, in any classes of cases, assessors were made compulsory, there would be the greatest difficulty in getting competent men anywhere outside of a few of the great towns. A coroner's inquest must always be a more or less rough and ready inquiry. It is important that the inquiry should be commenced without delay, and terminated with reasonable expedition. In many cases expert witnesses are of more assistance than assessors, because their cross-examination elucidates points which might otherwise be overlooked.

At the same time we fully recognise the importance of scientific investigation when death occurs under an anæsthetic in hospitals, infirmaries, and similar public institutions. But such an investigation, conducted by the authorities of the institution, ought to be held under very different conditions from those necessarily attendant on an inquest where the main question is, whether any one was to blame or not. The object of the investigation is to determine the precise cause of the accident, the conditions which predisposed to it, the means which should be adopted in the future to avoid such accidents, and the circulation of the knowledge so obtained to the medical profession. In some of the larger hospitals such investigations, we understand, are now carried out, and we trust that in the future they will be held as far as possible in every case of doubt and difficulty.

15. As we have already pointed out, much yet remains to be learnt about anæsthetics and their administration, and we think that the most hopeful way of advancing knowledge would be the appointment of a small standing scientific Committee or Commission to deal with the subject.

The functions of such a Committee would be—

(*a*) To collect information from all sources, and to digest it when collected.

(*b*) To report from time to time on any advance made by the discovery of new anæsthetics, or by improved methods of administration.

(*c*) To direct chemical, toxicological, or physiological researches for the purpose of testing new discoveries or elucidating doubtful points.

(*d*) To make their information available to the medical profession in a convenient form, and at small cost.

The Committee should be nominated by the Home Office.

The Committee would require funds to prosecute its work, and we think that the Committee ought to have a grant from public funds, as progress in the science of anæsthetics is a matter which deeply concerns the public at large. Each year the death roll increases and at any moment any member of the public may have to undergo an operation which involves the use of anæsthetics. Recent benefactions have put a considerable sum of money at the disposal of the medical profession for the purpose of research work, and a portion of that money might well be devoted to researches in connexion with anæsthetics. If this could be arranged the charge on public funds would not be considerable.

16. We may sum up our more important recommendations as follows:—

(1) Every death under an anæsthetic should be reported to the coroner, who, after inquiry, should determine whether it is desirable to hold an inquest or not.

(2) In the case of every death under an anæsthetic the medical certificate of death should specify the fact, whether the anæsthetic was the actual cause of death or not.

(3) No general respirable anæsthetic should be administered by any person who is not a registered medical or dental practitioner.

(4) Registered dentists should be confined to the use of nitrous oxide gas for dental operations, and should not employ the general respirable anæsthetics of longer duration.

(5) Intraspinal anæsthesia should be practised only by registered medical practitioners.

(6) Practical and theoretical instruction in the administration of anæsthetics should be an essential part of the medical curriculum.

(7) Such instruction in the administration of nitrous oxide gas should be an essential part of the dental curriculum.

(8) In the case of any death under an anæsthetic in a hospital or other similar public institution, there should be a scientific investigation into the actual cause of death conducted by the authorities of the institution.

(9) A small standing scientific Committee on Anæsthetics should be instituted under the authority of the Home Office.

We have the honour to be, Sir,

Your obedient servants,

M. D. CHALMERS (Chairman).

ANNUAL REPORT OF THE MEDICAL OFFICER OF THE LOCAL GOVERNMENT BOARD.

II.[1]

Tuberculous Milk.

THE subject of tuberculous milk may be of such great importance in relation to tuberculosis in human beings that we shall devote the greater part of this, our final, notice to an extremely instructive paper on this matter, which is communicated by Professor Sheridan Delépine, director of the public health laboratory and professor of comparative pathology and bacteriology in the University of Manchester. Professor Delépine has devoted special attention to tubercle bacilli in milk since the year 1892, and in this connexion he has done a large amount of work for several of our large towns, especially for the city of Manchester. The experience thus gained has now been presented in a comprehensive report to the Local Government Board, and in this form it will be a useful work of reference.

Methods of Investigation.

Professor Delépine points out that although the presence of tubercle bacilli in tuberculous products may be ascertained by microscopical examination, by cultivation, or by inoculation, his researches have satisfied him that the first and the last of such methods are the only two which can be relied upon. As regards the microscopical examination, he thinks that, although it cannot be trusted in the case of mixed milk, it is nevertheless capable with certain precautions of yielding useful results in the case of the unmixed milk of single cows, and he furnishes some useful examples of failure in the case of mixed milk and success in the case of unmixed milks. Dealing with inoculation experiments, it was found that the subcutaneous

[1] No. I. was published in THE LANCET of April 9th, 1910, p. 1020.

inoculation of guinea-pigs on the inner aspect of the hind leg at the level of the knee, even with a small number of bacilli, produced very typical lesions, and it was shown, on a basis of some 90 preliminary experiments, that by the results it is possible to assess with a fair degree of accuracy the degree of infectiousness—for guinea-pigs—of the products employed for inoculation. With a view of establishing standards of virulence Professor Delépine subdivided the development of experimental tuberculosis into four stages, according to the number and situation of the tuberculous lesions which are visible to the naked eye at varying periods after inoculation with 1-20th of a milligramme of a pure culture of tubercle bacilli of moderate virulence, and he claims that by using animals of the same race, age, and weight, kept before and after inoculation under identical conditions, the factor of the natural resistance of the guinea-pig can be rendered almost constant. This is an interesting point. He finds that not more than 2 cubic centimetres of fluid can be safely injected into the leg of a guinea-pig, and it is his practice when testing milk for the presence of tubercle bacilli to use for each animal the sediment of 40 cubic centimetres of milk, which, as he observes, is a smaller amount than is taken by a child daily, and is about one-fifth of the weight of the experimental animal. It has been found that the oral administration to kittens of an amount of tuberculous cow's milk bearing the same relation to the body-weight was generally followed by tuberculosis, even when only a single dose was administered. Professor Delépine reminds us, however, that it does not follow that a child would be injured by the same proportional amount, although the danger of such infection is assumed, while he does not in his paper discuss the question of the communicability of bovine tuberculosis to man.

Sources of Tubercle Bacilli in Cow's Milk.

An instructive discussion on the cow's udder is contained in this paper, and there are some useful diagrams of these organs showing tuberculous affections of certain quarters. The several sources of the tubercle bacilli found in cow's milk are fully dealt with and the parts played in such production by muco-purulent discharges from the respiratory passages, by fæces, by urine, and by utero-vaginal discharges are passed in review. Professor Delépine concludes that by far the most important source of the tubercle bacilli is the cow's udder itself, and he has made some instructive investigations with the object of ascertaining how much milk might be infected by a tuberculous udder—a matter obviously of great administrative importance. It was found that one part of the tuberculous secretion could infect 100,000 parts of sound milk, and, although the dilution was carried no further, it seems not improbable that this milk diluted 1,000,000 times might still have been capable of infecting guinea-pigs. As, therefore, many cows with early tuberculous disease of the udder yield very large quantities of milk, the tuberculous milk may, when the milk of all the herd is mixed together, infect a very large quantity. Under these circumstances it is consoling to find that in the majority of cases when laboratory experiments showed that the mixed milk from a farm was capable of inducing tuberculosis, the veterinary surgeon was able to discover a cow amongst the herd with a tuberculous udder. At the same time Professor Delépine's investigations show the very great difficulty which obtains in detecting early tuberculous lesions of the udder by inspection and palpation alone, and the need for simultaneous bacteriological examination of the milk from the suspected udder is clearly demonstrated. In this part of the investigation some very useful data were secured by Professor Delépine by purchasing a cow suspected of having a tuberculous udder, and in the stable attached to his own house observing the changes which took place in the udder and the yield of tubercle bacilli in the milk.

Results of Investigations at Manchester.

A reference to some of the results which have been obtained by these many years of work in Manchester will serve to show the value, from an administrative standpoint, of investigations such as these. Of the 5320 samples of milk coming from the 12 different counties which supply Manchester 8·9 per cent. contained a sufficient number of tubercle bacilli to produce tuberculous infection. No part of the area supplying Manchester with milk appeared to be free from tuberculosis, but there were considerable differences in the cases of certain counties—i.e., from Cheshire, 9·9 per cent.; from Derbyshire, 7·5 to 12·1 per cent.; and from Staffordshire, 8·9 to 14·2 per cent. It is, however, necessary to note that these figures are not based upon the examination of equal numbers of samples in each case. But, whatever may be the real variations it is hopeful to find that, judging from the statistical data furnished, Manchester has succeeded by the use of the powers contained in the Manchester Milk Clauses in reducing the amount of tuberculous milk supplied from one of the counties which yielded the highest percentage from 16·1 per cent. in 1897–98 to 6·5 per cent. in 1907. Tuberculous lesions of the udder were found in one or more cows on at least 75 per cent. of the farms supplying tuberculous milk to Manchester, and it is probable that such udders would have been found more frequently except for the slowness of the bacteriological methods and the distance of some of the farms from Manchester.

These at present unavoidable delays enable farmers to remove tuberculous cows from their farms, and there is reason to believe that such removal actually took place in some 16 per cent. of the farms supplying tuberculous milk. It also seems, and this fact is of importance from a national point of view, that farmers who were formerly sending tuberculous milk to Manchester are now supplying the same nutriment material to other towns where there are no Manchester Milk Clauses, or at least no efficient administration of them. But Professor Delépine's investigations, if they are confirmed and accepted by other bacteriologists, appear to hold out a prospect that the delay necessary for inoculation experiments may be in some measure curtailed by improved microscopical methods, since, as we have already observed, Professor Delépine finds that by taking certain precautions it is generally possible by the microscopical method to determine rapidly whether tubercle bacilli are present or not—that is to say, in the unmixed milk obtained direct from the cow tubercle bacilli may be discovered in more than 90 per cent. of the cows yielding tuberculous milk capable of infecting guinea-pigs. The inference from this is, that a more general collection of unmixed milks is necessary in order to obtain more expeditious results. But, unfortunately, as Dr. Newsholme remarks in his introductory observations, the operations of the "Model Milk Clauses" are limited by financial considerations, and these, even in the case of a wealthy and liberal corporation such as that of Manchester, may result in the collection of only two or three samples from each of the farms supplying the city. If these Milk Clauses are to be fully effective they must go hand in hand with active sanitary administration in the district in which the milk is produced; and there can be little question that gradually those invasive powers possessed by certain large towns—amongst which is London—are stimulating the rural district councils, or at any rate the farmers, to the necessity for modernising their plant and their methods, and it would be little short of disaster were any administrative friction between the powers of the invading and invaded districts to result in curtailment of the excellent work which is being carried out.

Paratyphoid Fever.

A useful contribution to our still very imperfect knowledge of paratyphoid fever is made by Dr. William G. Savage, who furnishes a concise historical survey of this disease. The number of cases regarded as paratyphoid fever has markedly increased during recent years, and Birt, writing in 1906, referred to some 500 reported cases. Relatively few of these cases have occurred in this country, a circumstance which is generally attributed to the fact that the disease has not been sought for. Dr. Savage has recently endeavoured to obtain some idea as to the actual prevalence of the disease in England, and he has examined 200 samples of sera received from different sources. Of this number only 171 were from cases which were clinically typical of enteric fever. As a result of his investigations he found that from 3 to 3·5 per cent. of the cases of apparent enteric fever were cases of paratyphoid fever, a percentage which is in accordance with Boycott's results for this country. Attention was also directed to the prevalence of paratyphoid bacilli in human excreta, and in this connexion 53 specimens of excreta and 7 of urine were examined. But the result failed entirely to support a view that paratyphoid bacilli are natural inhabitants of the intestinal canal; they are apparently found only in cases where they have played a definite pathological rôle. Dr. Savage's further investigations suggest that epidemiologically paratyphoid fever bears no relationship either to swine fever or to outbreaks caused by meat ingestion.

THE BUREAU OF THE PERMANENT COMMISSION OF THE INTERNATIONAL CONGRESSES OF MEDICINE: MEETING AT THE HAGUE.

THE Bureau of the Permanent Commission of the International Medical Congresses, created at the Congress of Budapest, met at The Hague on March 29th and 30th.

The members of this Bureau are: Dr. F. W. Pavy for Great Britain (President), Professor Waldeyer for Germany, Dr. R. Blondel for France, Professor Müller for Hungary, and Professor Maragliano for Italy (Vice-Presidents), and Professor Wenckebach (General Secretary). Dr. J. Lucas-Championnière, as President of the International Association of the Medical Press, is also a member of the Bureau.

The agenda indicated that the Bureau would have to appoint a new general secretary, the holder of that office having resigned, and to discuss a certain number of questions relating to the definite regulations and constitution of the Commission, together with the principles that should be applied when organising future congresses, the first of these being the International Congress which is to be held in London.

The latter items of the agenda were the most important, and persons had been brought together who possess great knowledge concerning the preparation of congresses and whose counsels were likely to prove most useful. As a matter of fact, however, this part of the programme was almost entirely suppressed. It had been arranged that there should be three business sittings. The first sitting was devoted to a speech of welcome, to various formalities, to the introduction of the new general secretary, Professor Bürger, and, finally, to a long discussion raised by the Hungarian delegate, M. von Grosz. The object of this was to obtain the nomination as honorary members of Professor Wenckebach, who has resigned, and of Professor Waldeyer, who desired to resign. The rules, however, in no wise provide for the nomination of honorary members of the Commission.

Then followed a discussion on the rules of the Bureau, but it did not last long, and the settlement of the question was handed over to a subcommittee. Professor Wenckebach, the secretary, who was elected at Budapest, explained that he gave up the post because he lived at Groningen and could not attend with sufficient regularity to the labours of the Bureau which was situated at The Hague. He proposed that Professor Bürger should take his place, though this gentleman also does not live at The Hague, but at Amsterdam. The residential secretary at The Hague will be M. van den Haer. Professor Wenckebach handed to the members of the Bureau a copy of a pamphlet upon Medical Internationalism which had been prepared by Dr. P. J. Eijkman for the Association for the Promotion of International Relations (Bureau Preliminaire de la Fondation pour l'Internationalisme). At the same time it was announced that the Dutch Government proposed to give an annual subvention of 4500 florins towards the upkeep of the Bureau and its employees, and anticipated in the future the construction of a special edifice to house the institution. With a view of augmenting the resources of the Bureau it was decided that if the organising committees of the International Congresses found that there remained a balance in hand after they had settled all their accounts, a portion of this surplus should be devoted to the support of the Bureau.

A discussion as to what should be the title of the Bureau followed. Should it be called the Bureau of the Permanent Commission of the International Congresses of Medicine or the Permanent Bureau of the International Congresses of Medicine? The first title was ultimately adopted. As for the official language of the Bureau, the French language was unanimously adopted, a fact which on the morrow did not prevent the general secretary from speaking on several occasions in German.

The organisation of future congresses was then discussed, and a request to recognise Spanish as one of the official languages was rejected. Proposals to create a section of professional medicine to deal with ethical questions and points of medical practice, and to admit dentists who were not qualified medical practitioners, were likewise thrown out. In spite of the very ardent pleading of the general secretary, Dr. Blondel succeeded in securing the adoption of a motion to the effect that, generally speaking, the International Congresses of Medicine would only accept as members such persons as possessed a degree of doctor of medicine or such other diploma as conferred the legal right to practise medicine in the country where the testamur was issued.

In regard to the next congress (London, 1913) it was resolved to call the attention of the British organising committee to the fact that the majority preferred that the congress should meet during the first days of August. The German professors especially are all retained in their universities till the end of the month of July.

At the morning sitting held on March 30th the resolution of the subcommittee appointed to consider the mode of election of the Bureau and of the Permanent Commission itself was adopted. It was decided that the members of the Commission should be elected by their respective national committees for the duration of the entire period separating two international congresses. At the end of the congress, the members of each committee will hold a meeting and will elect a new delegate or reappoint their former representative. The new Commission thus created will meet at once and elect its bureau. Dr. Blondel proposed that, if possible, the president of the Bureau should be the president of the organisation preparing the next congress, or the delegate of the country where the forthcoming congress is to be held. By this means the interference of some person who was foreign to the work of the local organising committee would be avoided. This proposal was adopted.

The question of the relations between the Bureau and the International Association of the Medical Press was the subject of a long and very animated discussion. Dr. Blondel spoke on behalf of Dr. Lucas-Championnière, President of the International Association of the Medical Press, who was absent, and demanded that the communications from the permanent Bureau to the press should be made by the intermediary of the International Association of the Medical Press. Dr. Blondel urged forward the proposals formulated by the British Association of the Medical Press to the effect that the Association of the Medical Press should be entrusted with the organisation of all the relations between the press and the public. Professor Bürger and Professor Wenckebach were opposed to this proposition and declared that if it was adopted they would at once resign. Dr. Blondel in vain sought to modify his suggestion by limiting its action to such countries as possessed an association of the medical press. The General Secretary replied that he could not assume the responsibility of organisation if he was not at liberty to communicate directly to newspapers outside of the Medical Press. Dr. Blondel now sought to widen the basis of the discussion. He dwelt upon all the difficulties that would arise if the new Bureau about to be created was going to awaken justifiable mistrust. The organising committee in each country must be left to freely take what action they might deem necessary, for on these committees alone rests the responsibility of success or failure. Obviously the assistance of the press in such work is absolutely indispensable. The Bureau of The Hague should only be the depôt for the archives, the domicile of the general secretary, and the office for correspondence with the members of the Permanent Commission. But the mission of the Bureau, he thought, would prove sterile if it arrogates to itself the right to interfere with and direct the local organising committees or to restrict in any way their independence. The General Secretary doubted whether the International Association of the Medical Press was capable of taking any really effective action. Finally, Dr. Blondel's proposals were rejected.

Several other motions were brought forward. Among these was a very important report by Professor Waldeyer and Professor Posner on the manner in which the national committees were composed. Another motion was introduced by Dr. Blondel on the limitation of the subjects treated in the general reports presented to the congresses. Another proposal was made demanding that means should be organised by the Permanent Commission to consult the national committees before the final publication of the rules and regulations of the congress. Then there was the proposal made by the British Association of the Medical Press on the right the Bureau should possess of rejecting papers that were not original or of but little value.

All these proposals were set aside upon the statement that the General Secretary had not had time to study them. Professor Posner and Dr. Blondel protested that the members present, with the exception of the General Secretary, who had only been appointed the previous evening, were sufficiently experienced in regard to the organisation of congresses to take part at once in what would be a very useful discussion on matters all of which were very familiar to them. In vain it was pleaded that there was urgent need, in view of the forthcoming congress, to settle some of the points raised, and that while several competent men were gathered together good use should be made of their presence. It was pointed out that if these men had taken the trouble to come all the way to The Hague it was solely for the purpose of dealing with such questions. But under the action of the Dutch and the Hungarians all these proposals were simply handed in for the General Secretary to examine and draw up a report upon them which is to be submitted at a general meeting of the Permanent Commission. Thereupon the discussion was at once closed and, further, the sitting which had been announced for the afternoon was not held.

It is probable that the forthcoming meeting of the Permanent Commission will take place during the month of October. Dr. Blondel proposed that it should be held in London so as to be more readily able to come to an understanding with the local committee of organisation of the next International Medical Congress.

MEDICINE AND THE LAW.

Certificates of the Cause of Death and Future Legislation.

IN connexion with the subject dealt with in our recent article on the Bogey of Premature Burial[1] we have received a letter from a clergyman who points out that the unfounded rumours as to persons being buried alive might be prevented if medical practitioners were only to give certificates for the purpose of death registration after having examined the dead body. The suggestion is by no means a new one but the situation at present is as follows. The medical certificate given for the purpose of death registration in obedience to the law is not, as our correspondent seems to think, an attestation on the part of the medical man who signs it of the fact, but of the cause, of death. The recent Departmental Committee appointed to inquire into the law relating to coroners and coroners' inquests incidentally inquired into these two questions of premature burial and of certification of death so far as they might be deemed to come within the terms of its reference. On the first point the committee had before it evidence of the strongest character from Mr. A. J. Pepper to the effect that the popular scare with regard to premature burial is absolutely baseless. On the second it observes in its report that the general question of death certification is outside the terms of its reference, but proceeds to recommend in connexion with the law of coroners that a certificate should not be accepted from a medical practitioner unless it states that he has satisfied himself of the fact of death by personal inspection of the body. This recommendation it makes relevant to the subject of this inquiry by proceeding to advise that every death as to which a medical certificate such as it recommends is not given should be reported to the coroner. It will thus be seen that whenever the law is amended with regard either to coroners or to death registration the certification of the fact of death by a medical practitioner who has seen the dead body will in all probability be made compulsory. The certificates now given are regulated by an Act of Parliament passed in 1874, and are lawfully, if undesirably, given without inspection.

The Preservation of Dead Bodies with a View to Identification.

At a recent inquest held by Dr. F. J. Waldo as coroner for the borough of Southwark, it was stated that the body, that of a man found dying in the street from acute alcoholic poisoning, had not been identified. A description had been given by the police, and the jury was informed that this for the purpose of the identification of human remains was usually found to be more effective than photographs. At the same time, attention was called to the desirability of means being provided for the preservation from decomposition of the body itself in order to secure as far as possible satisfactory evidence with regard to it. At the conclusion of the inquest the jury in a rider to their verdict expressed the opinion that the London County Council should provide an apparatus by which unidentified bodies might be preserved either chemically or by refrigeration. In this connexion we note that Dr. Waldo in his annual report to the Common Council upon the work performed by him as coroner for the City of London speaks of the recent successful installation there of a Herscher's apparatus for the preservation of bodies by formalin, and informs the Common Council that it has already proved of service in ensuring identification. The first body for which it was used, that of a man found drowned, remained in it for four months, and at the end of that time was free from appreciable signs of decomposition and easily recognisable. This apparatus, installed by the Common Council, is, we believe, at present the only one in use in connexion with a coroner's court, although Section 93 of the Public Health (London) Act, 1891, enables the London County Council "to provide and fit up one or two suitable buildings" for the purpose in question. The Common Council of the City of London is to be congratulated upon having been a pioneer in this matter, and it is to be hoped that the London County Council may see its way before long to follow the example set. It expressed itself as unable to make any provision of the kind indicated as recently as January, 1909, but possibly when the results secured in the City are established it will be willing to reconsider its decision. The usefulness of an apparatus for the preservation of unidentified remains would be most readily tested in a waterside district, such as Southwark, owing, not only to the condition of bodies "found drowned," but also to the part which the river plays in crimes of violence, in suicides, and in accidental deaths.

[1] THE LANCET, March 19th, p. 803.

Looking Back.

FROM

THE LANCET, *SATURDAY*, April 14th, 1832.

THE CHOLERA IN PARIS.

SINCE the publication of the last number of our journal, the capital of France has been the scene of such melancholy events as will form one of the most gloomy pages in the history of pestilential diseases. Within ten days from its announcement in Paris, 7,000 cases of cholera have occurred, of which number 3,600 have terminated fatally. The mails received as we write, give the last *daily* report at nearly *two thousand* cases and *eight hundred* deaths within the twenty-four hours.

When it is remembered that this disease and mortality, enormous as they are, are but the amount of what has occurred in the city of Paris alone; and when it is also borne in mind that the scourge is raging with equal violence in all the *immediate suburbs* of the town, from which the cases are not reported; and, lastly, when it is taken into consideration, that at least one-third of the cases *in* Paris are not reported, as is the fact, a just idea may be formed of the overwhelming power of this almost unprecedented calamity.

If we ask ourselves,—What is the nature and what the laws which govern this anomalous pestilence?—how strange, how inexplicable are the facts we have to contemplate! In Paris, not five days before the onset of the disorder, M. VILLERME, the well known and gifted statist, in a memoir on epidemics, read before the *Academie de Medecine*, congratulated his fellow citizens on the probable, nay almost certain immunity, they were to enjoy from the cholera, as well as from all other similar visitations. "Paris," he said, "exceeded all other cities in the extent of its civilization; the inhabitants of that capital were the strongest in moral courage of any nation in the world,—were unrivalled in physical energy;" it was superintended and controlled by an excellent and indefatigable medical police; no nuisances there existed; knackeries, laystalls, dunghills, and all other similar nuisances, were carefully removed from it beyond the barriers; in short, the provisions of the "code sanitaire," taken along with the circumstances of the citizens, were either to defend them

altogether from the cholera, or so to divest the disease of its sting, that the monster would be harmless in the precincts of the privileged town, and might be visited and stared at as one of the lions of the day. But what has proved to be the fact? From the prime minister, the peer, the deputy, and the general, to the pauper, "*chiffonier*" and "*debardeur*," all classes of inhabitants have been smitten, and in equal ratio to the proportion which they bear in numbers to each other. The timid and the brave, the weakly and the robust, from the infant to the decrepid man, all suffer from the scourge; and more victims fall daily within the walls of Paris than sufficed for the overthrow of the moral pest exterminated in face of the barricades of July.

Public Health.

ANNUAL REPORTS OF MEDICAL OFFICERS OF HEALTH.

County Borough of Hanley.—The population of this borough is estimated by Mr. John Clare at 68,831, the density of the population being 35·5 persons per acre. The extent to which the services of women are being utilised for public health work at the present time is well illustrated by the fact that in Hanley alone a female health visitor and a female inspector of midwives have recently been appointed, as well as a lady doctor as school medical officer at a salary of £250 per annum. There was an epidemic of measles in Hanley during the autumn of 1909. This disease is notifiable in a voluntary sense in the district, but only as regards the first case in each household. Even with the above limitations there were no fewer than 647 cases notified during 1909. The invaded houses were visited by the sanitary inspector and instructions given as to the isolation of the patients. No child was admitted to school from an invaded house until a month after the commencement of the illness—presumably of the last case in any given house. Disinfecuion was carried out by means of formalin. In addition to all these precautions the infants' schools were closed for about two months. No comments are offered by the medical officer of health as to the value of the voluntary notification of measles, and as we are not told for how many years notification has been in force it is difficult to draw any reliable inferences from the figures furnished in this report. The fatality-rate per 100 notified cases (not, of course, all the cases which occurred) was 8 in 1909, and the same rate has varied from 4·3 to 16·1 since 1892, the rate in 1908, when there were 187 cases, having been 11 per 100 notified cases. There were 267 cases of diphtheria notified in 1909, and among the precautions taken to control the spread of the disease was the use of diphtheria antitoxin as a prophylactic, the general practitioners of the town being paid 2*s.* 6*d.* for the first person injected and 1*s.* for every other person in the same house. It is not clear whether these fees were in addition to the supply of antitoxin gratuitously. Here, at any rate, we have the municipality adopting very much the attitude as regards the prevention of diphtheria which the State adopts as regards the prevention of small-pox, and it is worthy of note that in the case of diphtheria the municipality sometimes pays not only for the prevention but also for the treatment of the disease. An extension of this principle would carry the medical practitioner into the position of becoming almost the servant of the borough council, a position which stimulates a number of instructive reflections. There were 86 cases of enteric fever notified in 1909, and it is, unfortunately, by no means clear what they were due to, as milk, shell-fish, and celery appear to have been excluded. It is not satisfactory to find so large a number of cases of enteric fever unaccounted for. On Oct. 5th, 1909, the notification of ophthalmia neonatorum was introduced, and up to the end of the year 3 cases were notified. There were 67 cases of pulmonary tuberculosis notified under the Public Health (Tuberculosis) Regulations.

Woodford Urban District.—The infantile mortality in this district showed a marked reduction on that of recent years, the rate for 1909 having been only 59·4 per 1000 births, as against an average for the last ten years of 113. The type of scarlet fever which is prevailing in the district is a very mild one, and Mr. W. G. Groves reports that several cases were not discovered until the patients were found to be desquamating. He adds that since scarlet fever became notifiable there have been in Woodford 999 cases notified with only 11 deaths, a fatality rate which suggests to some minds that possibly our isolation hospitals might be put to more profitable uses than the isolation of cases of scarlet fever. But this raises the difficult question as to how far this diminished fatality rate in the case of scarlet fever is due to the influence of isolation hospitals.

Reigate Rural District.—Dr. A. E. Porter refers in his current report to the influence of "holiday children" in introducing disease into this district, and he adds that scarcely a year passes without cases of diphtheria or scarlet fever being introduced from London or other large cities. In August there were 6 cases of diphtheria in the hospital, 5 of whom were either visitors or their victims, and he evidently suspects that these holiday children were responsible for outbreaks of scarlet fever in other parts of the district. It is proposed to distribute circulars to cottagers who take in these holiday children warning them of the danger incurred. It would seem not unreasonable to require a certificate of health with the children. Four cases of pulmonary tuberculosis were notified under the Public Health (Tuberculosis) Regulations.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In 77 of the largest English towns 8804 births and 4857 deaths were registered during the week ending April 9th. The annual rate of mortality in these towns, which had been equal to 13·5, 13·9, and 14·4 per 1000 in the three preceding weeks, further rose to 14·9 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these towns did not exceed 15·0 per 1000, and was 3·0 below the average rate in these towns in the four preceding corresponding quarters; in London the mean rate during last quarter was only equal to 14·9 per 1000. The lowest reported annual rates of mortality in the 77 towns during last week were 4·2 in Hornsey, 6·2 in Reading, 7·8 in Southampton, and 9·2 in Walthamstow; the rates in the other towns ranged upwards, however, to 19·8 in Huddersfield, 21·2 in Rotherham, 21·3 in Oldham, and 22·9 in Rhondda. In London the recorded death-rate last week did not exceed 14·7 per 1000. The 4857 deaths registered in the 77 towns during the week showed a further increase of 243 upon the numbers returned in the three preceding weeks, and included 362 which were referred to the principal epidemic diseases, against 317 and 332 in the two previous weeks; of these 362 deaths, 151 resulted from whooping-cough, 104 from measles, 35 from diphtheria, 27 from diarrhœa, 26 from scarlet fever, 17 from enteric fever, and 2 from small-pox. The mean annual rate of mortality in the 77 towns during the week from these epidemic diseases was equal to 1·1 per 1000, against 1·0 in each of the three preceding weeks. No death from any of these epidemic diseases was registered last week in Middlesbrough, Walsall, Northampton, St. Helens, or in eight other smaller towns; the annual death-rates therefrom ranged upwards, however, to 2·3 in Hastings and in Rhondda, 2·5 in Oldham, 3·1 in Liverpool, and 3·3 in Merthyr Tydfil. The fatal cases of whooping-cough, which had been 134 and 139 in the two previous weeks, further rose to 151 in the week under notice, and caused annual death-rates equal to 1·5 in Hastings, 1·7 in Birkenhead, 1·8 in Devonport and in King's Norton, and 2·2 in Oldham. The deaths from measles, which had been 78 and 93 in the two previous weeks, further rose to 104 last week; the highest death-rates from this disease during the week were 1·3 in Cardiff, 1·5 in Bootle and in Burnley, and 2·0 in Merthyr Tydfil. The 35 deaths referred to diphtheria corresponded with the number in the previous week, and included 11 in London and its suburban districts, 4 in Manchester and Salford, 4 in Leeds, and 2 both in Sheffield and in Cardiff. The 27 deaths attributed to diarrhœa showed a decline of 3 from the number in the previous week. The fatal cases of scarlet fever, which had declined in the four preceding weeks from 34 to 25, were last week 26, of which 3 occurred in Liverpool and 2 each in Stoke-on-Trent, Newport (Mon.), Rhondda, and Merthyr Tydfil. The 17 deaths referred to enteric fever showed an increase of 7 upon the low

number in the previous week; they included 3 in Liverpool and in Manchester and Salford, and 2 in London and in Nottingham. The 2 fatal cases of small-pox occurred in Blackburn and in Sheffield The number of scarlet fever patients under treatment in the Metropolitan Asylums and in the London Fever Hospital, which had steadily declined in the 25 preceding weeks from 2819 to 1611, had further fallen to 1554 on April 9th; 166 new cases of this disease were admitted to these hospitals during last week, against 180, 173, and 158 in the three preceding weeks. The Metropolitan Asylums Hospitals contained no case of small-pox on April 9th. Of the 1377 deaths registered in London during the week under notice 281 were referred to pneumonia and other diseases of the respiratory system, showing a decline of 29 from the number in the previous week, and were 70 below the corrected average number in the corresponding week of the five years 1905–09. The causes of 45, or 0·9 per cent., of the deaths registered in the 77 towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death registered during the week were duly certified in London, Bristol, Bradford, West Ham, Newcastle-on-Tyne, Hull, and in 46 other smaller towns; the 45 uncertified causes of death in the 77 towns included 8 in Birmingham, 4 in Liverpool, and 3 both in Stoke-on-Trent and in Manchester.

HEALTH OF SCOTCH TOWNS.

In eight of the principal Scotch towns 978 births and 659 deaths were registered during the week ending April 9th. The annual rate of mortality in these towns, which had been equal to 15·3 and 18·1 per 1000 in the two preceding weeks, further rose slightly to 18·2 in the week under notice. During the 13 weeks of last quarter the annual death-rate in these towns averaged 17·5 per 1000, and exceeded by 2·5 the mean rate during the same period in the largest English towns. The annual death-rates during last week in these eight Scotch towns ranged from 11·8 and 14·5 in Aberdeen and Edinburgh to 29·1 in Greenock and 29·4 in Dundee. The 659 deaths from all causes in the eight towns during the week showed an increase of but 3 upon the number in the previous week, but included 123 which were referred to the principal epidemic diseases, against 72, 77, and 82 in the three preceding weeks. These 123 deaths were equal to an annual rate of 3·4 per 1000; the mean death-rate from the same diseases in the 77 English towns last week did not exceed 1·1 per 1000. These 123 deaths in the Scotch towns included 74 from measles, 17 from diarrhœa, 14 from diphtheria, 10 from scarlet fever, 6 from whooping-cough, and 2 from "fever," but not one from small-pox. The fatal cases of measles, which had been 45 and 43 in the two preceding weeks, rose to 74 last week and exceeded the number in any previous week of this year; they included 28 in Dundee, 15 in Glasgow, 14 in Greenock, 11 in Edinburgh, and 6 in Leith. The 17 deaths attributed to diarrhœa showed a decline from the high number in the previous week, but included 11 in Glasgow and 5 in Dundee. The 14 deaths referred to diphtheria considerably exceeded the numbers in recent weeks; 6 occurred in Glasgow, 3 in Greenock, and 2 both in Edinburgh and in Paisley. The fatal cases of scarlet fever also showed a marked increase, and included 6 in Glasgow and 2 in Dundee. Two deaths from whooping-cough were returned in Glasgow, in Edinburgh and in Dundee. Of the 2 deaths referred to "fever" 1 case of typhus was registered in Glasgow and 1 of enteric in Paisley. The deaths in the eight towns referred to diseases of the respiratory system, which had been 100 and 122 in the two previous weeks, declined again to 114 in the week under notice, but exceeded by 6 the number in the corresponding week of last year. The causes of 17, or 2·6 per cent., of the deaths in the eight towns were not certified or not stated; in the 77 English towns the proportion of uncertified causes of death did not exceed 0·9 per cent.

HEALTH OF IRISH TOWNS.

In Dublin 255 births and 181 deaths were registered during the week ending April 9th. The 181 deaths exceeded the numbers in recent weeks, and were equal to an annual rate of 23·4 per 1000; the rate during the same week did not exceed 14·7 in London and 14·5 in Edinburgh. During the 13 weeks of last quarter the annual death-rate in Dublin averaged 23·8 per 1000, against 14·9 in London. The 181 deaths registered in Dublin during the week under notice included but 6 which were referred to the principal epidemic diseases, against 6 and 2 in the two preceding weeks; of these 6 deaths, 4 resulted from diarrhœa and 1 each from diphtheria and enteric fever, whereas no death was referred to measles, scarlet fever, whooping-cough, or small-pox. The death-rate during the week from these principal epidemic diseases did not exceed 0·8 per 1000 in Dublin last week, the rate from the same diseases last week being 1·1 in London and 2·5 in Edinburgh. Of the 181 deaths registered in Dublin last week, 71, or 39·2 per cent., were recorded in public institutions. The causes of 9, or 4·9 per cent., of the deaths in the city last week were not certified. In Belfast 254 births and 168 deaths were registered during the week under notice. The annual rate of mortality in Belfast, which had been equal to 16·7 and 18·4 per 1000 in the two preceding weeks, further rose to 22·4 in the week ending April 9th, and was only slightly below the high rate in Dublin. During the 13 weeks of last quarter the annual death-rate in Belfast averaged 20·3 per 1000, against 23·8 in Dublin. The 168 deaths in Belfast during the week under notice included 24 which were referred to the principal epidemic diseases, against 14 and 17 in the two preceding weeks; of these 24 deaths 12 resulted from whooping-cough, 11 from measles, and 1 from diphtheria, but not one from scarlet fever, enteric fever, diarrhœa, or small-pox. These 24 deaths were equal to an annual rate of 3·2 per 1000, whereas the rate from the same diseases did not exceed 0·8 in Dublin. The fatal cases both of whooping-cough and of measles showed a considerable increase in Belfast last week. The causes of all but one of the 168 deaths in Belfast last week were duly certified.

VITAL STATISTICS OF LONDON DURING MARCH, 1910.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan boroughs. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to an annual rate of 4·1 per 1000 of the population, estimated at 4,872,702 persons in the middle of the year. In the three preceding months the rates had been 5·4, 4·5, and 4·6 per 1000 respectively. The lowest rates last month were recorded in Kensington, Chelsea, Hammersmith, Stoke Newington, Holborn, and the City of London; and the highest rates in Fulham, Poplar, Bermondsey, Battersea, Deptford, Lewisham, and Woolwich. The prevalence of scarlet fever showed a slight decrease last month; among the several boroughs this disease was proportionally most prevalent in St. Pancras, Lambeth, Battersea, Wandsworth, Lewisham, and Woolwich. The Metropolitan Asylums Hospitals contained 1584 scarlet fever patients at the end of last month, against 2392, 1962, and 1740 at the end of the three preceding months; the weekly admissions averaged 180, against 250, 198, and 204 in the three preceding months. Diphtheria was considerably less prevalent than it had been in any of the six preceding months; the greatest proportional prevalence of this disease was recorded in Fulham, Stepney, Poplar, Bermondsey, Battersea, Deptford, Greenwich, Lewisham, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 904, 883, and 908 at the end of the three preceding months, had declined to 852 at the end of last month; the weekly admissions averaged 82, against 97, 96, and 93 in the three preceding months. The prevalence of enteric fever showed but little variation from that recorded in the previous month; this disease was proportionally most prevalent in Kensington, Chelsea, the City of Westminster, Finsbury, Poplar, Battersea, Camberwell, and Greenwich. There were 84 enteric fever patients under treatment in the Metropolitan Asylums Hospitals at the end of last month, against 62 and 75 at the end of the two preceding months; the weekly admissions averaged 12, against 10 and 12 in the two preceding months. Erysipelas was proportionally most

* Including membranous croup.

† The death-rates are corrected for variations in sex- and age-constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

prevalent in Hammersmith, Fulham, Finsbury, Shoreditch, Bethnal Green, Southwark, Battersea, and Deptford. The 21 cases of puerperal fever notified during the month included 2 in Hammersmith, 2 in Fulham, 2 in Hackney, 2 in Poplar, 2 in Wandsworth, and 2 in Lewisham. Of the 17 cases of cerebro-spinal meningitis 3 belonged to Islington and 2 each to St. Pancras and Stepney.

The mortality statistics in the table relate to the deaths of persons actually belonging to the various boroughs, the deaths occurring in institutions having been distributed among the several boroughs in which the deceased persons had previously resided; the death-rates are further corrected for variations in the sex and age constitution of the population of the several boroughs. During the five weeks ending April 2nd, the deaths of 6171 London residents were registered, equal to a corrected annual death-rate of 13·9 per 1000; in the three preceding months the rates were 15·8, 14·8, and 16·6 per 1000. The lowest death-rates last month were 9·8 in Hampstead, 10·1 in Fulham, 11·4 in Wandsworth, 11·8 in Woolwich, and 12·1 in Lewisham; the highest rates were 15·3 in St. Marylebone, 16·0 in Holborn, 16·1 in Finsbury, 17·1 in Shoreditch, 17·2 in Bethnal Green, 17·5 in Bermondsey, and 18·0 in Southwark. The 6171 deaths from all causes included 487 which were referred to the principal epidemic diseases; of these 122 resulted from measles, 33 from scarlet fever, 38 from diphtheria, 227 from whooping-cough, 18 from enteric fever, 1 from ill-defined pyrexia, and 48 from diarrhœa, but not any from small-pox or from typhus fever. No death from any of these epidemic diseases was recorded last month in the City of London; among the metropolitan boroughs they caused the lowest death-rates in Chelsea, the City of Westminster, Hampstead, Stoke Newington, and Lambeth; and the highest rates in St. Marylebone, Shoreditch, Bethnal Green, Poplar, Deptford, and Greenwich. The 122 deaths from measles were less than half the corrected average number in the corresponding period of the five preceding years; the greatest proportional mortality from this disease was recorded last month in Paddington, Hammersmith, Shoreditch, Bethnal Green, and Deptford. The 33 fatal cases of scarlet fever were 15 fewer than the corrected average number; this disease was proportionally most fatal in St. Marylebone, Bermondsey, Wandsworth, Deptford, and Woolwich. The 38 deaths from diphtheria showed a decline of 40 from the corrected average number; the greatest proportional mortality from this disease occurred in Finsbury, Stepney, Bermondsey, and Bethnal Green. The 227 fatal cases of whooping-cough were 26 in excess of the corrected average number; the highest death-rates last month from this disease were recorded in St. Marylebone, Islington, Shoreditch, Stepney, Poplar, Deptford, and Greenwich. The 18 deaths referred to enteric fever were equal to the corrected average number; of these 18 deaths 3 belonged to Kensington, 3 to Lambeth, and 2 each to Paddington, Stepney, and Poplar. The 48 fatal cases of diarrhœa were 19 below the corrected average number; the greatest proportional mortality from this disease was recorded last month in St. Marylebone, Holborn, Finsbury, Poplar, and Battersea. In conclusion, it may be stated that the aggregate mortality in London last month from these principal infectious diseases was nearly 30 per cent. below the average.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

IN accordance with the provisions of Her late Majesty's Order in Council of April 1st, 1881, Surgeon Henry William Worth Townsend has been allowed to withdraw from His Majesty's Naval Service, with a gratuity (dated April 6th, 1910).

ROYAL ARMY MEDICAL CORPS.

Colonel Sir David Bruce, C.B., F.R.S., has arrived home from Uganda on completion of a tour of special duty connected with the Sleeping Sickness Commission. Lieutenant-Colonel M. O'D. Braddell has been selected for increased pay under Article 317 of the Royal Warrant from March 6th, vice Lieutenant-Colonel W. G. Macpherson, C.M.G., promoted Colonel. Lieutenant-Colonel J. V. Salvage has been appointed to command the station hospital at Muttra. Lieutenant-Colonel C. H. Burtchaell, Staff Officer to the Principal Medical Officer, Irish Command, has been directed to join the London District for temporary duty. Lieutenant-Colonel H. Cocks, from Wellington, Lieutenant-Colonel F. G. W. Gordon-Hall, from Muttra, and Lieutenant-Colonel H. P. G. Elkington, from Jhansi, have arrived home on expiration of their tour of service in India. Lieutenant-Colonel C. L. Josling, recruiting medical officer, London Recruiting Area, has been transferred to the Western Command. Lieutenant-Colonel R. W. Wright has been transferred from the Royal Arsenal to the Eastern Command. Lieutenant-Colonel G. Wilson, from Multan, has been posted to the Eastern Command and appointed in charge of the Military Hospital at Dover. Lieutenant-Colonel W. T. Swan, from Chakrata, has been appointed to the Royal Victoria Hospital at Netley and placed in charge of the Medical Division. Major H. G. Martin has been transferred from the Seventh (Meerut) Division to the Eighth (Lucknow) Division and appointed to command the station hospital at Lebong. Major J. Thomson has been posted to Pretoria and Major O. L. Robinson to Meerut. Major H. E. Winter has been transferred from Chatham to Gravesend and Major A. Pearse from Woolwich has been posted to Chatham. Major W. P. Gwynn, from Quetta, has been posted to Karachi. Major K. M. Cameron has been appointed specialist in advanced operative surgery to the Aldershot Command. Major S. A. Archer has been appointed specialist in ophthalmology to the Third (Lahore) Division, with effect from Feb. 1st. Major W. E. Hudleston, from Mhow, has been posted to Gosport, and Major H. O. B. Browne-Mason, from London, has been posted to Poona. Captain T. S. Blackwell has been granted an extension of his leave from India. Captain E. T. Inkson, V.C., has been appointed specialist in dermatology to the Ninth (Secunderabad) Division, with effect from March 1st. Captain S. O. Hall, Captain A. J. Hull, Captain D. P. Watson, and Captain R. T. Collins have arrived home on completion of a tour of service in India. Captain J. W. Leake and Captain A. L. A. Webb have embarked for West Africa. Captain F. M. M. Ommanney and Captain A. C. Osburn have been posted for duty to the Eastern Command. Captain J. H. R. Bond, from York, has been appointed to Mhow. Captain R. N. Woodley, from Cork, has been transferred to Cahir, and Captain J. A. W. Webster, from Gravesend, has been transferred to Shoeburyness. Captain T. E. Fielding has been appointed Adjutant of the Royal Army Medical Corps School of Instruction, Territorial Force, London District. Lieutenant M. J. Williamson, from Tidworth, has been posted for duty to Bulford Camp, Salisbury Plain. Lieutenant D. F. Mackenzie, from Lebong, has been posted to Calcutta. Lieutenant G. F. Dawson has been attached for special duty connected with antityphoid inoculation to the King's Royal Rifles stationed at Meerut. Lieutenant J. E. Ellcome and Lieutenant R. M. Dickson have embarked for India.

Captain Albert J. W. Wells retires, receiving a gratuity (dated April 13th, 1910).

Lieutenant Francis L. Bradish to be Captain (dated Jan. 30th, 1910).

INDIAN MEDICAL SERVICE.

The Chancellor of the Allahabad University has nominated Lieutenant-Colonel C. C. Manifold, Officiating Inspector-General of Civil Hospitals in the United Provinces, to be a Fellow of the Allahabad University. Lieutenant-Colonel H. B. Melville, Civil Surgeon of Simla (West), has been appointed to officiate as Health Officer and District Plague Medical Officer during the absence on leave of Captain K. W. Mackenzie. Lieutenant-Colonel F. J. Crawford, Civil Surgeon, Hooghly, has been granted two years' leave. The Viceroy has selected Major F. O'Kinealy for the appointment of Civil Surgeon at Simla in succession to Captain J. Leicester, who has been appointed to officiate as Professor of Midwifery at the Medical College, Calcutta, during the absence on leave of Lieutenant-Colonel C. R. M. Green. Major F. D. S. Fayrer, Bombay, has had his leave from India extended by four months, on medical certificate. Major W. H. Ogilvie has had his leave extended. Captain J. K. S. Fleming has been appointed to officiate as Civil Surgeon at Banda, vice Captain W. MacM. Pearson, granted leave. The services of Captain G. P. T. Groube, Assistant Plague Medical Officer, Ferozepore, have been placed at the disposal

of the Home Department of the Government of India. Captain T. S. Ross from Madras General Hospital has proceeded to Amritsar for special duty in connexion with malaria field-work under the direction of Captain S. R. Christophers, assistant to the Director of the Central Research Institute, Kasauli. Captain J. Husband, medical officer of the 59th Scinde Rifles (Frontier Force), has been appointed to the charge of the Brigade Laboratory at Kohat. Captain C. A. Godson has been appointed to the charge of the jail at Barisal, Eastern Bengal, vice Captain L. B. Scott. Captain W. H. Tucker has been granted leave for one year and seven months, with effect from April 9th, and Captain J. H. Burgess has been granted one year's furlough combined with study-leave. Captain W. D. Richie, Captain W. H. Dickinson, Captain H. Dalk, and Captain H. B. Drake have arrived home on leave. Lieutenant F. O'D. Fawcett, attached to the 23rd Cavalry (Frontier Force) at Kohat, has been transferred for duty with the 59th Scinde Rifles (Frontier Force) at Peshawar. Lieutenant A. J. H. Russell has been appointed a specialist in the prevention of disease at Secunderabad.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Charles Max Page to be Lieutenant (on probation) (dated March 14th, 1910).

THE TERRITORIAL MEDICAL SERVICE.

At a meeting of the General Purposes Committee held recently at Warwick, it was stated that the British Medical Association brought to notice that it considered that officers commanding general hospitals should have seats on the county associations and that it thought it desirable that means should be found whereby each medical unit should have its own drill hall. Sir Henry Fairfax Lucy stated that some time ago the War Office allowed them to increase their number but would go no further, and he did not see what could be done in the matter. The principal medical officer of the division had approved of the suggestion of the British Medical Association, but in view of the chairman's statement it was felt that no steps could be taken.

The London Royal Army Medical Corps School of Instruction for Territorial R.A.M.C. officers announces that a course of drill for all London medical units will be held at Somerset House during April, May, and June, on Tuesday and Friday evenings, commencing on April 19th. A revision class for officers for the May examinations in subject B will be held at Calthorpe-street, W.C., on Tuesdays, May 3rd and 10th; Thursdays, May 5th and 12th; and Fridays, May 6th and 13th.

THE BRITISH RED CROSS SOCIETY.

Sir Frederick Treves will address a meeting convened by the Hon. Mrs. Charles White, Vice-President of the Aldershot and Farnborough Division of the Red Cross Society, at the Masonic Temple, Station-road, Aldershot, to-day (Friday), April 15th, at 2.45 P.M.

The annual meeting of the Gloucestershire branch of the Red Cross Society was held at the Shire Hall, Gloucester, on April 9th, under the presidency of the Duchess of Beaufort. The report showed an available balance of £75. Captain Colchester Wemyss, the honorary county director, said 15 men's detachments and something like 35 or 36 women's detachments had been either definitely raised or were in process of formation. By June 1st, when they had to send in their first half-yearly returns to the War Office, he had no doubt they would be able to send in a list of no less than 50 detachments (including men and women) definitely formed and in proper working order.

EXPERIENCES WITH BIER'S METHOD IN THE GERMAN NAVY.

During the years 1906–07 it is reported (Sanitätsbericht über die K. Deutschen Marine) that Bier's method was used in the German Navy for the treatment of whitlows and boils. Whitlows, it is said, were (as in other countries) sometimes cured easily, but in certain cases required extensive and repeated incisions and scrapings with prolonged attention. Of the 252 cases, however, that occurred, some 60 were treated by Bier's plan of venous congestion with great advantage, and the sooner this was commenced the better was the result. It was particularly noted that severe advancing inflammations began at once to decrease as soon as the elastic bandage was applied. Ordinary methods of treatment were employed at the same time, but much smaller incisions were required. Connective-tissue inflammations and abscesses occurred so frequently in men going barefoot that the men of one training ship had to be made to wear boots always. It would be interesting to learn whether the decks of this ship were washed with perchloride of mercury as is done in some English mail steamers, for such a precaution materially prevents accidental wounds from becoming inflamed. Bier's method was also used in the treatment of these abscesses, and is commended by all who write with experience of its use, and by some enthusiastically. The only case of abscess invalided was treated exclusively on the old lines. Boils occurred mostly in summer and in the tropics, and particularly on the knees and elbows of men working in boilers. Bier's suction glasses were used constantly. They greatly diminished pain and subsequent disfigurement. But the editor of this section (Marine Stabsarzt Dr. Tillmann) strongly recommends the puncture of boils and threatening boils with a fine electric cautery as less painful, more convenient, and necessitating a shorter after-treatment than any other method of treatment.

THE NAVAL MEDICAL SUPPLEMENTAL FUND.

At the quarterly meeting of the directors of the Naval Medical Supplemental Fund, held on April 12th, Inspector-General W. H. Lloyd, R N., in the chair, the sum of £60 was distributed among the several applicants.

Surgeon-General John C. Dorman, C.M.G., has been appointed an Honorary Physician to the King, vice Surgeon-General Sir A. Keogh, K.C.B.

Correspondence.

"Audi alteram partem."

THE CLIMATE OF HONG-KONG, WITH ACCOUNT OF JOURNEY FROM THERE TO LONDON.

To the Editor of THE LANCET.

SIR,—Reverting to your article in THE LANCET of Jan. 15th on "December, 1909, at Home and Abroad," p. 188, I would refer to the climatic conditions prevailing in Hong-Kong during the past winter months. In no other part of the world that I know of was there so much sunshine. In the three months, November to January inclusive, there were 577·9 hours of sunshine; in December alone there were 249·7 hours, 61 per cent. of the greatest possible duration of sunshine. The rainfall was practically *nil*, amounting to less than an inch for the three months, and the air is cool and bracing, the prevailing wind being E.N.E. I am convinced that were the facts known this place would be used more as a winter resort for Britishers who can afford to travel and wish to escape the inclement wintry weather in England. Once the Kouloon-Canton railway is completed—and we hope to have trains running on the British section this year—and the Canton to Hankow railway is finished, one will be able to travel from Calais to Kouloon in a few days over a fortnight.

Only last May travelling from Hong-Kong to England *viâ* Siberia I did the journey in less than 20½ days. I left Hong-Kong on May 4th at 1.15 P.M. and travelled by the Pacific Mail Steamship Company's steamer *Siberia* (18,000 tons) to Shanghai. We arrived at Woosung early on May 7th and were in Shanghai at 10 A.M. that day. We had 36 hours there and left Shanghai at 10 P.M. on May 8th, travelling by the *Kobe Maru* to Dalny, where we arrived at 7 P.M. on May 10th. I spent the night at the Yumato Hotel and left Dalny at 11.15 A.M. on May 11th. Thence we journeyed to Changchun by the Southern Manchurian Railway *viâ* Lao Yang (one of the battlefields of the late Russo-Japanese war) and Mukden, arriving at Changchun at daylight on May 12th. We there changed to a Russian train, as we were here on the Russo-Japanese frontier, left at 6 A.M., and arrived at Harbin at 4 P.M. This part of the journey was very uncomfortable, as the train was a badly appointed one; many of us had to be content with second-class accommodation and very inferior at that.

We had quite a rush to transfer ourselves and luggage into the "International Train de Luxe" from Vladivostock to

Moscow, which was awaiting us; several of the passengers lost articles of luggage, especially one lady, who practically lost all of hers, and we left Harbin at 4.30 P.M. on May 12th for Moscow. On the 13th we awoke quite early to find snow lying on the ground; during the night we had ascended some 4000 feet. At 10.45 A.M. we had a few minutes' wait at Khaidar; the temperature was down to 52° F. (at Shanghai it was between 80° and 90° F. on the afternoon of May 8th). We reached the frontier town between Chinese and Russian Siberia at 3 P.M. that afternoon; here we had our baggage examined by the Customs officers. We next traversed the Trans-Baikal district. May 14th: At 7 A.M. we were 3700 feet up; water frozen over here; passed through pine forests. May 15th: 3400 feet altitude at 9.30 A.M. 12 noon arrived at Khilok; very cold, snow falling. Afternoon we descended, and at 6 P.M. were at an altitude of 2100 feet, passing now through an uncultivated plateau with pine trees growing thereon. At Lake Baikal, which was partly frozen over, it was a lovely sight, the railway skirting the borders of the lake, the mountains behind being covered with snow; this with the sun shining on them, reminded one forcibly of the Swiss mountain scenery. We arrived at Irkutsk at 9.15 A.M., some 1400 feet above the sea level. We changed trains here and travelled direct to Moscow. May 16th: Quite cold again this morning; snow still lying on the ground; still traversing pine forests. Arrived at Kranoiavek 7 P.M. (500 feet altitude). After this the railway ascended to some 1500 feet altitude. May 17th: At 10.30 A.M. at Taija, the junction for Tomsk; raining during the night; weather much milder. May 18th: Omsk at 9 A.M. May 19th: Crossed the Ural Mountains last night. This day we were delayed for some few hours by having to stop and replace an overheated axle. May 20th: At breakfast we found we were some nine hours late, passing through lovely country with lilies of the valley growing wild, large bouquets of which could be bought for a trifle at the stations. May 21st: Arrived at Moscow 4 P.M., too late to catch the connexion to Warsaw. We just had time to see the Kremlin, &c., and took the night train to St. Petersburg, where we arrived at 9.30 A.M. on May 22nd. Spent 12 hours there; it was very cold, temperature below 40° F. Left St. Petersburg at 10 P.M. that night and travelled in "the Nord express" through Germany and Belgium *viâ* Ostend to Dover, reaching Charing Cross at 10 P.M. on the 24th.

I have detailed this journey somewhat, as I thought it might prove of interest to some intending travellers. Altogether the journey took me 20½ days from Hong-Kong to Charing Cross, and out of that time I had a day and a half at Shanghai, a night at Dalny, and practically a day at St. Petersburg; so that with a through railway connexion between Hong-Kong (Kouloon) and Calais the journey will soon be done in from 16 to 18 days or even less.

I attach the meteorological observations for the three months as supplied by the director of the observatory.

I am, Sir, yours faithfully,

J. M. ATKINSON,
Principal Civil Medical Officer.

Hong-Kong, Feb. 27th, 1910.

*** The official meteorological observations enclosed fully bear out Dr. Atkinson's opening remarks.—ED. L.

THE OCCURRENCE OF ADVENTITIOUS SOUNDS IN THE NORMAL CHEST.

To the Editor of THE LANCET.

SIR,—I have read with great interest the article of Dr. C. Willett Cunnington upon a Note on the Crepitations Heard in the Third Left Intercostal Space in Some Cases of Mitral Stenosis, which occurs in your issue of March 19th. The occurrence of adventitious sounds in individuals in whom there is no other evidence of respiratory trouble is a not uncommon phenomenon, and it was the subject of a short communication which I made at the Winnipeg meeting of the Canadian Medical Association last August. In many apparently healthy people medium or fine crepitations may be heard along the borders of the lungs, especially the left lung, which soon clear up upon the individual taking a few long breaths. The conclusion was come to last year that these crepitations were due to a state of partial collapse of the edges of the lungs that may exist in people who have not taken full breaths for some time. Experiments upon several cadavera seemed to support such a view, as we found that on listening along the edges of recently removed lungs, while they were being inflated, exactly the same sounds occurred as we heard during life. The fact of their rapid disappearance upon deep breathing would also support the view that they are due to collapse and not to congestion or fluid there.

I have not noted that such sounds are specially present in cases of mitral stenosis, but certainly they are not limited to such cases. Dr. Cunnington says that the sounds that he describes are limited to an area which could be covered by a halfpenny in the third left intercostal space, but in many cases they are heard over a much more extended area than this, according to our experience. Thus in a case of acute rheumatism examined this morning, in which there is a slight mitral regurgitation with no evidence of stenosis, I was able to demonstrate to my class crepitations along several inches of the anterior border of the left lung, which rapidly cleared up upon the patient taking a few long breaths. All the same, any condition that would tend to produce collapse of a portion of the lung would be apt to bring about such crepitations, and hence it would seem likely that Dr. Cunnington's explanation of the sound as being due to dilatation of the left auricle would be the correct one.

The chief importance of recognising that such crepitations may occur in normal lungs is that one is less apt to be led into a diagnosis of tuberculosis, as has occurred in one's own experience. We found these crepitations present in about one-third of all the patients in the Children's Hospital here last summer, in the majority of whom there were no other signs of anything abnormal in the lungs. When such sounds are detected in the chest it would seem rational to recommend breathing exercises.

I am, Sir, yours faithfully,

R. D. RUDOLF.

Toronto, March 30th, 1910.

SIMULTANEOUS FRACTURE OF THE PATELLÆ.

To the Editor of THE LANCET.

SIR,—When Mr. William Sheen published his interesting case of Simultaneous Fracture of the Patellæ in THE LANCET of Nov. 13th, 1909, I was struck with the rareness of the lesion. Having had occasion lately to search very thoroughly through the literature of fractures of the patella, I have kept a look-out for records of the simultaneous fracture of both bones. Besides the references which Mr. Sheen gave in his paper I have come across the following paragraph in the *Medical Times and Gazette*, 1874, Vol. II., p. 670:—

Fracture of both patellæ from muscular action.—Dr. Marcy relates the case of a strong woman, aged 38, weighing 170 or 180 pounds, who, while crossing from the curb-stone to the street, by a misstep turned the foot obliquely, and, to save herself from falling, made violent muscular exertion, and fell down. Both patellæ were found to be transversely fractured near the middle, with a separation of two inches. Ligamentous union followed, the fragments being separated from a quarter to half an inch.—*Boston Journal*, October 8.

I venture to send the reference, feeling sure that it will be of interest to Mr. Sheen and to numerous readers of THE LANCET who will have noticed his paper.

I am, Sir, yours faithfully,

A. E. JOHNSON.

Middlesex Hospital, W., April 11th, 1910.

THE SUPPLY OF ANTITETANUS SERUM IN LONDON.

To the Editor of THE LANCET.

SIR,—We have observed paragraphs in the lay papers, and also in the trade press, to the effect that a patient in one of the hospitals suffering from tetanus was unable to receive serum treatment for two days in consequence of there being no antitetanus serum to be had in London.

Please permit us to say that we had on hand at the time stated, and always have on hand, ample supplies of antitetanus serum, and medical men may be assured that all possible requirements for such can be met at a moment's notice. We are, Sir, yours faithfully,

PARKE, DAVIS, AND CO.

Beak-street, W., April 6th, 1910.

DIFFICULT POINTS IN LIFE INSURANCE.

To the Editor of THE LANCET.

SIR,—As the candidate for insurance concerned in the case which you quote in an annotation with the above heading which appeared in THE LANCET of April 2nd, I have to say that I am certain that a mistake was made in the examination of my urine. If I really believed that a temporary trace of albumin was present I should say nothing, but to believe this one has to suppose that a specimen for some extraordinary reason had only on that particular day showed this abnormality. The urine was carefully tested previous to that day and several times subsequently, on one occasion by an expert, who found it quite healthy and "*absolutely* free from any abnormal constituent." Also, it takes something to make one believe that a deeply amber coloured urine has a specific gravity of 1012. That the same medical examiner at the same examination made a mistake about my height, making me nearly two inches shorter than I am, only shows that his facts were not to be depended on.

I am, Sir, yours faithfully,

April 9th, 1910. THE ONE CONCERNED.

SOLDIERS' TEETH AND OFFICERS.

To the Editor of THE LANCET.

SIR,—I observe that the editor of the *Army and Navy Gazette*, in the issue of that paper of April 9th, pokes fun at you for suggesting that company commanders should be held responsible for the cleanliness of teeth. Well, Sir, he should know that for the exercise of this very proper supervision it is not necessary to have any "morning parade"; the soldiers' teeth could be inspected at a fatigue "fall-in" in their barrack rooms. If the officer can, and does, supervise the cleanliness of feet, it would be most useful work for him to see that the men's teeth are properly brushed. The medical officer is sufficiently well employed with the treatment of the sick and sanitary duties, and might well be helped in a routine that requires no expert medical knowledge and would be of the greatest use to his men.

The disinclination shown by officers to concern themselves with every detail of their company men's welfare should not be encouraged. I have seen on inspection in regimental kitchens boxes containing bread, butter, and cheese in contact with soiled shirts, filthy socks, and brushes and combs. I need scarcely say I did not fail to make generals aware of this state of affairs. Army medical officers cannot live in barrack-rooms every day and all day, but company and regimental officers may well expect to see that their men are cleanly, get good and wholesome food, and that that food is not subjected to contamination.

I am, Sir, yours faithfully,

April 11th, 1910. A. M. O.

A MEDICAL SURVEY IN THE PHILIPPINES.

(FROM A CORRESPONDENT.)

A MORE than ordinarily interesting and important piece of medical work recently has been accomplished in the Far East under the auspices of the Philippine Government. A comprehensive survey on similar lines would do much to unravel knotty problems which still remain unsolved in many of our tropical dependencies and would be well worth the consideration of our colonial authorities. The survey in question was undertaken by the Bureau of Science coöperating with the Bureau of Health, and an expedition was planned to make a complete study of a native town in the Philippine islands under normal conditions. Without mentioning the names of the different specialists (all of them American medical men) who took part in it, one has only to note the headings of the reports to appreciate the complete and thorough character of the survey. The town selected was Taytay in the province of Rizal, with a population of 6000 and a death-rate varying from 27·91 per 1000 to 45·42 per 1000: it had a bad record from a sanitary standpoint. The reports dealt with the following subjects: Geology and Water-supply of Taytay; Bacteriological Analysis of the Water-supply; Chemical Analysis of Taytay Waters; Principal Foods Utilised by the Natives; The Food of the People of Taytay from a Physiological Standpoint; Mosquitoes and Other Insects; Vital Statistics; General Sanitary Conditions; Animal Parasities of the Intestine; Examination of the Blood, with Special Reference to Malaria; Filariasis, Malaria, Tuberculosis, Typhoid Fever, Goitre, Beri-beri, Venereal and Skin Diseases; Disposal of Excreta; and Table of Physical Examinations.

All these interesting papers, covering in the minutest detail the work of the different branches of the survey, have been reviewed and summarised by Dr. R. P. Strong, chief of the Biological Laboratory, Bureau of Science, Philippine Islands. It was the intention during the survey not only to observe how much sickness there was present and the nature of such sickness, but to examine into the character of the population, the conditions under which the people lived, the food which they ate, the water which they drank, and the diseases to which they were liable to be exposed. Anthropometric measurements were performed, and in the case of any of the inhabitants who were found at all sick or abnormal a medical history was taken and a physical examination performed; the blood, fæces, and sputum were examined microscopically, and in many cases where the nature of the complaint warranted serum reactions, differential blood counts, and examinations of the urine were made. A dispensary was established at which all of the cases of disease thus discovered were treated free of charge. A census was also taken and in the course of this work the entire town was covered by a house-to-house inspection, the name, age, and sex of each inhabitant, together with the surrounding conditions under which he lived, being entered upon a separate card for each house. The members of the expedition were able by means of this census to locate cases of serious or interesting diseases which otherwise might not have come to their attention. In some cases a person afflicted with a disease was able to direct the members of the expedition to other persons similarly afflicted, thus assisting in the discovery of all cases of disease in the town. This was particularly true in regard to goitre and yaws diseases, which the people could recognise easily. A laboratory and a clinic were established and the plan of work was outlined as follows. To each individual who presented himself a ticket bearing his name was given. and a number, together with the name, sex, age, occupation, and residence of the individual, was placed upon a clinical record card. A separate alphabetical index of names was kept in order to avoid error if a ticket were lost. Each person was then supplied with a test tube or bottle, in which he was instructed to bring a specimen of his fæces on the following day. As many as could be examined were then passed to another room, where they were subjected to a physical examination. A hæmoglobin estimate and examination for malarial or other parasites were made of the blood. The results of the examination were entered on the clinical card, and in addition separate records were kept of all laboratory examinations. If an individual proved of any particular interest from a medical standpoint he was detained for other examination; otherwise he was discharged, or if sick was sent with his clinical card to the dispensary for treatment. The difficulties in carrying out the investigations were not so great as had been anticipated; the people throughout the town took considerable interest in the work, and there was comparatively little difficulty encountered in making the various physical and blood examinations, &c.

In relation to the entomological study of the town two new species of mosquitoes were met with, both belonging to the genus Culex. Mosquitoes of the sub-family anophelinæ (Myzomyia rossii Giles) were found breeding, particularly in the districts of the town along the banks of streams and in all bodies of stagnant water around the wells; they were most numerous along the stream running through the town. It is interesting to note that the distribution of the anophelinæ, as found by the entomologist, corresponded very well with the districts in which the cases of malaria were discovered by the clinicians. An examination of the fæces of 1000 persons in the town showed that 95 per cent. of the people were infected with some form of intestinal worm. In Manila it has been found that Filipinos are almost universally infected with these worms. An attempt to discover any localisation in groups of the cases infected with ascaris, hookworms,

trichuris, strongyloides, oxyuris, or amœba in any part of the town of Taytay in proximity to any wells or streams by families or occupations gave negative results. Only 11·6 per cent. of those examined were found to harbour hookworms, 82 per cent. had ascaris, and about 77 per cent. trichuris. About 1 per cent. were found to be infected with tuberculosis; 1 per cent. had goitre. Only a very small amount of venereal disease was observed, while, on the other hand, yaws was fairly prevalent, 1 per cent. of the children being infected. Epidemics of cholera, typhoid fever, and bacillary dysentery occur from time to time. Only about 2 or 3 per cent. of those examined in Taytay were found to be harbouring the malarial parasite, but this is not surprising, since the investigations were carried on in the midst of the dry season, when malaria is at a minimum. Mosquito nets were used practically not at all in the town, only about half a dozen having been seen by members of the expedition. In regard to small-pox, general vaccination against this malady was carried out in 1905 and in March, 1909. It is interesting to note in this connexion that small-pox was present in 1908, and 1 per cent. of the inhabitants died with it. The entire mortality of the year was 45 per 1000. In 1907, when there was no small-pox, the death-rate was 27 per 1000. Practically all the deaths from small-pox were among children under nine years of age—that is, the majority of the children who died from the disease were born after the general vaccination performed in 1905, and therefore unvaccinated. This expedition is probably the most extensive medical survey that has ever been undertaken. Its value may be gathered from the summary of Dr. Strong in the *Philippine Journal of Science*, and the conclusions arrived at for the amelioration of the undesirable conditions found.

In addition to the periodical despatch of small expeditions to our African protectorates and colonies for the study of one disease, might it not be possible for our two leading schools of tropical medicine to bring together a British medical expedition for the combined investigation of the conditions of life in some populous centre in the hope that the various examinations made synchronously would elucidate much that remains as yet unknown with regard to the general status of the people, Europeans and natives alike, their average health and sickness, their surroundings, and the pests to which they are exposed? The conditions of life in one town are similar in many respects to those of other towns and villages in the same belt of country, and much might be gathered from a comprehensive study such as that which has been undertaken, and successfully carried out, by the Philippine Government.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

City Analyst's Report.

DURING 1909 2855 samples were submitted to analysis. Of these, 2105 were taken under the provisions of the Sale of Food and Drugs Acts. Of the 2105 samples 1954 were genuine, 19 contained preservatives only, and 132 were adulterated in other ways; 850 samples sold as "milk" and 5 sold as "separated milk" were analysed. The samples of separated milk were all of uniform composition and complied with the Board of Agriculture regulations. Of the 850 "milk" samples 7 were adulterated with boric acid and 3 with formic aldehyde; 5 of the samples containing boric acid were sold by one wholesale dealer who was prosecuted and fined £15; 64 samples were deficient in fat or other solids. 782 samples of butter, 4 samples of margarine, and 5 samples of proprietary-name butter were analysed; 49 samples of butter contained foreign fat and 2 excess of water, and 16 prosecutions were instituted.

Queen's Hospital.

Dr. Leonard G. Parsons has been elected to the post of honorary pathologist. Dr. Parsons, who received his medical education at Birmingham, and was formerly house physician to the late Dr. Foxwell, has recently held the post of casualty officer at the Hospital for Sick Children, Great Ormond-street, London.

The Late Mr. F. V. Milward.

The General Hospital has received a severe loss by the early death of Mr. F. V. Milward, who occupied the posts of assistant surgeon and surgical registrar. He was a hard-working officer, who did not spare himself in advancing the interests of the hospital, and had already gained a considerable reputation as an operating surgeon.

April 12th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Conquest of Consumption.

SUCH was the title of an address delivered by Dr. Arthur Latham at the annual meeting of the Manchester and Salford Sanitary Association. The title was chosen to impress on his audience the fact that many who were daily brought in contact with the disease held that it was possible to eradicate consumption from our midst within a generation. He said that the cause was known, the disease could be prevented, it could be detected, and could be cured. Nor was it hereditary, though some were more susceptible of infection than others. One part of the tasks of conquest was to raise the standard of health of the community by dealing with slum property and overcrowding. This, of course, would be most desirable, but it seems very doubtful if slums and all their evils can be got rid of in a generation, seeing how many generations have been taken to bring them into their present state and while human nature, not altogether perfect, remains what it is. However, by all means let the effort be made. He pointed out that milk and butter were frequent sources of infection, and that to prevent this it was enough to heat all milk to 140° F. for 20 minutes. The sale of milk containing tubercle bacilli should be made a criminal offence. He laid stress on the necessity for early detection and advocated the establishment of anti-tuberculosis dispensaries, which were cheap, and detected the disease in a curable stage. He spoke well of sanatorium treatment, and made out by some rather elaborate figures that the cost of the treatment of all the consumptives of the country would be less than the present cost of the disease. Education and organisation were necessary, with many other things that presuppose a sane determination on the part of the community to deal with this scourge. The education of the community will be one of the most difficult tasks. It was necessary to organise a pure milk-supply by inspection of farms and dairies, by rigid enactments as to the sale of milk, butter, and cream, and by the supply of milk from healthy cattle or in pasteurised form. "An efficient anti-tuberculous dispensary for every 300,000 persons should be organised, and in Manchester the cost for two would not be more than £1000 or £1500. They would also want to organise certain open-air schools; and a sufficient supply of sanatorium beds, with arrangements for the payment of the wife and family when the breadwinner was away regaining health. Most of this could be done at a little cost per head. If Manchester and other municipalities would take the matter up they would be astonished at the results of a few years' hard work and coöperation." Dr. Latham sketched the outline of a most noble crusade, though the carrying of it out will be hard. From the report of the Manchester and Salford Association it would seem that the corporation recently lost the chance, "in consequence of delay in dealing with it," of acquiring a property very suitable for a Manchester sanatorium. As is the case with many societies having the good of the community for their object, the Manchester and Salford Sanitary Association is not supported with sufficient generosity, and this is not creditable to either the humanity or the judgment of the Manchester people.

Medical Missions and the Poverty of Medical Men.

On April 8th Mr. Andrew Boutflower, senior honorary surgeon to the Salford Royal Hospital, presided over a public meeting held in the Manchester Memorial Hall on behalf of the Medical Mission department of the Society for the Propagation of the Gospel. He thought that every medical missionary should be in Holy Orders, though this, of course, could not apply to the female medical missionaries, who alone in many lands can gain access to their sisters. But he did not think they could reasonably expect much pecuniary support from the medical profession. They heard a great deal nowadays about the poverty of the clergy,

but the poverty of medical men was as bad and was gradually getting worse. If the incomes of all medical men were pooled he did not think the average would come to more than £200 a year. Dr. Lucy Pinniger (Oldham) said that in her visits to schools in the course of her duties she saw among the children much suffering from misery and disease arising from parental ignorance, and if this occurred in England how much it must be intensified in countries like India, Africa, and China. There was an appallingly high death-rate of women and children in India, and it could only be put an end to by medical missionaries, particularly by women medical missionaries. This certainly is a field in which qualified medical women may do good work. The Rev. J. Anderson Robertson, secretary, also spoke on behalf of the cause.

The Infirmary.

The amount received from the Manchester and Salford Hospital Saturday and Convalescent Homes Fund this year is £693 16*s.* 6*d.* The medical board has forwarded a resolution to the board of management to the effect that the Central Branch should be provided with beds, and the former board suggests that there should be 12, to be divided into six wards. A statement appeared a short time since in a local paper as to the income of the infirmary, which the chairman, Sir William Cobbett, said was not quite accurate. The actual income was £27,616, but the expenditure instead of being as stated (£27,382) was £35,494. This unfortunate disproportion between income and expenditure is too common with most of our medical charities.

Rivers Pollution.

A meeting of the Mersey and Irwell joint committee was held on April 5th, when Mr. Scudder, the chemical adviser, reported that of 38 samples of sewage effluents from the works of local authorities, 16 were good, 12 fair, 5 unsatisfactory, and 5 bad. After all the years during which the work of purifying our rivers has been going on, this does not seem a very triumphant result. One feature is that some of the most powerful authorities seem to be either careless or obstructive. The clerk was instructed to write to the Manchester corporation, the Bolton corporation, and the Tyldesley urban council "with reference to the unsatisfactory character of the effluent obtained from certain of their sewage works." "Unsatisfactory" must be a very familiar word to the clerk.

Epidemics in Cheshire.

Rather serious outbreaks of sickness have been occurring recently among school children in the districts about Altrincham and Sale. Mumps has been prevalent at Ashley and measles at Northenden, and Mr. T. W. H. Garstang, the county school officer of health, has received a letter from the rector of Mobberley asking him to close the schools there as there were a hundred cases of measles in the parish. Both mixed and infant schools have been closed.

April 12th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Extension of Medical Teaching in Glasgow.

AN inquiry under the Private Legislative Procedure (Scotland) Act, 1899, was held in the New Justiciary Court, Glasgow, last week, into the Provisional Orders promoted by the University of Glasgow, the Muirhead trustees, and the governors of St. Mungo's College. The three orders being inter-related were heard by the Commissioners as one group. The University order sought to alter the constitution of the deeds of endowment of the two chairs of clinical medicine and clinical surgery in the University. These, it was proposed, would be transferred to the Royal Infirmary, at which the professors would give both systematic and clinical instruction to students of the University without distinction of sex. Under the Muirhead order power was sought to abrogate the scheme prepared by the Muirhead trustees and approved by the Court of Session in 1889, by which it was intended to build and equip a college for the education of women by women, the changed circumstances brought about by the Carnegie Trust endowment in favour of Scottish Universities having rendered the proposed college unnecessary in the public interest. The St. Mungo's College order was also necessitated by the same changed circumstances in medical education. By the complete scheme which was proposed, the two clinical chairs in the University, the emoluments of which amount to £112 a year, would be increased by the payment by the Muirhead trustees of £400 to the chair of medicine, to be known in future as the Muirhead chair of medicine; and by the payment of £400 by the St. Mungo's College to the chair of surgery, to be known in future as the St. Mungo's chair of surgery. Two other chairs to be founded by the Muirhead trustees and the St. Mungo's College respectively were a chair of obstetrics by the Muirhead trustees of £400 per annum, and a chair of pathology by the St. Mungo's College of £600 per annum. The four new professors would teach at the Royal Infirmary and be members of Senate of the University and examiners in their subjects. The Muirhead trustees were also to make a grant of £1200 to the Glasgow and West of Scotland Technical College for a women's common room, cloakroom, &c., and were further to found four scholarships for women of £35 each. In addition to this the trustees were to found post-graduate scholarships of the value of £50 each at the Royal Samaritan Hospital for Women and the Royal Hospital for Sick Children. Dr. D. C. McVail, a governor of the Victoria Infirmary, objected to the Provisional Orders on the ground that they proposed to found at the Royal Infirmary a fragmentary medical school, as against a complete medical school at the Victoria Infirmary as intended by the late Dr. Muirhead. Dr. Marion Gilchrist, the first woman to get a medical degree from any Scottish university, objected on the ground that this scheme did not bring any nearer what those interested in the medical education of women had been striving for—viz., equal teaching with the men. According to Dr. Gilchrist, Dr. Muirhead had intended that women under his scheme should have house-surgeonships in the hospital with which his proposed college for women was to be affiliated, but if the present scheme were passed they would not get such posts. If the scheme were thrown out she thought it would improve the women's chances of getting into Gilmorehill, because in the two Universities in Scotland where women had no separate college they got straight away into the Universities. After the Commissioners had listened at considerable length to those for and against the scheme they found the preamble to the three Provisional Orders proved.

Glasgow Maternity Hospital.

The annual report of the Glasgow Maternity Hospital which has just been issued states that 4734 cases have been treated in the hospital and branches during the past year, being an increase of 350 over the previous year and almost 1000 over the total for 1907. The year's work has demonstrated the thorough suitability of the new hospital. The directors had intended to convert the adjacent old hospital building into wards and theatres suitable for gynæcological work. They had, however, been advised that it would be more economical and more efficient to convert the old hospital buildings into a home for nurses. This rearrangement would leave plenty of beds for maternity work and afford a sufficient number for gynæcological cases. The cost of the alterations on the former buildings was estimated at about £2000. This, added to the balance of the cost of the new buildings still unpaid, made the amount of capital still required £22,000.

School Medical Officer for Paisley.

The Paisley school board recently unanimously appointed Mr. Andrew Gilmour, M.D. Edin., D.P.H., assistant and deputy medical officer of health of Paisley, school medical officer of the burgh. The salary is £350, rising biennially by £25 to a maximum of £400.

Honour to a Perth Practitioner.

Dr. David H. Stirling, the oldest medical practitioner in Perth and founder of the Perth City Mission, was made the recipient of an illuminated address on the occasion of the mission's jubilee. Considerably over 80 years, Dr. Stirling has given up general practice, but he still takes an active personal interest in The Hillside Homes, which were established mainly by his exertions.

Regimental Gift to Montrose Infirmary.

The officers of the now disbanded Forfar and Kincardine R.G.A. (Militia), a regiment which had its headquarters in the town from its inception over 50 years ago, have decided to give the Montrose Infirmary certain funds, amounting to

£211 8s. 6d., to be used for the benefit of any old members of the regiment who may require treatment at the institution.

IRELAND.

(FROM OUR OWN CORRESPONDENT.)

The Apothecaries' Hall of Ireland and the General Medical Council.

AT a meeting of the General Medical Council in November, 1909, the education committee reported upon an application from the Apothecaries' Hall of Dublin that its preliminary examination should be recognised by the Council in a favourable sense. The report of the education committee stated that it in no way wished to discourage the legitimate efforts of the Apothecaries' Hall, but the committee did not consider it right that a body concerned purely with medical education should conduct a preliminary examination in general education. The Apothecaries' Hall of Ireland consequently addressed the Privy Council praying that the General Medical Council might be directed to re-schedule the preliminary examination of the Hall as sufficient for registration in the Medical Students Register. To this the Privy Council has replied that the power of the Privy Council under Section 19 of the Medical Act, 1886, to notify their opinion to the General Medical Council is limited (apart from the specific cases mentioned in the opening part of the section) "to cases in which the Council fails to exercise any power or perform any duty or do any act ..... imposed on or authorised to be done by the General Council under the Medical Acts." The Privy Council further points out that inasmuch as neither the establishment of a register of medical students nor the recognition of particular examinations in general education as qualifying medical students for registration therein is an "act or thing vested in or imposed on or authorised to be done by the General Council under the Medical Acts," the subject matter of the petition does not fall within the purview of the Council.

Workmen's Compensation Act in Ireland.

Dr. T. S. Kirk, one of the medical referees under the Workmen's Compensation Act, introduced last week before the Ulster Medical Society a discussion on the Workmen's Compensation Act, in which he dealt with the question under three heads—(1) the workman, (2) the employer, and (3) the insurance companies. He showed that decisions such as that in the recent "aneurysm case," the case of "heat-stroke," and other well-known cases in which, on appeal, the House of Lords decided they were accidents, were completely altering our ideas as to what an accident was legally, and it was a significant fact that in the most recent text-books on surgery writers were more chary of saying (as was done formerly so often without sufficient proof) that a given surgical condition was caused by an accident. The legal definitions of accident recently established were making insurance companies feel that they must raise their premiums, while, on the other hand, employers were deciding that before hiring anyone to work they must be medically inspected, and workpeople would soon be considered old at 45 years of age. It was also clear that the Workmen's Compensation Act, as at present being carried out, must lead on to State sickness insurance; and it was also likely that the insurance companies, in cases of accidents, would not rely so much as formerly on hospital surgeons at whose institutions the cases were treated, but would employ specialists paid by themselves to attend those injured, and who when necessary would give evidence. From the debate which followed it is clear that great dissatisfaction prevails in medical circles as to the way the Workmen's Compensation Act is being administered—either it will have to be altered or the alternative is State Insurance. Many medical men object to be badgered in the witness-box or to be asked to swear exactly as to what are after all pure probabilities, and it will soon arise that those medical men whose opinion would be of the greatest value will not put themselves in the way of giving evidence. The best method would be for both sides to allow the medical men to consult together and come to an agreement as to what they considered was the fair view of the case, but to this, presumably, the legal profession would never agree.

Poor-law Administration.

Considerable interest is being taken in Belfast in the projected changes in the Poor-law system, and an association has been formed for the discussion of questions relating to Poor-law reform. In Ireland no part of this question is more important than that of medical relief as it interests both the poor and the profession, and both the Irish Medical Association and the Irish Committee of the British Medical Association are taking a plebiscite of the Poor-law medical officers as to what plan they would regard as best for dealing with the matter—in other words, should the medical service under the Poor-law be a State one, entered by examination and paid out of the Consolidated Fund; or a county medical service; or should it remain unaltered with the addition of compulsory superannuation on retirement?

Trypanosomiasis and Sleeping Sickness.

At a meeting of the Belfast Natural History and Philosophical Society on April 6th Professor St. Clair Symmers gave an interesting popular lecture on the above subject, very fully illustrated with lantern slides. At its conclusion he was accorded a hearty vote of thanks from the large audience which was present to hear him.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Congress of Medical Practitioners.

AT the Congress of Medical Practitioners, which has just concluded its sittings in Paris, the president of the committee of organisation opened the proceedings with an address, the election of officers followed, and the reading of papers then commenced. Among the more important communications mention may be made of one by M. Marro on irregular admissions and registrations in the medical schools, and one by Dr. Tourtourat on the limitation or non-limitation of students in the medical schools. The authors and subjects of the other principal papers were as follows: Dr. Bolliet, on free choice and the mutual aid societies; Dr. Vallat, on free choice of doctors and industrial undertakings; Dr. Bresselle, on the increase of medical fees; Dr. Bertillon, on abortion regarded from a medico-legal point of view; Dr. Levassort, on the illegal practice of medicine; Dr. Lafontaine, on medical unions and medical teaching; Dr. Le Fur, on the Superior Medical Council; Dr. Delpeut, on competitive examinations for admission to the medical schools; Dr. L. Archambault, on hospital administration in France and other countries; Dr. Duclercq, on the administration of the public health services in foreign countries; Dr. Wicart, on the law of 1902 with reference to public health; Dr. Maurice Faure, on the present state of physical education in France; Professor Kutner of Berlin, on supplementary medical teaching in Germany; Dr. Koenig, on hospital and nursing organisation in the United States of America; Dr. Kolbe, on hospital administration in Germany; and Dr. Campinchi, on the relation of medical unions to public health questions.

A Franco-Belgian Medical Convention.

The French and Belgian Governments, by successive arrangements concluded between the years 1895 and 1909, have sanctioned reciprocity of notification by the local authorities on the respective frontiers in cases of epidemic disease reported in the districts of such authorities, the object being to improve the sanitary and medical supervision of the districts in question. It is announced in the French *Journal Officiel* that the diseases notifiable under this system are Asiatic cholera, plague, typhus fever, typhoid fever, small-pox, scarlet fever, diphtheria, measles, dysentery, contagious ophthalmia, puerperal fever, cerebro-spinal meningitis, and in general all epidemic and transmissible diseases. A similar convention has been entered into with respect to some infectious diseases of animals. The French departments in which the new system will take effect are the Nord, the Aisne, the Ardennes, the Meuse, and the Meurthe et Moselle, the corresponding Belgian provinces being West Flanders, Hainault, Namur, and Luxembourg.

BUDAPEST.

(FROM OUR OWN CORRESPONDENT.)

Pellagra in Hungary.

A RECENT report of the Public Health Service of Transylvania (the south-eastern part of Hungary) announces the appearance of pellagra, which is spreading rapidly. As generally held, the disease is due to eating damaged maize, and the prevalence of it is not surprising in view of the fact that maize is the staple food of the peasantry in this part of Hungary. The maize is rendered unwholesome by the modern intensive method of cultivation, the grain being harvested while still unripe, with the result that putrefaction occurs. In parts of Italy, especially in Lombardy and Piedmont, and also in Roumania, pellagra is even more common than in Hungary. The Government of Hungary has distributed wheat flour among the indigent inhabitants of South Hungary, who are chiefly peasants of Roumanian origin. The disease itself is by no means severe, though some patients suffer from mental disturbance which does not yield readily to treatment. Many cases of pellagra recover when supplied with wholesome food.

Typhus Exanthematicus in Budapest.

In 1908 some cases of acute febrile illness which occurred in Budapest perplexed even the hospital experts on account of the unusual character of the eruption, and in the result such patients as presented these symptoms were isolated in the hospital for infectious diseases. Here Dr. Gerlocsy, director of the institute, at once recognised that the patients were suffering from typhus exanthematicus and accordingly advised the municipal authorities to issue strict rules for the isolation of all the cases. This energetic action had a good effect, and in June, 1908, the last case was discharged from the hospital. From that time no case was notified until Jan. 8th of the present year, since which date all suspicious cases have been conveyed to the St. Gellert Hospital. Disinfection of places that have been occupied by patients is carried out as far as possible, but the want of sufficient disinfecting apparatus and of a skilled staff is a great obstacle. This work is, as a rule, undertaken by order of the local magistrate, and in that case no charge is made to the public. The usual disinfectant is formaldehyde, employed in the state of vapour or spray. Portable personal belongings are disinfected by means of high-pressure steam in special apparatus, of which there are at present four very large plants available in Budapest.

Ice Production, Natural and Artificial.

The uncommon mildness of the winter, during the whole of which there were only two cold days, threatens us with an ice famine. The seriousness of the situation thereby created may be best understood from the fact that all the town magistrates have petitioned the Minister of Public Health to establish State-aided ice factories. Budapest alone needs 60,000 centen (6,000,000 kilogrammes) of ice in a single summer day. The ice factory in connexion with the slaughter-house and one private company are able to supply only 10,000 centen—i.e., one-sixth of the total demand. Hitherto there has been a sufficient supply of natural ice gathered in winter from artificial lakes, because from a hygienic point of view river ice is unfit for use. The hospitals of Budapest have resolved to establish a separate ice factory capable of supplying their own needs as well as those of the other medical institutions and of the apothecaries. The hotel-keepers have also formed a limited company to ensure a sufficient quantity of ice for their requirements. Provincial towns intend to raise money to establish refrigerating machinery in connexion with their slaughter-houses. The ice famine will naturally have its sad consequences, chiefly to be felt by the poorer classes. In Budapest some private companies have formed a trust to raise the price of ice by about 80 per cent., and certain Members of Parliament have thereby been led to put questions to the Minister of Public Health on the subject. In towns and in the larger villages it will be possible to procure ice at a considerable cost, but the butchers and other traders in villages will probably be placed at some disadvantage.

April 11th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

The Ontario Medical Council.

THROUGHOUT the province of Ontario there has been manifested lately a great deal of unrest in the medical profession owing to the manner in which the governing body of the profession has conducted affairs, as well as considerable dissatisfaction with the constitution of the council. The contention has centred around the composition of the council, on which there remain several representatives of so-called university bodies which only exist on paper, as they have either long since abolished their medical teaching faculties or even in some cases given up their degree-conferring powers. It is felt that but three universities—namely, Toronto, Queen's, and the Western University at London—should have representatives on the council, each of these three having an active teaching faculty in medicine. The West Toronto District Doctors' Association met on March 1st and unanimously adopted resolutions looking to a correction of the existing abuses and affirming their belief in this principle. The meeting also favoured the revision of the entire representation of the council, reducing university representation as above, the territorial representatives from 17 to 9, and the homœopathic from 5 to 2. Apparently, too, the Ontario Medical Council is spending far too much money, as its capital account has recently been drawn upon to the extent of some $10,000. The meeting called for a full exposition of the finances of the council.

Rabies in Ontario.

There has been a widespread outbreak of rabies all over the western portion of the province of Ontario. Some three years ago a small rabid dog ran across the International Bridge at Buffalo into Ontario and bit other dogs, and from that time to the present isolated cases have from time to time been reported. Gradually cases grew in numbers until a few weeks ago the federal and provincial authorities united to issue an order requiring all dogs to be muzzled or kept on the chain. Some 50 people bitten by dogs have had to go to New York for treatment at the Pasteur Institute. This necessarily involved considerable expense, so the Ontario Government sent Dr. Hodgetts and Dr. Amyot of the Provincial Board of Health to New York to study the treatment. Now these cases are being treated in the Toronto General Hospital and the Hospital for Sick Children, Toronto. So far there has been only one case of hydrophobia, a boy aged ten years, who died recently in the Hamilton General Hospital, the only case in Ontario in the remembrance of the present generation of physicians. All the patients who underwent the treatment in New York so far have recovered.

Montreal General Hospital Extension.

Work has been commenced on the reconstruction of the Montreal General Hospital, and when completed it will be one of the finest structures of its kind in Canada. The extension will include 38 additional private wards and accommodation for some 80 extra beds in the three new public wards. There will be accommodation for 28 extra "semi-private" patients, and the present capacity of the hospital (about 250 beds) will be pretty nearly doubled. A new operating theatre will be constructed which will be modern in all its appointments, and in connexion therewith there will be an assembly room and lecture room. Directly opposite the hospital a large vacant plot has been secured for conversion into a pleasant flower garden.

Medical Education in Toronto University.

In his report to the governors of Toronto University the Dean of the Medical Faculty states that the candidates for the final examinations, during the last two years especially, were not properly equipped and that better methods of teaching are necessary. These facts have been generally known throughout the province, and a year ago at the Ontario Council examinations there was a great deal of complaint at the number of candidates who were "ploughed." The dean is giving careful consideration to the subject. The *Canadian Practitioner and Review* commends the frankness and honesty of the dean in giving the matter publicity. A writer in the same journal considers that it is a serious mistake to appoint juniors to positions as clinical teachers in practical subjects,

and that too many of the older and more experienced men have been laid on the shelf. He thinks also that it is a mistake to allow the didactic lecture to go by the board.

April 1st.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Plague.

THE plague returns for the week ending Feb. 26th show 18,992 deaths for all India and Burma as compared with 18,922 for the week preceding. The Bombay Presidency reported 1043, Bengal Presidency 2367, the United Provinces 7936, the Punjab 3697, the Central Provinces 1583, Rajputana 1833, and Burma 357. For the week ending March 5th similar returns give 21,514 deaths for all India and Burma, of which Bombay Presidency reported 1008, Bengal Presidency 2554, the United Provinces 8260, the Punjab 6227, the Central Provinces 1300, Rajputana 1708, and Burma 300.

A Discussion on Plague at the Viceroy's Representative Council.

The new Councils discuss many subjects, and it was not likely that plague would escape notice, for there are some critics who hold the Government responsible for all the ills that afflict the people of India. When, however, it comes to assertions that official shortcomings in the matter of sanitary improvements are responsible for the prevalence of plague, and that Europeans escape the disease because their welfare is more closely regarded than that of the people at large, it is time for plain speaking. In the Viceroy's Legislative Council at a recent meeting the Director-General of the Indian Medical Service had to traverse statements of this kind, and his remarks should have some effect in influencing public opinion. Surgeon-General Lukis follows the highest scientific authorities in tracing the causation of plague to the rat and the rat flea, and shows that the question is one of domestic hygiene and not of general sanitation. The "domestication" of the rat must be discouraged in every way, for so long as it remains a house-dweller so long will the danger of plague continue. At present the rat is encouraged to live in and near houses by reason of grain being stored in the rooms, by scraps of food being carelessly thrown about, and by rubbish being allowed to accumulate in which nests can be made. Sanitary measures pure and simple will not act as remedies so long as these conditions are allowed to continue. Such measures are good in their way so far as the general health of the people is concerned, but they will fail to check epidemic plague. Europeans in India enjoy practical immunity from the disease because the rat is never permitted to gain a footing in their houses. The Japanese have stamped out plague by an extraordinary campaign against rats. When the dwellers in Indian cities and villages will listen to the oft-repeated warnings that the rat and the rat flea are their most dangerous enemies, plague in epidemic form at least will die out. In the Viceroy's Legislative Council the Honourable Pandit Mohan Malaviya and Mr. Bhupendra Nath Basu, both representative members, laid stress upon the fact that Europeans in India escape the ravages of plague, whereas the Indian population suffered terribly owing to the failure of Government to carry out a policy of sanitary improvement. The reply given by Surgeon-General Lukis is worth reproducing in full. He said: "I did not intend to speak on this occasion, but I feel bound to correct the misapprehensions under which the hon. members who have last spoken are labouring with reference to the causation of plague. They infer that the reason why Europeans escape this fell disease is that they are living in more sanitary surroundings than those which obtain in Indian cities and villages. Now, sir, if there is one thing that we have learnt in the last 13 years it is that plague has nothing whatever to do with pollution of the soil, contamination of water-supply, or defective drainage, and large sums of money have been spent by Government without any effect as regards the checking of the disease. Recent discoveries have proved that plague is essentially a disease of rats, and that the medium of communication between rat and man is the rat flea. What happens when plague breaks out amongst human beings is this. First of all the rats are attacked. So soon as this happens they begin to run away from the infected house, but in so doing they leave their nests behind them and in these nests a large number of rat fleas. Now, ordinarily the rat flea will not bite human beings, but when no rats are forthcoming they are forced to do so, and thus they convey the infection to the inhabitants of the house and a plague epidemic is started. It is obvious, therefore, that the question of the prevention of plague becomes one of domestic hygiene. What is wanted is to teach the Indian public the danger of allowing the rat to remain a domestic animal, and to advise them to try and prevent this by giving up the habit of storing grain in the house, throwing remnants of food about in its vicinity, and by allowing collections of rubbish behind which rats can make their nests. So long as the rat remains a house-dweller so long will the danger of plague continue; and until this fact is appreciated it is useless for Government to squander large sums of money on sanitary improvements of doubtful value. I wish, however, to state distinctly that I must not be understood as deprecating sanitary improvements on general lines. I merely wish to point out that, as regards this particular disease of plague, it is the habit of the people and not the want of care on the part of Government which is largely responsible for the persistence of the epidemic."

March 19th.

NEW ZEALAND.

Annual Report of the Public Health.

IN his report the chief health officer (Dr. J. M. Mason) draws attention to the steady advancement which is being made towards the provision of open-air shelters for the indigent consumptive. Ever since the Department of Public Health of New Zealand was set up in 1900 the campaign against tuberculosis has been carried on most vigorously. The hospitals in New Zealand, as in most of the colonies, are supported partly from the local rates and partly from the consolidated revenue. The State established in 1902 a very fine sanatorium, capable of accommodating about 62 patients, and in most of the hospital districts there are fine annexes for the reception of cases of consumption. In the Christchurch and Wellington districts elaborate and up-to-date sanatoriums have also been provided. Good work appears to have been done at a tree-planting camp which was established for "cured" consumptives. The planting is done under the supervision of the Lands Department, and the men receive 8*s*. for planting 1000 trees. The camp is almost self-supporting and the Government has a first lien upon the worker's wages for the cost of his keep, &c. This is an excellent State experiment and already "several who have been 'hardened off' at Karere have gone back to their ordinary work quite recovered." There would appear to be the same difficulty in providing work for the "cured" consumptive in this Britain of the South as there is in England. Speaking of this Dr. Mason says: "Only those in intimate contact with the lives of the men and women who pass through our sanatoria know what a 'hopeless dawn' the day they leave the institution often seems to the 'cured.' Though well, they are debarred by reasons of prudence from engaging in indoor work, and their physical condition does not permit of their competing in the open mart of unskilled labour. What are they to do? Friends tire of keeping them, the lodging-house-keeper is sorry but his other clients complain, and so they must seek shelter where their neighbours are less exigent. This shelter they find only amongst the poorest. Ill-fed, poorly clothed, dispirited at the non-finding of work, he soon falls back, his cough returns, and—to put it briefly—all the money, care, and skill that has been expended upon him is, from a public health point of view, wasted. It would have been cheaper, nay, in some senses it would have been kinder, to have shut the door upon him when he first knocked." Suitable work for the "cured" is undoubtedly the great problem.

The birth-rate increased by 3·37 per cent. in 1908 over that of 1907. New Zealand once again holds the enviable position of having the lowest death-rate almost in the world—namely, 9·57 per 1000 persons living. The principal causes of death were: cancer, 6·95; tuberculosis (general), 8·97; and accident, 6·03.

Another case of leprosy was reported. The patient is a

Maori. There are now some three cases known amongst the Maoris and one in a white man. There would appear to have been no epidemic of any severity in the Dominion in 1908, although there was a severe outbreak of enteric fever in Gisborne. This, however, was traced to the generally insanitary condition of the town. According to Dr. Pomare, the native health officer, cancer is a rare disease amongst the Maoris, but tuberculosis claims many victims. A great deal of valuable work has been done amongst the natives and many of the old insanitary "whares" have been replaced by up-to-date houses. Some interesting observations on the height and weight of the boys attending the Wanganui school and of the girls attending the High School in Dunedin appeared in the last report. Further data have been collected by Dr. J. S. Purdy with respect to Auckland. It seems a great pity that there is no general examination of the scholars attending the schools. It would be most interesting to see the result upon the race of the climatic and social conditions which obtain in young countries like New Zealand. Generally speaking, it would seem that the young New Zealander is, age for age, taller and heavier than his compeer in England. This statement has, however, to be accepted with some reservation because of the small amount of data at the command of the chief health officer. It would appear that the European boy starts (at 10 to 11) a little taller than the Maori, but nearly seven pounds lighter. In the matter of height the Maori still gains upon the European until the age of 15 to 16 is reached, when the heights are equal. The weight of the Maori is maintained about equal, until at the ages of 13 and 16 years the Maori boys are one stone heavier than the European.

A large amount of valuable work was done in the various laboratories both in a chemical and bacteriological way, but vaccination and democracy would appear not to walk hand in hand. The returns for last year show that only 4·7 per cent. of the children born had been vaccinated, and this despite the ardent advocacy of the health officials. Some day the Dominion may regret this. In thanking the various officers Dr. Mason intimates that he has resigned the position of chief health officer—a post which he has held since the inception of the department in 1900—to take up that of consulting medical officer to the New Zealand Government in London. Dr. Pomare, in his statement upon the "sanitary conditions of the Maori," which is included in this report, pays an eloquent tribute to the appreciation felt by the natives for the altered conditions wrought in their lives by the Health Department under Dr. Mason's captaincy.

Obituary.

FREDERIC VICTOR MILWARD, M.B., B.C. CANTAB., F.R.C.S. ENG., L.R.C.P. LOND.

WIDESPREAD regret is felt at the death of Mr. F. V. Milward, which occurred at his house at Edgbaston on March 31st after a few days' illness from pneumonia following influenza. Mr. Milward was the second son of the late Colonel Victor Milward, a member of the well-known Redditch needle manufacturers, and was in the fortieth year of his age at the time of his death.

Born at Redditch and educated privately until he entered Clare College, Cambridge, he took the degrees of B.A. Cantab. in 1891 and M.B., B.C. at the same University in 1895. In the same year he also qualified as M.R.C.S. Eng. and L.R.C.P. Lond. He completed his curriculum at St. Thomas's Hospital, where he held some minor appointments. His first resident appointment was that of house surgeon at the General Hospital, Birmingham, in 1896. From there he went to the Seamen's Hospital, Greenwich, returning to the General Hospital in 1898 as resident surgical officer. He afterwards held the posts of casualty assistant surgeon, assistant surgeon, and surgical registrar and junior surgical tutor at this hospital. He obtained the F.R.C.S. Eng. in the year 1900. Shortly after this he was elected resident surgical officer at the General Hospital, Birmingham. Here he remained for some three years and was afterwards appointed one of the assistant surgeons to the hospital. He also held the posts of surgeon to the Orthopædic Hospital and surgeon to out-patients at the Children's Hospital, Birmingham. In his many positions he discharged his various duties with credit to himself and to the satisfaction of the committees of the various public institutions with which he was associated. In 1906 Mr. Milward published a work upon "Diseases of the Rectum," and also contributed to the study of allied subjects to various medical periodicals. A paper on Rectal Carcinoma by him appeared in THE LANCET of Nov. 23rd, 1907. Another paper, on Congenital Piles, appeared in THE LANCET of June 1st, 1907. His last paper upon a case of death under spinal anæsthesia, as late as March 26th, is an evidence of his conscientious desire to fairly give to others the benefit of his own practice.

Mr. Milward was a man of upright, manly, and straightforward character. The keynote of his life was thoroughness; to whatever he put his hand, whether it was work or play, he gave his best. Careful and painstaking in the performance of his duties, his accurate knowledge and large surgical experience gave strength and value to his opinions. Naturally of a retiring disposition, "showiness" in method or manner was not deemed worthy of cultivation, but no service was accounted too heavy when the welfare of his patients had to be considered, and his loyalty to them and to his friends was unbounded. His amiable disposition, generous bearing, and many fine qualities of mind united to him a large circle of friends, who now mourn his premature decease. To the local medical societies he made many contributions, and at the time of his death he was surgical secretary to the Midland Medical Society. Besides his strictly professional work, Mr. Milward interested himself and did much strenuous spade-work as honorary secretary to the Birmingham Branch of the Red Cross Society, and to his efforts the present flourishing condition of this particular city branch, as distinguished from the county branch, is due. In the Territorial Army he ranked as captain, *à la suite*, in connexion with the 1st Southern General Hospital, Territorial Force. He was looked upon as one of the most promising and skilful operators whose high ideals and unselfish character exemplified the best traditions of the medical profession. Mr. Milward married the daughter of Mr. B. Tilley of Edgbaston; he leaves a widow and one child. The funeral at Harborne Church on April 4th was conducted by the Archdeacon of Birmingham and the Rev. Canon Moss, and was attended by a large number of his colleagues and friends and representatives of various public institutions, whose presence testified to the high regard in which he was held during a short life affording a bright prospect of success.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. C. Botez, professor of external pathology in the University of Jassy.—Dr. Hennequin, member of the Paris Surgical Society.—Dr. Gréhant, professor of general physiology in the Museum of Natural History and member of the Paris Academy of Medicine.—Dr. Wilhelm Camerer, whose researches on the pathology of metabolism and other problems of physiological chemistry brought his name prominently before the medical public some years ago. The University of Tübingen conferred an honorary doctorate upon him in 1895 in recognition of his physiologico-chemical researches. His age at his death was 67 years.

AN EXHIBITION OF FRACTURES.—The *Société Internationale de Chirurgie* has just issued a circular with reference to an "Exposition de Fractures," to be held at Brussels in September, 1911, on the occasion of the third congress of the society. Dr. J. Lucas-Championnière is the president of this congress, M. A. Depage is the secretary-general, and M. L. Mayer is the secretary. Everything relating to the study of fractures will be exhibited, particularly various types of rare fractures; radiograms, drawings, plaster-casts, and moulds of the same; apparatus for the bloodless treatment, the rigid treatment, and the ambulatory treatment; extension apparatus; exhibits and documents relating to osteo-synthesis, and so on. The objects intended for exhibition should reach the secretary-general at 75, Avenue Louise, Brussels, from Aug. 20th to 31st, 1911, who will arrange for their receipt, installation, and return on the expiration of the congress. Exhibitors will be able to make demonstrations of their apparatus during the congress, and subjects will be placed at the disposal of exhibitors who require them. Special railway rates, it is hoped, will be obtained, as they were for the Cancer Exhibition in 1908. Further information and forms to fill up for those who intend to enter objects will be supplied by the secretary-general on demand.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the First Professional Examination, held on March 29th, 30th, and 31st, and April 1st and 2nd, the following gentlemen were approved in the undermentioned subjects:—

Biology.—Wilfred Herbert Alderton, London Hospital; William Guy Embleton Allen, St. Bartholomew's Hospital; Errington Atkinson, London Hospital; Cecil Bluett, Sydney University and London Hospital; Maurice Charles Breese, Westminster Hospital and King's College; Norman Briggs, Leeds University; Eric Catford, St. Bartholomew's Hospital; Percival Cheal, London Hospital; Hugh Forster Chillingworth, St. Bartholomew's Hospital; George Edwin Chissell, Middlesex Hospital; Edmund Sheppard Cuthbert, St. Bartholomew's Hospital; Gordon Robert Craig, Middlesex Hospital; Jean Crétin, St. Bartholomew's Hospital; George Stanley Deane, Robert Edmund Barry Denny, and James Angel Durante, London Hospital; Stanley Ernest York Elliott, St. Mary's Hospital; David Trevor Evans, University College, Cardiff; Sidney William Fisk, University College; Luis Hernando Garces, London Hospital; Cassidy de Wet Gibb, Guy's Hospital; Ernest Richard Gordon Greville, St. Thomas's Hospital; Henry Judson Grimshaw, Liverpool University; Douglas Noel Hardcastle, Technical College, Brighton; Arthur Herbert Harkness, Guy's Hospital; William Llewellyn Aplin Harrison, St. Mary's Hospital; Newton Hoffmeister, Middlesex Hospital; Richard Annesley Holmes, Guy's Hospital; Ifan Septimus James, University College; Edward Glyn Jones, Liverpool University; Gerald Patrick Kidd, St. Thomas's Hospital; Thomas Clatworthy Kidner, Middlesex Hospital; Holger August Hugo Kleberg, St. George's Hospital and King's College; Felix Edward Ricardo Laborda, Guy's Hospital; Annesley George Lennon-Brown, Westminster Hospital and King's College; James Stuart Leslie, James Arthur Liley, and Neville Hood Linzee, London Hospital; Louisa Margaret Lister, Bristol University; Henry Guy Ludolf, Leeds University; Henry Wingate Maltby, St. Bartholomew's Hospital; Gerald Struan Marshall, Charing Cross Hospital; Gerald Woffindin Maw, Birkbeck College; Alan Lawrence Miller, Birmingham University; Donald Samuel Eccles Milligan, St. Thomas's Hospital; George Stanley Mitchell, Westminster Hospital and King's College; Herbert Guy Moser, St. Bartholomew's Hospital; Wilfred Guy Stuart Neely, Guy's Hospital; Walter Justice Paramore, University College; John Meredydd Parry, University College, Cardiff; Ernest Noble Perham, University College; Haydn Peters, Charing Cross Hospital; Arthur Bennet Preston, London Hospital; Roberto Quesada-Jimenez, Costa Rica University and Guy's Hospital; William Ewart Patrick Rafter, Liverpool University; John Wootton Rammell and Charles Reginald Reckitt, London Hospital; Laurence Cecil Sebastian Roche, St. Thomas's Hospital; George Francis Rowcroft, St. Bartholomew's Hospital; Noel Humphrey Wykeham Saw, Guy's Hospital; Herbert Henry Silley and Sydney Frank Simpson, King's College; Peter de Safforie Smith, University College, Bristol; Cecil Spurling Staddon, St. Thomas's Hospital; Robert Cyril Wilmer Staley, Guy's Hospital; John Aylmer Tippet, St. Thomas's Hospital; Myles Denison Boswell Tonks, London Hospital; Ambrose Huntington Warde, St. Thomas's Hospital; and Norman Jeune Willans and Thomas Mansergh Wood-Robinson, Middlesex Hospital.

Chemistry and Physics.—Alexander William Charles Bennett, St. Thomas's Hospital; William McHutchison Binning, University College; Maurice Charles Breese, Westminster Hospital and King's College; Hugh Forster Chillingworth, St. Bartholomew's Hospital; George Edwin Chissell, Middlesex Hospital; William Lonsdale Cockcroft, Manchester University and Technical School, Rochdale; Stephen Walter Coffin, Guy's Hospital; Ernest Ivon Davies, University College, Cardiff; Philip Cuthbert Collingwood Fenwick, St. Thomas's Hospital; George Cowley Gell, Middlesex Hospital; Donald Herbert Hargrave, London Hospital; Oswald Ryle Horwood, M.A. Cantab., Cambridge University; Charles George Gordon Keane, St. Mary's Hospital; Felix Edward Ricardo Laborda, Guy's Hospital; Labib Abdul Malik, St. Mary's Hospital; Gerald Struan Marshall, Charing Cross Hospital; Walter Edgar Masters, London Hospital; Walter Justice Paramore, University College; Arthur Bennet Preston and John Wootton Rammell, London Hospital; Cecil Arthur Robinson, St. Mary's Hospital; Alan Filmer Rook, Guy's Hospital; Myles Denison Boswell Tonks, London Hospital; Eric Morse Townsend, Royal Technical Institute, Salford, and Chelsea Polytechnic; Norman Jeune Willans, Middlesex Hospital; and Ernest Jenner Wright, St. Mary's Hospital.

Chemistry.—Percy William Lavers Andrew, Technical College, Brighton; Edward Victor Briscoe, St. Mary's Hospital; Paulin Roger Chevreau, Guy's Hospital; David Trevor Evans, University College, Cardiff; Harold Percy Gabb, University College; Douglas Vernon Halstead, Guy's Hospital; Claude Osborne Hudson, Sheffield University; Aubrey Thompson Madin, Municipal Technical School, Birmingham; Noel Heathcote Seton Maelzar, Guy's Hospital; George Stanley Mitchell, Westminster Hospital and King's College; Edgar Stanley Rowbotham, Charing Cross Hospital; Noel Humphrey Wykeham Saw, Guy's Hospital; and William Ernest Wade, University College, Cardiff.

Physics.—Charles Theodore James Drobig, St. Mary's Hospital; Herbert Carr Duggan, Guy's Hospital; Arthur Geoffrey Pattison Hardwick, London Hospital; Harry Millett, Guy's Hospital; Arthur Rennie Muir, University College, Cardiff; Kenneth Montague Nelson, St. Mary's Hospital.

At the Second Professional Examination in Anatomy and Physiology, held on March 31st, and April 1st, 4th, and 5th, 94 candidates presented themselves, of whom 62 were approved and 32 were referred. The following are the names of the successful candidates:—

Charles Beresford Alexander, Liverpool University; Saravaiya Amritaraj, L.R.C.P. & S. Edin., L.F.P.S. Glasg., Madras Medical College and Edinburgh; John Vere Orlebar Andrew, London Hospital; Gilbert Bailey, Manchester University; Stephen Leonard Baker, London Hospital; John Henry Bennett, St. George's Hospital and King's College; Alured Charles Lowther O'Shea Bilderbeck, Cambridge University and St. Bartholomew's Hospital; Kareem Black, King's College; Bertram James Brewitt and Roger Orme Bridgman, St. Bartholomew's Hospital; Alfred Fisher Camp and Rowland Burnell Campion, Guy's Hospital; Eliezer Coplans, Liverpool University; William Dale, St. George's Hospital and King's College; William Agar Scholefield Duck, Middlesex Hospital; Maurice Dwyer, Leeds University; William Trevor Flooks, University College, Cardiff; William Kelsey Fry, Guy's Hospital; Alfred Noel Garrod, Cambridge University and St. Bartholomew's Hospital; Henry Albert John Gidney, Major I.M.S., L.S.A., F.R.C.S. Edin., D.P.H. Cantab., Calcutta and Middlesex Hospital; Leslie Price Harris, Guy's Hospital; Spencer Frederick Harris, Middlesex Hospital; Theodor Julius Juta Jeppe, Cambridge University and St. Thomas's Hospital; Hugh Percival Joseph, L.M. & S. Ceylon, Ceylon Medical College; Claude Kingston, Bristol University; Herbert Arnold Lake, M.R.C.V.S., University College Hospital; George Howard Strettell Letchworth, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; John Llewellyn David Lewis, Guy's Hospital; Harold Bishop Logan, Bristol University; Farquhar McGillivray Loughnane, St. Thomas's Hospital; Henry Leslie Messenger, Guy's Hospital; Robert Hamilton Miller, M.R.C.V.S., Edinburgh University; Arthur Stanley Morgan, Guy's Hospital; Owen Colville Morphy, Middlesex Hospital; Frank Andrew Miller Nelson, London Hospital; George Marshall Oakden, Middlesex Hospital; Robert Charles Parry, London Hospital; Claud John Burgoyne Pasley, Westminster Hospital and King's College; Edward Phillips, London Hospital; D'Arcy Power, St. Bartholomew's Hospital; George Brentnall Pritchard, Guy's Hospital; Arthur Leslie Hanworth Rackham, Middlesex Hospital; William Arthur Rail, St. Bartholomew's Hospital; Stanley Owen Raskbrook, London Hospital; Rachel Ricketts, L.M.S., Calcutta, Calcutta University; Pierre Roux, London Hospital; Alexander Elder Saunderson, Liverpool University; Samuel Arnold Sittampalam, L.M.S. Ceylon, Ceylon Medical College; Jack Garland Skeet, St. Thomas's Hospital; Alan Ker Soutar, B.A. Cantab., Cambridge University; Owen William Dyne Steel, London Hospital; William Vere Taylor Styles, Middlesex Hospital; Gordon Bower Sutton, B.A. Cantab., Cambridge University and King's College; John William Thomas, Leeds University; Thomas Ainsworth Townsend, King's College; Herbert Walker, B.A. Cantab., Cambridge University and St. Thomas's Hospital; Hamlet Mark Whelan, University College, Cardiff; Syer Barrington White, B.A. Oxon., Oxford University and Westminster Hospital; William Cuthbert Whitworth, Guy's Hospital; Stanley Wickenden, Guy's Hospital; Charles Eustace Williams, Charing Cross Hospital; and Oscar Reginald Lewis Wilson, Guy's Hospital.

At the quarterly examination in Practical Pharmacy held on April 7th the following gentlemen were approved:—

William Rawson Barlow, Middlesex Hospital; James Cowan, Manchester University and private study; Charles Alexander Robertson Gatley, Guy's Hospital; Willoughby Gordon Grant, London Hospital and private study; Philip Hamill, M.A. Cantab., D.Sc. Lond., Cambridge University and St. Bartholomew's Hospital; Arthur Herbert Harkness, Guy's Hospital; Augustus Joseph Hickey, Westminster Hospital; Sydney James Higgins, B.A. Cantab., Cambridge University and London Hospital; Ivor Robert Hudleston, St. Bartholomew's Hospital; Cyril William Jenner, London Hospital and private study; George Basil Henley Jones, Guy's Hospital; William Henry Talfourd Jones, Guy's Hospital and private study; George Arthur Edward Kelman, King's College and Westminster Hospital, Harold Drew Lander, Cambridge University and St. Bartholomew's Hospital; Lewis Francis Gurslave Lewis, B.A. Cantab., Cambridge University and St. Bartholomew's Hospital; Charles Erie Lowe, Westminster Hospital; Victor Alfred Lunn, Guy's Hospital; Avenel Frederick Cleeve Martyn, St. Mary's Hospital; Marwood Mintern Munden and Wilfred Guy Stuart Neely, Guy's Hospital; Richard James Paget, Middlesex Hospital; Charles Edward Hewitt Paley, Westminster Hospital; Hubert Charles George Pedler, University College Hospital; Montague Pern, Guy's Hospital; Oswald Pitt, Manchester University; Alfred Henry Richardson, M.A. Cantab., Cambridge University and St. Thomas's Hospital; George Holmes Smith, L.D.S. Eng., St. Mary's Hospital; Patrick Arthur Sullivan, Birmingham University; Frederic Charles Victor Thompson, Guy's Hospital; Daniel Owen Twining, University College Hospital; Richard Herbert Vercoe, B.A. Cantab., Cambridge University and University College Hospital; Ronald Herbert Vicary, St. Mary's Hospital; and George Ernest Vilvandré, Claude Bedford Welsby, and Hugh Wetherbee, London Hospital.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Preliminary Science Examination for the Licence in Dental Surgery held this month the following gentlemen were approved in the undermentioned subjects:—

Chemistry and Physics.—Walter Frederic Edgar Badcock, High School, Middlesbrough; Horace Edgar Bampton and Robert Leslie Booth, Birmingham University; William Allen Bulleid, Guy's Hospital; Walter Tyrrell Cooper, University College, Cardiff; Cyril Lister Curle, Birmingham University; Harry Drake, Leeds University; Will Smith Harris, Technical College, Bradford; Sydney Nuttall Hayes, Technical School, Manchester; Llewelyn Gwynne Hopkins, University College, Cardiff; Arthur James Horniblow, University College, Reading; Bertrand Kemp Jackson, High School, Middlesbrough, and Harris Institute, Preston; William Sanders Johnstone, Charing Cross Hospital; Ewart McArd, Middlesex Hospital; Frederic Humble Morrell, High School, Middlesbrough; Raphael

Neft, Darmstadt University; Winifred Amelia Oaten, London School of Medicine for Women; Gustavus Leigh Pemberton, Battersea Polytechnic; Thomas William Stark, University College, Nottingham; Donald Thorne, University College, Exeter; Thomas Bernice Tustian and Percy James Wakley, University College, Cardiff; and Frank Roland Wallis and Frank Wisher, Guy's Hospital.

Chemistry.—Percy Ashton, Birmingham University; Alan Strafford Clarke, M.A. Cantab., Birkbeck College; Herbert Howard Cooke, Cardiff and Technical Institute, Wandsworth; Thomas Clement Davies, Charing Cross Hospital; Percy Scott McFarlane, Birkbeck College; Charles Wyndham Martin, Liverpool University; Benjamin Micklethwait, Birkbeck College; Arthur Pomroy Sainsbury, Polytechnic Institute; and Edward Royston Saul, Guy's Hospital.

Physics.—William Francis Gawne, Technical School, Liverpool; William John O'Kane, Guy's Hospital; Robert William Spong, Municipal College, Portsmouth; John Alphonsus Tighe, Technical Institute, Wandsworth; Samuel Lloyd Wallis, Birkbeck College; and Lewis William Wilson, Charing Cross Hospital and Technical Institute, Wandsworth.

UNIVERSITY OF LONDON.—At the Second Examination for Medical Degrees, Part I., the following candidates were successful:—

Organic and Applied Chemistry.—W. P. Charles Abeyedeera, University College; Elizabeth Labrey Ashby, University and Municipal Technical School, Birmingham; Guido Carlo Giulio Baldini, St. Bartholomew's Hospital; Frank Montague Barnes, St. Thomas's Hospital; William Claude P. Barrett, University College; Irene Bastow, London (Royal Free Hospital) School of Medicine for Women; Frederic Vivian Bevan-Brown, Guy's Hospital; Marjorie Ada Blandy, London (Royal Free Hospital) School of Medicine for Women; John Bostock, London Hospital; Alice Dorothea Brooks, London (Royal Free Hospital) School of Medicine for Women; Frederick Charles S. Broome, Guy's Hospital; William Burt and Harold Garrett Chaplin, St. Thomas's Hospital; Raymond John Clausen, University College; Aaron Simeon Cohen, University College, Cardiff; Dora Challis Colebrook, London (Royal Free Hospital) School of Medicine for Women; Frank Collar, Guy's Hospital; John Kenyon Davies and Percy Vernon Davies, University College, Cardiff; William Llewellyn G. Davies, Guy's Hospital; William Thomas Davies, London Hospital, University Tutorial College, and private study; Frederick Henry Dodd, Guy's Hospital; Arthur Rawdon C. Doorly, St. Thomas's Hospital; Cyril Henry Edwards, Birkbeck College and private study; Ahmed Fahmi El-Hakim, London Hospital; Pattie Ruth Elliott, London (Royal Free Hospital) School of Medicine for Women; Robert Ellis, University and Municipal Technical School, Birmingham; Philip Oswald Ellison, St. Bartholomew's Hospital; Henry William Evans, Guy's Hospital; Julian Trevor Eyre Evans, St. Mary's Hospital; Hugh James Orr Ewing, University of Bristol; George Finch, University College; Septimus Alexander Forbes, London Hospital; Humphrey Leonard George Foxell, University College; Charles Hamilton Gould,* Guy's Hospital; Frank Arthur Grange, London Hospital; Malcolm Gross, King's College and Westminster Hospital; Charles Frederick Hacker,* King's College; Allen Coulter Hancock, Guy's Hospital; Mary Esther Harding, London (Royal Free Hospital) School of Medicine for Women; Daniel Thomas Harris, private study; John Richard Harris and Claude Charles Harrison, University of Bristol; Stanley Sextus B. Harrison,* Guy's Hospital; Henry Julyan Hoyte, King's College; Charles Evans Jenkins, University College, Cardiff; Rosalie Jobson, London (Royal Free Hospital) School of Medicine for Women; Stanley Burrough King, St. Mary's Hospital; Leslie Mordaunt Ladell, London Hospital; Kingsley Wassell Lewis, University College, Cardiff; Iorwerth H. Lloyd-Williams, University Tutorial College; Norman Peace Lacy Lumb, St. Thomas's Hospital; Ronald Guy Lyster, St. Bartholomew's Hospital; Fede Margherita Mackenzie,* London (Royal Free Hospital) School of Medicine for Women; Desmond Manus MacManus, Guy's Hospital; Edith Marjorie Martland, London (Royal Free Hospital) School of Medicine for Women; Jivraj Narayan Mehta, Grant Medical College, Bombay, and London Hospital; Allan Noel Minns and James York Moore, Guy's Hospital; Henry Ray Parsloe, London Hospital; Purushottam Tulsibhai Patel, Grant Medical College, Bombay, and London Hospital; Julian Lionel Priston, London Hospital; James Albert Robinson and William Eric Roper Saunders, St. Bartholomew's Hospital; Gerald Davenant Shann, King's College; Henry Richard Sheppard, Brighton Municipal Technical College; Ronald Silcock, St. Mary's Hospital; Reginald Hugh Simpson, St. Bartholomew's Hospital; John Smith Sloper, St. Thomas's Hospital; Leslie Muir Smith, Guy's Hospital; Francis Gerald Augustus Smyth, St. Bartholomew's Hospital; Trevor Richard Snelling, London Hospital; Edward Sequier Sowerby, University of Bristol; Clifford William Sparks, St. Thomas's Hospital; John Eric Stacey, University of Sheffield; Grace Stapleton, London (Royal Free Hospital) School of Medicine for Women; John Stephenson, Guy's Hospital; William Edmund Taylor, University of Bristol; Naomi Tribe, London (Royal Free Hospital) School of Medicine for Women; Ernest Haines Walker, St. Thomas's Hospital; Herald Joseph Wallace and John Glen Wardrop, University College; George Nesbit Welsford, University of Bristol; Gerald Richard Courtenay Wilson, St. Thomas's Hospital; Arthur Graham Winter and Herbert Gregory Winter, London Hospital; and Douglas H. David Wooderson, St. Bartholomew's Hospital.

* Awarded a mark of distinction.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

PRIMARY EXAMINATION, PART I.

Biology.—R. W. L. Oke, London Hospital.

Chemistry.—A. U. L. Bennet, Royal Free Hospital.

Materia Medica and Pharmacy.—H. H. Gunnell, Guy's Hospital; A. R. Jennings, Cambridge; L. E. Lewis, Cardiff; and O. Marshall, University College Hospital.

PART II.

Anatomy.—R. B. F. Frazer, Charing Cross Hospital; A. Griffith-Williams, Cambridge and London Hospital; K. L. Hart-Davis, Royal Free Hospital; and D. Havard, L. M. Ladell, and G. A. Walker, London Hospital.

Physiology.—F. S. Charnock, Manchester; P. R. Cross, St. Mary's Hospital; G. E. Cuttle, Manchester; R. B. F. Frazer, Charing Cross Hospital; A. Griffith-Williams, Cambridge and London Hospital; K. L. Hart-Davis, Royal Free Hospital; and D. Havard, L. M. Ladell, and G. A. Walker, London Hospital.

LONDON SCHOOL OF TROPICAL MEDICINE.—The following students have successfully passed the examination held at the end of the thirty-second session, January to April:—

T. B. Adam (Colonial Service), R. Blue (United States Public Health and Marine Hospital Service), *G. D. H. Carpenter (Colonial Service), E. A. S. Carrington, *P. Harper (Colonial Service), W. Kelly, C. G. Kurien, *J. C. McPherson (Colonial Service), *W. Morrison (Colonial Service), A. Onsy, E. D. Shroff, B. R. Vickers, and G. Wilson (Colonial Service).

* Passed with distinction.

FOREIGN UNIVERSITY INTELLIGENCE.—*Berlin:* Professor Waldeyer, the Director of the University Anatomical Institute, who is 73 years of age, intends to retire at the close of the ensuing summer session. The title of Professor has been conferred upon Dr. Johannes Herzog, *privat-docent* of Ophthalmology, and also on Dr. Gonzer, General Secretary of the Temperance Society.—*Bonn:* The charge of the Physiological Institute, vacant by the death of Professor Pflüger, has been taken over temporarily during the vacancy by his first assistant, Professor Schöndorff.—*Heidelberg:* Dr. J. Hoffmann, Extraordinary Professor of Medicine, has been appointed Honorary Ordinary Professor.—*Prague (German University):* Dr. Julius Rihl has been recognised as *privat-docent* of General and Experimental Pathology.—*Vienna:* Dr. Otto Kahler has been recognised as *privat-docent* of Otology and Rhinology.

THE ROYAL SANITARY INSTITUTE.—A provincial sessional meeting of the Royal Sanitary Institute will be held at Leicester on April 22nd and 23rd. On the first-named date, at 7 P.M., in the council chamber of the town-hall, Mr. E. G. Mawbey, M.Inst.C.E., will open a discussion on "Purification of Leicester Sewage, &c.," Mr. H. D. Searles-Wood being in the chair. Among those who are announced to take part in the discussion are Dr. A. Bostock Hill and Dr. George Reid. On April 23rd visits will be made to the Abbey Sewage Pumping Station and to the new bacterial works and broad irrigation at the Beaumont Leys Farm. Further particulars of the meeting may be obtained from Mr. Mawbey, the borough engineer and surveyor of Leicester, and from Mr. E. White Wallis, secretary of the Royal Sanitary Institute, 90, Buckingham Palace-road, London, S.W.

THE WINSLEY SANATORIUM NEAR BATH.—This institution, which was founded in 1904 by the Three Counties Branch of the National Association for the Prevention of Consumption for the poorer consumptives of Gloucester, Somerset, and Wilts, has just issued its annual report for the year 1909. The number of beds available in the sanatorium during the year was 68, 43 of which are maintained and 9 leased to various authorities. Of the remaining 16, 12 are reserved for patients at a payment of 15*s.* per week and 4 are utilised by the management for patients who pay 35*s.* to 42*s.* per week. The report of the medical officer, Dr. Leonard Crossley, shows that 248 patients were admitted during the year under notice and 236 discharged. Of these 111 left fit for work, 82 left improved, 37 left not improved, and 6 died in the sanatorium. An urgent appeal is issued by the board of management for increased support towards the reduction of the capital debt, which stands at over £9000.

THE ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW.—The annual report of the directors of the Royal Hospital for Sick Children, Glasgow, clearly shows the urgent needs, to meet which the board is appealing for funds. Some £94,000 have already been subscribed, but there is still a balance of £26,000 to be made up. During the year 1909 1012 patients were treated. Of these cases 493 were medical and 519 surgical. Of the total cases admitted 146 were infants under one year of age, and 150 were over one year and under two years of age. The average daily number under treatment in the hospital was

70. At the country branch of the institution, Drunchapel, 87 patients were treated. The ordinary income of the hospital was £7387 12*s.* 3*d.*, and the expenditure £7627 14*s.* 2*d.*, leaving a deficiency of £240 1*s.* 11*d.*

A CHURCH LADS' BRIGADE MEDICAL CORPS.—The formation of a medical corps in connexion with the Church Lads' Brigade is an important innovation. A corps of this kind has just been established at Brighton, with Surgeon-Major H. G. Hilbers as commanding officer. The lads are thoroughly interested in the work. Recently at field practice they showed three distinct kinds of work—first-aid treatment to lines of casualties, transit of wounded, and arrival at the collecting station. Demonstrations were also given in lifting unconscious patients by the fireman's lift, of artificial respiration, and of treatment for shock.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Deaths from Privation in 1908.

THE return has been published "of the number of deaths in England and Wales in the year 1908 upon which a coroner's jury has returned a verdict of death from starvation or death accelerated by privation, together with any observations furnished to the Local Government Board by boards of guardians with reference to cases included in the return.' The return includes 125 deaths, of which 52 occurred in the administrative county of London and 73 in the provinces. In two cases the jury returned a verdict that the death was due solely to "starvation." In 11 cases death was ascribed to starvation in conjunction with some other cause—e.g., disease, drink, exposure, or self-neglect. For the most part the deaths appear to have been due to disease consequent upon or accelerated by want or exposure, or both, or to self-neglect. In several cases death was due to causes unconnected with destitution. In 80 of the 125 cases no application had been made for poor relief or application was only made when the deceased was in a dying condition.

Poor-law Reform.

The debate in the House of Commons on the Prevention of Destitution Bill on Friday, April 8th, resolved itself into a discussion on Poor-law reform. The Bill embodies the recommendations of the Minority Report of the Royal Commission on the Poor-laws and was brought forward by Sir R. PRICE with the object of instituting a debate on these questions rather than as an attempt at immediate legislation. What was notable about the occasion was the earnestness and the non-party character of the speeches. Particular attention was given to the tone of Mr. BALFOUR'S speech, in which he emphasised the points of agreement rather than the points of difference which emerged in the course of the Royal Commission's inquiry. He urged also on Members on both sides the expediency of not allowing themselves to be dragged into controversy as between the two reports. Mr. ASQUITH entered fully into the spirit of the remarks of the Leader of the Opposition. In the present state of politics there is little chance of the Government introducing legislation in the immediate future to deal with the problems presented in the reports of the Royal Commission. The Prime Minister's concluding sentence, however, embodies the intentions of the present Government. "So far as I know the temper of the House of Commons," he said, "the moment we are able to address ourselves with free hands and full opportunity to the solution of the urgent problems which remain unsolved. I believe we shall carry with us, not the support of this party or of that, but the practically unanimous support and sympathy of the nation as a whole."

The Protection of Water-Supplies.

A joint committee of both Houses of Parliament is being appointed to consider the protection of water-supplies.

Sewage Disposal.

An appendix containing memoranda on special investigations and experiments has just been published to the fifth report of the Royal Commission on Sewage Disposal.

Milk-Supply.

Disappointment is expressed in many directions in the House of Commons that no general legislation dealing with milk-supplies is to be brought forward by the Government this session. Mr. BURNS is not inclined to re-introduce his Milk Bill of last year. His reason is that in the present state of political controversy it would be quite impossible to make progress with it. That is equally true of other departmental Bills. At the same time it is quite evident from the trend of the debate on the milk-supply clauses of the London County Council (General Powers) Bill that a very large section of the House of Commons views with disfavour the granting of fresh powers to individual local authorities in lieu of general legislation. This section, which protested against what is called "piecemeal legislation," was numerous enough to secure the deletion of the milk clauses which the London County Council desired. However, it was noticeable that many who voted against those clauses spoke in favour of general legislation on the subject. Some private Members intend, if they can obtain an opportunity, to urge further considerations on the Government to reintroduce the Milk Bill. Mr. COURTHOPE did in fact on Wednesday, April 13th, bring in a Bill "to make better provision with respect to the sale of milk and the regulation of dairies." It was read a first time. It is understood that its terms in some respects approximate to those of Mr. BURNS'S Bill of last year.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 6TH.

The Dairies, Cowsheds, and Milkshops Order (Ireland).

Mr. KERR-SMILEY asked the Chief Secretary to the Lord Lieutenant of Ireland whether he would state what was the total annual cost of administering the Dairies, Cowsheds, and Milkshops Order in the county of Antrim, and was any part of this expenditure paid out of the Imperial Exchequer.—Mr. BIRRELL replied: I am informed by the Local Government Board that the cost of administering the Order in county Antrim amounts, so far as fixed salaries of inspecting and registering officers are concerned, to £701 per annum. This does not include the remuneration of a few inspecting officers, who are paid by fees or incidental expenses. Half the salary of each veterinary inspector might be recouped from the Local Taxation account, provided there was an available margin, having regard to the limitation imposed by Section 6 of the Local Government (Ireland) Act, 1902. This restriction, however, is operative in all the sanitary districts in the county except Ballycastle rural district and Carrickfergus urban district, where there are credit balances of a trifling amount.

THURSDAY, APRIL 7TH.

Milk Legislation.

Mr. CHARLES BATHURST asked the President of the Local Government Board whether, in order to check the continued promotion by some urban local authorities of piecemeal legislation affecting the production and distribution of milk, he would introduce in the course of this session a Bill of universal application which would secure uniformity of administration on the part of all such authorities.—Mr. BURNS wrote in reply: I am afraid that in the present circumstances I cannot contemplate a general Bill on the subject of milk.

The Royal Commission on Tuberculosis.

Mr. CHARLES BATHURST asked the President of the Local Government Board whether the Royal Commission on Human and Animal Tuberculosis, which was appointed on August 31st, 1901, was still pursuing its investigations in reference to the communicability of bovine tuberculosis to human beings, and, if so, whether, in view of the urgent importance of the questions referred to the Commission, especially in their bearing upon the production and distribution of milk and of the fact that no report of the Commission had been issued since the third interim report of January, 1909, he would urge the Commission to present a fourth interim or a final report with as little delay as possible.—Mr. BURNS (in a written answer) replied: I understand that it is not the intention of the Commission to issue any further interim report, but the members are now engaged in considering the results of the experimental investigations and drafting the final report, and it is hoped that they may be able to present this in the course of a few months.

The Notification of Births Act in Scotland.

Mr. VIVIAN asked the Lord Advocate whether he would state how many local authorities had adopted the Notification of Births Act in Scotland, the names of such local authorities, and what diminution in the infant death-rate under one year had taken place.—Mr. URE replied (by written answer): I am informed that 23 local authorities in Scotland have already adopted the Act referred to, while four have resolved to do so this year. The infantile mortality rate depends so much upon the yearly weather conditions and the incidence of epidemic disease that it is not as yet considered safe to base upon its variations any inference as to the effect of the Notification of Births Act. The names of the local authorities are as follows, the four in which the Act is to become operative this year being marked with an asterisk. Burghs: Edinburgh, Glasgow, Stirling, Paisley, Greenock, Partick, Renfrew, Leith, Falkirk, Kilmarnock, Dundee, Govan, Kirkcaldy, Musselburgh, Irvine, Hamilton, Motherwell, Port Glasgow, Aberdeen, Pollokshaws, *Inverness, and *Ayr. County districts: Kirkcaldy district of Fife, Lower Ward district of Lanark, Upper district of Renfrew, *Middle Ward district of Lanark, and *Dunfermline district of Fife.

The Milk-supply in London.

The London County Council (General Powers) Bill was on the notice paper for second reading. Part VI. contained provisions for dealing with the milk-supply.

On the motion for the second reading of the Bill,

Mr. COURTHOPE moved its rejection as an amendment. He said that this was the third year in succession in which he had had to oppose a Bill of the London County Council on behalf of the agricultural bodies of the country. The ground of his opposition was based on the attempt to continue an obnoxious and admittedly defective system of piecemeal legislation with regard to milk-supply. He was fully aware that the agricultural opposition was only directed to Part VI. of the Bill, and he was perfectly willing, if the representatives of the London County Council would indicate their willingness to accept a subsequent motion of his to instruct the Select Committee to delete Part VI., to withdraw his opposition to the Bill. He admitted that milk legislation was necessary, but his objection was to the piecemeal proposals of the Bill. He would point out two or three defects in the milk-supply clauses of the Bill. In Clause 33, for instance, the London County Council took powers to take samples of milk *in transitu* at any time practically till it reached either the place where it was retailed or the place where it was supplied for human consumption. Up to that moment the London County Council proposed to place the whole responsibility for

any contamination in handling in transit on the dairy farmer or producer. There were many cases which could be cited in which the dairy farmer had transmitted the milk to London and it had been adulterated after it had left his hands, and so long as that policy was adopted, so long would the sense of injustice remain in the minds of the dairy farmers, and strenuous opposition would be offered to proposals of that kind. Then came other clauses to which he and his friends objected. They were Clauses 37 and 42, under which the Council sought to take extraordinary powers outside its jurisdiction for its inspectors, medical officers, and veterinary officials which gave rise to great inconvenience without being effective for the purpose of protecting the consumer. These clauses were not the only provision which London had for the protection of its milk-supply. It had already got in one of its Acts what were known as the model milk clauses, which were, so long as this piecemeal legislation went on, the only possible basis of agreement and convenient legislation which one could devise, although he admitted that they were imperfect. The only other point of importance contained in these new clauses was with reference to tuberculosis. There were provisions which were based on the third interim report of the Tuberculosis Commission. They were to include powers to deal with tuberculosis and with emaciation, as the Bill stated, and also with cows which gave tuberculous milk, in addition to the powers already possessed to deal with tuberculosis of the udder. He had no particular fault to find with the proposals made with these two additions as far as they went, but the chief ground of objection was the objection upon principle to piecemeal legislation. He asked the President of the Local Government Board to bear in mind that by the Bill of the London County Council hardship would be inflicted on the poorer communities by unloading on them milk which London would not accept. He expressed an opinion that the Milk Bill as introduced by the Government last year could easily have been passed during the evenings which were wasted before Easter.

Mr. STANIER seconded the amendment.

Mr. WALTER GUINNESS, who spoke on behalf of the London County Council, said that that body would have preferred general legislation. The Milk Bill introduced last year would have done all that was required. He fully recognised that the effect of the milk-supply clauses in the London County Council Bill would, whilst keeping milk of an inferior quality out of London, not prevent it being sold in other localities. That undoubtedly was an evil, but London was specially in need of legislation because a very large proportion of its milk-supply came from a considerable distance, and polluted milk was far less injurious if drunk fresh before the bacilli had time to breed than if drunk even 24 hours or two days later, when the microbes had had time to propagate. For that reason London had a right to be considered perhaps before any other part of the country. He went on to point out that in 1907 a penalty was placed in London on the sale of tubercular milk of cows with tuberculous udder. In the two years in which that provision had been in force a considerable improvement had taken place and farmers had taken care not to sell milk from cows with a tuberculous udder. Since then information had come to light showing that the tuberculous udder was not the only form of disease from which infection might take place The third interim report of the Royal Commission on Tuberculosis showed that any form of tuberculosis in cattle was liable to infect milk. London, he went on to say, had been the dumping ground of all the dirty milk in the country. Where a large town was in the centre of an agricultural district the agriculturist whose cowsheds were not in good order did not attempt to send his milk to that town. He sent it all to London. That was what the London County Council wished to stop. No doubt a certain amount of dirt was added locally, and powers were taken in the Bill to enable borough councils to prosecute in those cases. The dirt which was added locally on the farm could very well be distinguished from the dirt which came in on the railway. If it was found from a microscopical examination that there were farm products in the milk, it was not to be imagined that they came from the railway. If smuts or tea-leaves were found in the milk, as it was said owing to the railway porters dipping their tea-tins in the milk, no one could accuse the farmers of being responsible. It would be quite obviously railway dirt added in transit. The London County Council proposed under the Bill to take samples of milk at the railway stations and where they found gross and unnecessary negligence to inspect the farms. It was said that this was a very dangerous provision which would lead to a great deal of inconvenience on the farm, but this power was possessed at present for tuberculosis, and the London County Council could have any farm inspected where it was found that milk with tuberculosis bacilli was sent to London. The clause of the Bill only copied the provision which was actually embodied in the Milk Bill of last year. The Council was perfectly ready to withdraw its milk-supply clauses if an assurance was given that the Government really intended to pass a general Milk Bill into law.

Mr. EMMOTT, Chairman of Ways and Means, asked the House to pass the second reading and to take the division with regard to the milk-supply on the motion that it should be an instruction to the Select Committee to delete from the Bill the clauses relating to this subject.

Mr. COURTHOPE assented to this course.

The Bill was read a second time without a division.

Mr. COURTHOPE then moved "that it be an instruction to the Committee to delete Part VI. (Milk-supply)."

Mr. JAMES MASON expressed sympathy with the general objects of Part VI., but urged that anything in the shape of piecemeal legislation might materially tend to injure the interests of the consumer of milk. He was convinced that tuberculosis could be eventually stamped out, and pure milk could be got if people were willing to pay a higher price.

Mr. BURNS (President of the Local Government Board) said that the honourable Member for Bury St. Edmunds (Mr. Guinness), in his opinion, had convinced the House that legislation was necessary to enable London to deal not only with the purity of the milk-supply but to deal with tuberculous milk, whether it was drawn from cows with tuberculous udders or cows suffering from tuberculous emaciation. In fact, no one had challenged the case made out for the County Council by the honourable Member as to the necessity for legislation. The honourable Member who had just spoken (Mr. Mason) had drawn from his own experience conclusive proof that given certain conditions tuberculosis could be stamped out not only in animals but in human beings. That was a question to which, to the credit of the nation, increasing attention was being devoted. He ventured to say that tuberculosis in this country among human beings would in time be almost as scarce as typhus and typhoid now were. The disagreement between the honourable Member for Rye (Mr. Courthope) and himself arose over other points and they were very small in number. The honourable Member, ardent champion as he was of the agricultural interest, admitted that it was disadvantageous to the farming interest as a whole that it should be connected too closely with the defence of those conditions which prevented London, which was the best milk-consuming customer of the dairying trade, getting better and cleaner milk. In his opinion London ought to have twice the amount of milk it now had. The honourable Member for Rye said that he regarded it as a serious condition of things that the London County Council should have power to take samples of milk in transit. He did not regard it at all as outrageous. He would give the honourable Member a simple fact. A very ingenious statistical friend of his had calculated that the total milk-supply that came into London for a whole year was equal under normal conditions to the daily flow of the River Thames over Teddington Weir. That gave an indication of the amount of milk brought into London. Surely, therefore, if that was the extent of the trade problem with which they had to deal there ought to be no objection to a medical officer of health being empowered to take steps to see that the people who were to consume the milk should not run risks in the way of infection, and that he should be allowed to go to the other side of Teddington Weir and take a few samples in order to ascertain whether it came from cows with tuberculous udders or from cows suffering from tuberculous emaciation. In this matter they had precedent to guide them. Cities like Manchester and Leeds had not only the advantage of the model clauses, but they had the advantage of special local Acts, giving them the powers which the London County Council was now seeking. The effect was that farmers knowing that these powers existed in these cities and elsewhere no longer sent in either impure or tuberculous milk. Their cowhouses were so constructed and arranged as to give the most beneficial results to the consumers and the farmers as a whole. The honourable Member for Rye asked whether the farmer was to be saddled with responsibility for dirt added in course of transit. He would like to point out to the honourable Member that he only wished to put the farmer right in this matter. Might he say personally and as a Cabinet Minister that this was a very serious matter? In some respects it was a delicate question. It was one in which very often the farmer ought to have the benefit of the doubt because he was placed in a more difficult situation in reaching his customer than was the man who sold potatoes or turnips or meat, that were not so liable to infection of all kinds as was milk, which, while it was one of the most nutritious of foods, especially for children, was, oddly enough, the most susceptible of all forms of contagion. All Ministers and all local authorities were willing to look at the farmer from that point of view. The only other point which the honourable Member made was this. He said that this matter ought not to be treated in a piecemeal way. Ideally and theoretically, all would agree with him. If it were in France or in Germany, and in other countries where things were logically done, the question might be treated in a comprehensive fashion, but in this country things were done by instalments and compromise. Why did the honourable gentleman object to the process of instalment and compromise in legislation on an important subject like this? The honourable Member knew full well that everything which he (Mr. Burns) could do a year ago to bring in a large Milk Bill he did, and the farmers were kind enough to say that they were pleased with the attitude of the Local Government Board in regard to their trade and industry. He believed that any assurance which he could now give in regard to further action in reference to this industry would be readily received, but the honourable Member for Rye knew very well that a Milk Bill could not be got through last year because other questions took up time which he (Mr. Burns) hoped might have been partially given to a Milk Bill. The honourable Member also knew full well that if this was true of last session, it was equally true of this session. The fact was that the House on both sides was extremely anxious that the Government should keep to the main issues of this session. To suggest to the House that such a Bill could be got through this year was to whisper a promise to the ear only and to break it to the hope. He would not do that, even though it might be pleasant to the honourable Member for Rye. When the honourable Member suggested to the House that the differences on the Milk Bill were very small, he would point out to him that though this appeared to be small it was really a difficult matter to settle. There were questions relating to land and agriculture, and there was the question of whether compensation for slaughtered animals should come out of the local rates or the Imperial taxes. The honourable gentleman knew very well that this was a most thorny and contentious subject. There was this and many other aspects in connexion with the land and agricultural problem which entered into this discussion, and it was no good to try and persuade the House that the matter was not contentious or that agreement could be reached upon it in a few minutes. He was positively convinced that could not be done. But on the point which divided the various parties there was no reason for this subject being mentioned at all. Compensation for the slaughter of animals did not come into the London County Council Bill, and therefore the difference which divided them on a general Milk Bill did not come up for consideration now. The honourable Member for Bury St. Edmunds had told them the history of this subject and how London had waited not only for ten years but for longer than ten years. He had told them that model clauses were enjoyed in the provinces before London had an opportunity of receiving them, but he also told them that apart from tuberculosis in milk they had no right to allow dirty milk to come into London as it now did. That, however, was provided for in a simple way. Borough councils had power to deal with dirty milk and they would do it, he was sure, reasonably and fairly, while the London County Council would have power within the County of London to deal with tuberculous milk on evidence produced and cause shown, and also to deal with milk from cows suffering from tuberculous emaciation, besides power to deal with cows in the country outside the jurisdiction of the Council suffering from tuberculosis. Might he put this to honourable Members representing agricultural constituencies? Were they wise in the interests of the farmers and of agriculture in creating the impression throughout the country that it was to the interest of the farmer and the agriculturist that in London where dirty

and diseased milk could be sold that such a condition of things ought to be allowed to remain? The inference London people would draw from that was that the farmers must have some reason for countenancing that condition of things going on. If the confidence of people were shaken in any article of diet like milk, the tendency was that the demand and consumption of it would be diminished. It seemed to him in the best interests of the farmers that they should see to what their customers wanted—namely, that milk was not diseased and that it was produced under clean conditions. If they did so the milk trade would prosper. By the provisions in the Bill the County Council was demanding that the farmers should give better and cleaner milk to the Londoners than they did now. That would give to the farmer more profit and a larger industry. The Local Government Board and the London County Council officers would do their best to extend the industry, and would do nothing either to irritate or to prejudice the farming and dairying industry, which all of them would like to see developed more rapidly than it was now doing. It could best develop with the best sanitary conditions imposed upon it reasonably and fairly by the London County Council.

Mr. WALTER LONG criticised the action of the Government in delaying general milk legislation. The whole responsibility for inaction rested with the Government. Many who were prepared to support these clauses thought that there was much in them objectionable. It was highly objectionable that they should be passed in this special form and not in a Bill applying to the whole country. Yet honourable Members were face to face with the situation. The Government declined to attempt to carry general legislation. They said that they would, only there was more pressing work to do. Therefore, unless they supported the London County Council with this separate legislation nothing would be done until the present Government had been replaced by another for probably two or three years. Under these circumstances there could be no choice for him. He was not sure that there was not a good deal to be said against the actual procedure adopted in order to enforce this farm sanitation. Under all the circumstances, realising as he did that there was a necessity for increased inspection in this particular article of food, he for one should certainly support the Bill of the London County Council. He should do so solely because the Government were unwilling to give the House the legislation which ought to be given, and because he thought it was necessary that London at least, the greatest urban community in the country, should have that protection which many parts of the country needed.

Colonel LOCKWOOD said that he had every wish to assist the Government in ensuring that milk was sold pure, but he strongly objected to piecemeal legislation and to a series of regulations which were not uniform in their operation all over the country.

On a division there voted for the motion, 85; against, 81; majority for the motion, 4. It was therefore ordered that it should be an instruction to the committee on the Bill to delete Part VI. (Milk-supply).

MONDAY, APRIL 11TH.

Mortality in a Mining Centre.

Mr. STEEL-MAITLAND asked the Secretary of State for the Home Department how many deaths from pneumonoconiosis, bronchitis, and other lung diseases respectively, had occurred in each of the years 1907, 1908, and 1909 in those enumeration districts in the valley of the Don above Sheffield in which ganister mines were situated; what rates those deaths formed of the population of those districts, and how they compared with the rates of mortality from similar diseases for England as a whole; and what would be the mortality figure for those districts from those diseases if calculated on the lines of Table IV., Vol. II., of the last Decennial Supplement to the Report of the Registrar-General.—Mr. CHURCHILL answered: I have communicated with the Registrar-General, who states that causes of death are not classified for areas less than the registration districts, and that while it would be possible to furnish death-rates for the diseases mentioned in the district principally affected during 1909 and 1908, the effect of any special mortality amongst miners would be masked by the general mortality of the district, and that the rates themselves could not be taken as reliable in view of the time that has elapsed since the last census. This would also prevent any mortality figure being prepared. I think the best course will be to leave the matter to the Royal Commission on Mines which will be making inquiry into the working of the special rules for rock-drilling, and will doubtless consider what statistics can be obtained. I may add that the inspector informs me that there is far less dust and ventilation is much better now in these mines, and that workers and officials are agreed that the effect of the special rules has been most beneficial.

Mediterranean Fever.

Mr. ROBERTSON asked the Under Secretary of State for the Colonies whether the Government was about to send another Commission to Malta to investigate further the question of Mediterranean fever; and, if so, what was to be the composition of such Commission; and whether, in view of the fact that the conclusions of the last Mediterranean Fever Commission had been gravely called in question, steps would be taken to ensure that one or more unprejudiced persons would be included in the new Commission, who would be competent and willing to take into serious consideration the sanitary conditions of the island and of the quarters provided for the garrison, and their bearing upon the question of Maltese fevers.—Colonel SEELY said in reply: The question of appointing another Commission to inquire into Mediterranean fever is under consideration; but the only question which appears to require further investigation is the manner in which goats, which have been shown to be the main, if not the only, source of the disease in man, become themselves infected. It will not, therefore, in the opinion of the Secretary of State, be either necessary or desirable to include within the scope of the Commission the matters referred to by my honourable friend.

TUESDAY, APRIL 12TH.

Experiments on Living Animals.

Sir FRANCIS CHANNING asked the Secretary of State for the Home Department whether he would state when the returns of experiments on living animals for 1909 would be issued, and whether he would expedite them.—Mr. CHURCHILL wrote in reply: The returns will, I trust, be issued in June as usual. I am sorry that I do not see my way to expedite the matter.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

BOYLAN, D., M.B., B.S. R.U.I., has been appointed Certifying Surgeon under the Factory and Workshop Act for the Ballycastle District of the county of Antrim.

BRAITHWAITE, L. R., F.R.C.S. Eng., has been appointed Assistant Surgeon to the Leeds General Infirmary.

COUPLAND, J. A., F.R.C.S. Eng., has been appointed Assistant Surgeon to the General Infirmary, Leeds.

HALE, R. E. V., M.R.C.S., L.R.C.P. Lond., has been appointed Anæsthetist to the Samaritan Free Hospital for Women.

HANDFIELD-JONES, R., M.D. Durh., M.R.C.S., L.R.C.P. Lond., L.S.A., has been appointed Honorary Physician to the Warneford, Leamington, and South Warwickshire Hospital.

HAYES, G. CONSTABLE, F.R.C.S. Eng., has been appointed Surgeon with charge of the Ophthalmic Out-patients at the General Infirmary, Leeds.

NEWHAM, H. BASIL, M.R.C.S., L.R.C.P. Lond., D.P.H. Camb., D.T.M. & H. Camb., has been appointed Director of the London School of Tropical Medicine.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

BANBURY, HORTON INFIRMARY.—House Surgeon. Salary £80 per annum, with board and residence.

BARNSLEY, BECKETT HOSPITAL.—Junior House Surgeon. Salary £80 per annum, with board, residence, and laundry.

BELGRAVE HOSPITAL FOR CHILDREN, Clapham-road, S.W.—Assistant Surgeon.

BOLINGBROKE HOSPITAL, Wandsworth Common, S.W.—Two House Surgeons for six months. Salary at rate of £75 per annum, with board and residence.

BRISTOL ROYAL HOSPITAL FOR SICK CHILDREN AND WOMEN.—Senior Resident Officer. Salary £100 per annum, with rooms and attendance.

BURY INFIRMARY.—Senior House Surgeon and Junior House Surgeon. Salary £110 and £80 per annum respectively, with board, residence, and laundry.

CANTERBURY, KENT AND CANTERBURY HOSPITAL.—House Surgeon, unmarried. Salary £80 per annum, with board, lodging, and washing.

CARDIFF, UNIVERSITY COLLEGE OF SOUTH WALES AND MONMOUTHSHIRE.—Lecturer in Histology and Embryology. Salary £200 per annum. Also Professor of Pathology and Bacteriology. Salary £450 per annum.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.—House Surgeon. Salary 40 guineas per annum.

CHELSEA HOSPITAL FOR WOMEN, Fulham-road, S.W.—Clinical Assistant.

CITY OF LONDON HOSPITAL FOR DISEASES OF THE CHEST, Victoria Park, E.—House Physician for six months. Salary at rate of £75 per annum, with board, washing, and residence. Also Clinical Assistant.

CROYDON GENERAL HOSPITAL.—Junior House Surgeon. Salary £60, with board, laundry, and residence.

DEVONPORT, ROYAL ALBERT HOSPITAL.—Assistant Resident Medical Officer, unmarried, for six months. Salary at rate of £50 a year, with board, apartments, and laundry.

DOUGLAS, NOBLE'S ISLE OF MAN GENERAL HOSPITAL AND DISPENSARY.—Resident House Surgeon, unmarried. Salary £90 per annum, with board and washing.

EASTERN DISPENSARY, Leman-street, E.—Resident Medical Officer. Salary £120 per annum, with residence and attendance.

ELHAM UNION.—Medical Officer. Salary £25 per annum, with vaccination fees about £35.

EVELINA HOSPITAL FOR SICK CHILDREN, Southwark Bridge-road, London, S.E.—House Surgeon for six months. Salary at rate of £60 per annum, with board, residence, and washing. Also Honorary Dental Surgeon.

FARNINGHAM AND SWANLEY, KENT, HOMES FOR LITTLE BOYS.—Medical Officer, unmarried. Salary £100 per annum, with board, residence, and laundry.

HEMEL HEMPSTEAD, WEST HERTS HOSPITAL. — House Surgeon. Salary £100 per annum, with rooms, board, and washing.

HEREFORD COUNTY AND CITY ASYLUM, Burghill, Hereford.—Junior Assistant Medical Officer, unmarried. Salary £120 per annum, with board, apartments, and laundry.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—House Physician for six months. Salary 30 guineas.

HOSPITAL FOR SICK CHILDREN, Great Ormond-street, London, W.C.—House Surgeon, unmarried, for six months. Salary £30, with board and residence. Also Casualty Medical Officer. Salary £200 per annum, with lunch.

HULL, ROYAL INFIRMARY.—House Physician, unmarried. Salary £100 per annum, with board and apartments.

JOHANNESBURG, TRANSVAAL, GOVERNMENT LABORATORIES.—Assistant Bacteriologist. Salary at rate of £450 per annum.

LEEDS GENERAL INFIRMARY.—Clinical Pathologist. Salary £300 per annum.

LEICESTER INFIRMARY.—House Physician. Salary at rate of £100 per annum, with board, apartments, and washing.

LEICESTER PARISH POOR-LAW INFIRMARY.—Second Resident Assistant Medical Officer. Salary £120 per annum, with rations, apartments, and washing.

LONDON LOCK HOSPITAL AND HOME, Harrow-road, W., and 91, Dean-street, W.—Surgeon.

MANCHESTER ROYAL INFIRMARY AND DISPENSARY.—Honorary Assistant Surgeon.

MIDDLESBROUGH, NORTH RIDING INFIRMARY. — Assistant House Surgeon. Salary £75 per annum, with residence, board, and washing.

MOUNT VERNON HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Hampstead and Northwood, Middlesex.—House Physician. Salary £75 per annum, with board and residence.

NATIONAL DENTAL HOSPITAL AND COLLEGE, Great Portland-street, W.—Assistant Dental Surgeon.

NEWCASTLE-ON-TYNE DISPENSARY.—Visiting Medical Assistant. Salary £160 per annum.

NORWICH, NORFOLK AND NORWICH HOSPITAL. — Assistant House Surgeon for six months. Salary £20, with board, lodging, and washing.

OLDHAM GENERAL INFIRMARY.—Senior House Surgeon. Salary £120 per annum. Also Second House Surgeon. Salary £100 per annum. Also Third House Surgeon. Salary £80 per annum. All for six months, with residence, board, and laundry.

PADDINGTON GREEN CHILDREN'S HOSPITAL, London, W. — House Physician and House Surgeon for six months. Salary at rate of 50 guineas per annum each, with board and residence.

PRINCE OF WALES'S GENERAL HOSPITAL, Tottenham, N.—House Surgeon, House Physician, Junior House Surgeon, and Junior House Physician. Salaries of two former £75 per annum, and of two latter £40 per annum, with residence, board, and laundry.

QUEEN CHARLOTTE'S LYING-IN HOSPITAL, Marylebone-road, N.W.—Assistant Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, residence, and washing.

READING, ROYAL BERKSHIRE HOSPITAL.—House Surgeon. Salary £80 per annum, with board, lodging, and washing. Also Second House Surgeon for six months. Salary £60 per annum, with board, lodging, and washing.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—Examiners under the Conjoint Examining Board in England. Also Examiners in Anatomy and Physiology for the Fellowship.

ROYAL LONDON OPHTHALMIC HOSPITAL, City-road, E.C.—Bacteriologist. Salary at rate of £120 per annum, with lunch.

ROYAL NAVAL MEDICAL SERVICE.—Examination for Fifteen Commissions.

RUTLAND COUNTY COUNCIL.—County Medical Officer of Health and County School Medical Officer. Combined salary £400 per annum.

SHEFFIELD ROYAL HOSPITAL.—Assistant House Physician, unmarried. Salary £50 per annum, with board, lodging, and washing.

SOUTHWARK UNION INFIRMARY, East Dulwich-grove, S.E.—Assistant Medical Officer. Salary £100 per annum, with board, lodging, and washing.

TUNBRIDGE WELLS GENERAL HOSPITAL.—Junior Resident Medical Officer. Salary £80 per annum, with board, residence, &c.

WARRINGTON, LANCASHIRE COUNTY ASYLUM, Winwick.—Locum Tenens Medical Officer, unmarried. Salary 4 guineas per week, with apartments, board, &c.

WESTERN SKIN HOSPITAL, 179, Great Portland-street, W.—Clinical Clerk.

WOLVERHAMPTON AND STAFFORDSHIRE GENERAL HOSPITAL.—House Surgeon. Salary at rate of £80 per annum, with board, rooms, and laundry.

YORK DISPENSARY.—Resident Medical Officer, unmarried. Salary £130 per annum, with board, lodging, and attendance.

THE Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies as Certifying Surgeons under the Factory and Workshop Act at Tarbert, in the county of Argyll; at Lisdoonvarna, in the county of Clare; at Limavady, in the county of Londonderry; at Carnmoney, in the county of Antrim; at Witney, in the county of Oxford; at Harris, in the county of Inverness; at Navan, in the county of Meath; at Insch, in the county of Aberdeen; and at Ballindalloch, in the county of Banff.

Births, Marriages, and Deaths.

BIRTHS.

CARVER.—On April 11th, at Higher Terrace, Torquay, the wife of A. E. Carver, M.D., of a daughter.

GLENNY.—On April 7th, at Effingham-road, Bristol, the wife of E. T. Glenny, M.B., B.S., of a daughter.

MARRIAGES.

ARMSTRONG—MACMIN.—On April 7th, at St. Pancras Parish Church, Arthur Keith Armstrong, M.R.C.S., L.R.C.P. Lond., of Monmouth, to Louise Lily, daughter of John Macmin, of Dartmouth Park-road, Highgate.

PARSONS-SMITH—BURNETT.—On April 9th, at St. Peter's Church, South Croydon, Basil Thomas Parsons-Smith, M.D., B.S. Lond., to Marguerite Ida, daughter of Sir David and Lady Burnett.

DEATHS.

GAMAN.—On April 9th, in London, Francis R. S. Gaman, M.R.C.S., L.R.C.P., of Caistor House, Caistor, Lincolnshire, aged 40 years.

PERKS.—On April 4th, Charles Perks, L.R.C.P., M.R.C.S., of Burton-on-Trent, aged 68 years.

N.B.—A fee of 5s. is charged for the Insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE CONSUMPTION OF ALCOHOLIC BEVERAGES.

Mr. G. B. Wilson, secretary of the United Kingdom Alliance, recently addressed a letter to the *Times*, estimating the total value of alcoholic beverages consumed in the United Kingdom in the year 1909. The uncertainty connected with the Budget was, of course, a considerable obstacle to the accurate estimation, but making such allowances as seem necessary, Mr. Wilson estimated the amount for 1909 at £155,162,485, as compared with £161,060,482 in 1908. His letter continued:—

> "There has, therefore, been a decrease in expenditure of £5,897,997. On spirits the decrease was £4,800,000 with a decrease in consumption of 7,022,775 gallons. On beer the decrease was £1,186,000, with a decrease in consumption of 645,396 barrels. On wines, on the other hand, there has been an increase of £93,000, with an increase in consumption of 103,744 gallons. If there had been no increase in prices, the reduction on the total expenditure would have been £11,147,997. In 1909 the average expenditure per head was £3 8*s.* 11½*d.* and per family of five persons £17 4*s.* 9½*d.*, compared with £3 12*s.* 3¾*d.* per head and £18 1*s.* 6¾*d.* per family in 1908. These figures are, of course, no real indication of what was spent by the adult population which actually consumed the liquor. It is estimated that this class numbers about 55 per cent. of the total population, so that on this basis the *per capita* expenditure is approximately £6 5*s.* per person. Three special causes have been in operation during 1909 to reduce the consumption of alcoholic liquors. Two of them are indicated in the Parliamentary Paper issued last year in anticipation of the Budget: 'The diminishing consumption of alcoholic liquors, though to some extent attributable to the recent depression in trade, is principally the result of a continuous change in the habits of the people, which has been in progress for some time and seems likely to be permanent.' The third is the increased price of spirits, which has been the chief factor in causing the enormous reduction of over 7,000,000 gallons in the quantity of spirits consumed. The national expenditure on alcoholic liquors, notwithstanding its marked reduction since the years 1899 and 1900, still represents an appalling waste of the national resources. According to the syllabus of the Board of Education on Temperance and Hygiene, about two-thirds of the total drink bill, or nearly £2,000,000 a week, is spent by the working classes. If they are above the poverty line this wasted expenditure tends to bring them under it; if they are under it, the waste aggravates their difficulties. Drink-caused poverty is the worst kind of poverty, because it does not make the best of the available resources, and is invariably associated with moral and physical degradation. The burden of the drink evil falls heavily upon the woman; it crushes the child."

It is interesting to see that Mr. Wilson estimates the additional spirit duty paid within the year at £3,000,000, and that the drink trade gained a sum of half that amount.

THE NEW EXAMINATION HALL OF THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.

To the Editor of THE LANCET.

SIR,—The last sentence in the description of these buildings which you published last week is a little mysterious. The description says that the figures in the frieze will carry symbolic instruments. What instruments are symbolic of examinations? I can only think of the plough.

I am, Sir, yours faithfully,

TRIFFLER.

HEALTH AND SANITATION IN NORTHERN NIGERIA.

THE report for 1908-09, just presented by the Colonial Office to both Houses of Parliament, states, *inter alia*, that the average number of Europeans resident in the Protectorate during the year, exclusive of those engaged on the northern extension of the Lagos Railway, was 499, of whom 399 were officials and 100 non-officials—481 males and 18 females. The estimated native population of the Protectorate is 7,164,751—an average of 28·02 to the square mile. There were ten deaths from all causes among the Europeans during the year, all being officials; six deaths which occurred on the northern extension of the Lagos Railway are not included. 48 Europeans were invalided home—28 officials and 20 non-officials; there were five deaths amongst officials on leave. The general character of the diseases prevailing showed little or no change. The case mortality of blackwater fever was above the average of the last five years, but the cases were fewer in number, the actual number of admissions being 14 with four

deaths. The greatest amount of sickness among Europeans was due, as in former years, to malaria. The total number of admissions from this disease (blackwater fever being classified separately) was 307, compared with 318 the previous year, 370 in 1906, 445 in 1905, and 515 in 1904—a progressive diminution in the number of cases, notwithstanding the increase of the European population. The native death-rate, so far as ascertainable, varied but little throughout the year, and owing to the absence of any serious epidemic was much lower than in any year since the Protectorate was established. The average number of Europeans employed on the railway was 120, among whom there were two deaths during the year and nine invaliding—a very satisfactory record considering the high rate of mortality on other railway construction work in West Africa. A native hospital has been erected at Baro and a European sick rest-house, which will be replaced this year by a European hospital on the summit of a hill. Three cases of sleeping sickness were admitted to hospital during the year—all natives. There is considerable evidence to show that this disease is not uncommon on the Benue, but the portion of the Protectorate where it is said to occur has not yet been thoroughly examined. It is apparently confined to small areas and has never assumed the form of epidemics such as have occurred in East Africa. The highest shade temperature recorded during the year was 119° F. at Maifoni in March, and the lowest 46° at Geidam in January. The highest mean temperature was 84° at Baro, and the lowest 75° at Zaria. More rain fell in Bassa than in any other province, the rainfall there totalling 58·77 inches. The largest amount (5 inches) recorded for one day fell at Ilorin in October. The rainfall at Zungeru was 48·78 inches; Lokoja, 44·12; Ilorin, 55·46; Maifoni, 23·3; Bauchi, 47·88; Kano, 34·86; and Sokoto, 20·44 inches.

WEAK MILK AT HASTINGS WORKHOUSE.

IN whatever light Mr. Harold Goodwin regards the inmates of Hastings workhouse there is no justification for his supplying the institution with added water in the milk when the guardians have already seen that a sufficient supply of water is procurable at the call of the officials. On the delivery of the milk on Feb. 15th samples were taken and it was found that the milk contained 2·5 per cent. of fat, 8 per cent. of solids not fat, and 89·5 per cent. of water. These percentages were equivalent to an addition of 10 per cent. of water to milk containing fat 2·8 per cent., solids not fat 8·9 per cent., and water 88·3 per cent. Inasmuch as Goodwin was the milk contractor and as last year he supplied no fewer than 14,350 gallons of the lacteal fluid to the workhouse the magistrates did not err on the side of severity when they imposed a fine of £10 and costs.

WESTON AND HIS WALKS.

IN THE LANCET of 1876 and 1877 we published some remarks concerning the American pedestrian, Edward Payson Weston, and later on some papers by Dr. F. W. Pavy on observations connected with his metabolism. Mr. Weston is now nearly 72 years of age, but he is engaged upon a great transcontinental walk "from ocean to ocean in 90 days." He departed from the City Hall, Los Angeles, California, on Feb. 1st last, and expects to reach the City Hall, New York, on May 17th, a distance of 3483 miles from the starting point. The scheduled time of 90 days does not include Sundays, when he rests. He claims that during the past 42 years he has walked in public a distance thrice the circumference of the earth. In 1876 he walked at the Agricultural Hall, Islington, a total of 1015 miles within a period of five consecutive weeks, before 200,000 people. In the same year he also walked at Edinburgh and Liverpool. In 1877 he walked at Edinburgh, Bradford, Bristol, Newcastle-on-Tyne, and Hull. In 1878 he walked at Newcastle-on-Tyne, Glasgow, and Bradford. In 1879 at the Agricultural Hall, London, he won the "Astley Belt" by covering a distance of 550 miles in 141 hours and 44 minutes. From Nov. 21st, 1883, to March 15th, 1884, under the auspices of the Church of England Temperance Society, Mr. Weston walked a distance of 50 miles per day for 100 days, without walking on Sundays, making a distance of 5000 miles. At the close of each day's walk he delivered a brief lecture on the subject of temperance. It will be interesting to see whether Mr. Weston will accomplish his ambitious task now that he is a septuagenarian.

A. B. C.—The question of branch surgeries is a very difficult one. Where they are instituted for the good of the public, both with a view to save the public time and assist the general practitioner in his routine of work, they are of course legitimate. Where a man puts up a plate in the heart of other men's practices he must expect some criticism. It is quite impossible to lay down any definite rule as to what is legitimate rivalry and what is over-sharp competition. Every practitioner in these matters must be a law to himself. The correspondent who asked us questions on this matter also desired to know the position with regard to medical men canvassing for club appointments. The General Medical Council has expressed a strong opinion with regard to all canvassing, whether by the medical man personally or by an agent in his behalf, and any medical man who wilfully offends in this direction runs a risk of being removed from the Medical Register.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 20, Hanover-square, W.

WEDNESDAY.

BALNEOLOGICAL AND CLIMATOLOGICAL SECTION (Hon. Secretaries—Septimus Sunderland, F. A. de T. Mouillot) at 15, Cavendish-square, W.: at 5.30 P.M.

Adjourned Discussion:
On Arthritis Deformans (to be re-opened by Dr. A. E. Garrod).

Paper:
Dr. Leigh Canney (Assouan): The Climate of Egypt and North Africa in Relation to the Treatment of Disease.

THURSDAY.

DERMATOLOGICAL SECTION (Hon. Secretaries—E. G. Graham Little, H. G. Adamson) at 11, Chandos-street, W.: at 5 P.M.

Cases:
Mr. J. E. R. MacDonagh: (1) Dermatitis Herpetiformis; (2) Some Cases of Syphilis illustrating the Importance of Wassermann's Reaction.
And other Cases.

FRIDAY.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN (Hon. Secretaries—E. I. Spriggs, J. P. Lockhart Mummery, J. T. Leon) at 11, Chandos-street, W.: at 4.30 P.M.

Cases:
Dr. F. Langmead: Case of Congenital Scoliosis due to Spinal Malformation.
Dr. L. G. Parsons: Case of Congenital Acholuric Jaundice.
And other cases.

Papers:
Dr. F. Langmead: A Short Paper on 80 Consecutive Cases of Wasting Infants Fed on Undiluted Citrated Milk.

EPIDEMIOLOGICAL SECTION (Hon. Secretaries—W. H. Hamer, G. S. Buchanan) at 15, Cavendish-square, W.: at 8.30 P.M.

Paper:
Dr. Sheridan Delépine: Contribution to the Study of the Influences Determining the Prevalence of Bovine Tuberculous Mastitis.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MEDICAL GRADUATES' COLLEGE AND POLYCLINIC, 22, Chenies-street, W.C.

MONDAY.—4 P.M., Dr. S. E. Dore: Clinique (Skin). 5.15 P.M., Lecture:—Dr. C. O. Hawthorne: Mind Blindness.

TUESDAY.—4 P.M., Dr. G. A. Sutherland: Clinique (Medical). 5.15 P.M., Lecture:—Dr. S. Spicer: The Modern Treatment of Hay Fever.

WEDNESDAY.—4 P.M., Mr. A. Edmunds: Clinique (Surgical). 5.15 P.M., Lecture:—Dr. W. H. B. Stoddart: Neurasthenia and Psychasthenia.

THURSDAY.—4 P.M., Dr. H. Campbell: Clinique (Medical). 5.15 P.M., Lecture:—Mr. R. Lake: The Diagnosis and Indications for Operation in Suppurative Disease of the Labyrinth.

FRIDAY.—4 P.M., Mr. H. L. Eason: Clinique (Eye).

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—2.30 P.M., Dr. Saunders: Demonstration of Cases (Medical Wards).

THURSDAY.—4 P.M., Mr. Baldwin: Demonstration of Cases (Surgical Wards).

FRIDAY.—3 P.M., Dr. S. Taylor: Demonstration of Cases (Medical Wards).

LONDON SCHOOL OF CLINICAL MEDICINE, Dreadnought Hospital, Greenwich.

MONDAY.—2 P.M., Operations. 2.15 P.M., Mr. Turner: Surgery. 3.15 P.M., Sir Dyce Duckworth: Medicine. 4 P.M., Mr. R. Lake: Ear and Throat. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 3.15 P.M., Special Lecture:—Sir Dyce Duckworth: The Treatment of Cardiac Dilation.

TUESDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Wells: Medicine. 3.15 P.M., Mr. R. Carling: Surgery. 4 P.M., Sir M. Morris: Diseases of the Skin. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

WEDNESDAY.—2 P.M., Operations. 2.15 P.M., Dr. F. Taylor: Medicine. 3.30 P.M., Mr. Cargill: Ophthalmology. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

THURSDAY.—2 P.M., Operations. 2.15 P.M., Dr. G. Rankin: Medicine. 3.15 P.M., Sir W. Bennett: Surgery. 4 P.M., Dr. Sale-Barker: Radiography. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Ear and Throat. 3.15 P.M., Special Lecture:—Sir William Bennett: Treatment of Tuberculous Glands.

FRIDAY.—2 P.M., Operations. 2.15 P.M., Dr. R. Bradford: Medicine. 3.15 P.M., Mr. McGavin: Surgery. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 12 noon, Skin.

SATURDAY.—2 P.M., Operations. Out-patient Demonstrations:—10 A.M., Surgical and Medical. 11 A.M., Eye.

CENTRAL LONDON THROAT AND EAR HOSPITAL, Gray's Inn-road, W.C.

TUESDAY.—3.45 P.M., Lecture:—Mr. W. Stuart-Low: Accessory Sinuses.

FRIDAY.—3.45 P.M., Lecture:—Mr. W. Stuart-Low: Accessory Sinuses.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton, S.W.

WEDNESDAY.—4 P.M., Lecture:—Dr. C. Wall: Intra-thoracic Growths.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

TUESDAY.—3 P.M., Mr. A. Harden: The Modern Development of the Problem of Alcoholic Fermentation. (Lecture III.)

FRIDAY.—9 P.M., Mr. T. T. Baker: The Telegraphy of Photographs, Wireless and by Wire.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY (18th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (2 P.M.), St. Mary's (2.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Royal Free (2 P.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M.), St. Mark's (2.30 P.M.), Central London Throat and Ear (Minor 9 A.M., Major 2 P.M.),

TUESDAY (19th).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Soho-square (2 P.M.), Chelsea (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M., Ophthalmic, 2 P.M.), Tottenham (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

WEDNESDAY (20th).—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), St. George's (Ophthalmic, 1 P.M.), St. Mary's (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Gt. Northern Central (2.30 P.M.), Westminster (2 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Cancer (2 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Ear (2 P.M.), Royal Orthopædic (3 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M., Dental, 2 P.M.), Tottenham (Ophthalmic, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

THURSDAY (21st).—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (1.30 P.M.), St. Mary's (2.30 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.), Metropolitan (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Royal Orthopædic (9 A.M.), Royal Ear (2 P.M.), Children, Gt. Ormond-street (9 A.M. and 2 P.M.), Tottenham (Gynæcological, 2.30 P.M.), West London (2.30 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

FRIDAY (22nd).—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Middlesex (1.30 P.M.), Charing Cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), St. Mary's (2 P.M.), Ophthalmic (10 A.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.), West London (2.30 P.M.), London Throat (9.30 A.M.), Samaritan (9.30 A.M. and 2.30 P.M.), Throat, Golden-square (9.30 A.M.), City Orthopædic (2.30 P.M.), Soho-square (2 P.M.), Children, Gt. Ormond-street (9 A.M., Aural, 2 P.M.), Tottenham (2.30 P.M.), St. Peter's (2 P.M.), Central London Throat and Ear (Minor, 9 A.M., Major, 2 P.M.).

SATURDAY (23rd).—Royal Free (9 A.M.), London (2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), University College (9.15 A.M.), Charing Cross (2 P.M.), St. George's (1 P.M.), St. Mary's (10 A.M.), Throat, Golden-square (9.30 A.M.), Guy's (1.30 P.M.), Children, Gt. Ormond-street (9 A.M. and 9.30 A.M.), West London (2.30 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will insure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rate of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at these rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—Messrs. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

An original and novel feature of "THE LANCET General Advertiser" is a Special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice but is in itself an *additional* advertisement.

Advertisements (to insure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials, &c., sent to the Office in reply to advertisements; copies only should be forwarded.

Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Office, 423, Strand, London, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 35, Rue Franklin, Asnières, Paris.

ABSTRACT OF

The Hunterian Oration

ON

SOME PRINCIPLES IN THE TREATMENT OF CHRONIC DISEASE.

Delivered before the Hunterian Society on Feb. 9th, 1910,

BY R. FORTESCUE FOX, M.D. LOND., M.R.C.P. LOND., F.R. MET. SOC.,

CONSULTING PHYSICIAN, MINERAL WATER HOSPITAL, STRATHPEFFER.

MR. PRESIDENT AND GENTLEMEN,—It has been my lot for the greater part of my professional life to be brought into contact with certain classes of chronic disorders. In their origin many streams of causation are intermingled. In their clinical history they present many forms and many phases. They vary with age and sex and inheritance. The treatment also of these conditions is equally wide and various in character. In chronic disease assistance is not unnaturally sought, not only within the borders of professional art, but from whatever source appears to hold out a prospect of relief. And it has seemed to me that it might be useful to attempt to define some at least of the principles of medical treatment, and to trace their beneficent operation in a group of chronic disorders. I make no reference to local diseases, or to the diseases of the early or evolutionary period of life. All chronic diseases—indeed, disease of every kind—may be said to begin locally, a truth that was long ago pointed out by Broussais. Our present concern is with their later or constitutional phases. Undoubtedly the same principles of treatment are applicable to early life and to local disease, but I refer now to some general maladies of the middle and later periods of life, which are—to use an expression that we owe to Dr. Hughlings Jackson—diseases, not of evolution, but of dissolution. It is now happily realised that disease is only a modification of normal action and structure. From the normal decay of living forms we may distinguish it, in that disease is premature and partial, wanting in balance, and accompanied by disturbing reactions, whilst the normal process of dissolution is general and nicely proportioned, and tranquil.

SCIENCE AND ART IN MEDICINE.

The history of medicine is strewn with the wrecks of many doctrines and many systems. One after the other they have dominated the mind of men for generations and hindered progress by a fallacious aspect of finality. What wonder, then, that when the way of scientific inquiry was fully opened there should be an aversion to the very name of system in medicine. Attention, long wasted on speculations, was then turned to observation and experiment—physical, chemical, anatomical, and physiological—and as a result of a patient study of Nature there has been since Hunter's time a marvellous accumulation of data, not only with reference to the living organism, but to its environment. Every year the energy of observation and research in medicine increases the raw material of knowledge. Data are now constantly multiplied and magnified to such an extent that a word of warning may perhaps be needed. The mere accumulation of facts and figures serves no useful purpose. A fact to be fruitful must have something added to it. Hunter and Darwin were not only observers but interpreters of nature. Men are apt to think they follow them by piling new facts together, as the ancients heaped stones over the graves of their chiefs. Burdensome multitudinous mountains of unrelated facts may even conceal the truth that really concerns us. Therefore, whilst rejecting final systems, let us also beware of the finality of facts. They are only the raw material with which the scientific imagination builds up hypotheses and goes from step to step in the ascertainment of principles. Darwin's work was as fruitful in principles as in data. He says of himself almost regretfully that his mind became "a kind of machine for grinding general laws out of large collections of facts." I would urge that this process is especially needful in the advancement of medicine. More particularly in this period, cut adrift from the doctrines of the past, may we well pause to consider the principles upon which we are working. They are in part provisional, they are far from final.

It should not be forgotten that medical treatment is an art, resting not alone upon the accepted principles of the time, but upon a much wider and more uncertain basis. Practices sometimes survive when the ideas that gave them origin have long been extinct. If the basis of art be wide, to a grotesque and exaggerated degree in popular medicine, it is also wide in professional practice. Remedies and methods are employed that rest upon a similar uncertain and ill-defined foundation. Sometimes in default of principles, and sometimes in their despite, we are content to accept the sanctions of custom and tradition, to found ourselves upon the authority of great masters, who in their turn rested upon dogmas that have withered in the light of better knowledge. Some of our most valued remedies were held to be supernatural, and come from the days of plant worship. It is stated in the Rig Veda that as Ahriman had created 10,000 diseases, so Ormuzd gave mankind the same number of healing plants.

Opium, castor oil, scilla, galbanum, scammony, tragacanth, oak galls, male fern, and elaterium are recommended to us by Theophrastus in the third century B.C., and many or all of these were probably used by Hippocrates. It is interesting to notice that stramonium and aloes, which were also used by the Greeks, were among the drugs recommended many centuries afterwards to our King Alfred by Helias, Patriarch of Jerusalem. Some valuable remedies, such as Indian hemp (b'hanga or haschish), tamarind, and asafœtida, must have been used in the East from a remote antiquity, and are mentioned in the ancient Sanskrit writings; rhubarb is described in a Chinese herbal of 2790 B.C., written by the Emperor physician of the day; the use of gamboge and camphor came from the same country; colocynth was familiar to the ancient Greeks and Romans, whilst senna, cubebs, and probably nux vomica were introduced by the Arabian physicians into Europe. For other drugs we are indebted to the more recent experience of primitive tribes. We have calumba from the forests of East Africa, kino from West Africa, buchu from the Hottentots at the Cape of Good Hope, lobelia and podophyllum from the aborigines of North America, ipecacuanha and pareira brava from Brazil, jalap from Mexico, quassia and guaiacum from the West Indies, and sarsaparilla, copaiba, and cinchona from the slopes of the Andes or the tropical parts of South America.[1] The same process of the reinforcement of the healing art continues to our own time, for have we not eucalyptus from the aborigines of Australia and coca from the mountaineers of Peru? And only gradually and after many years is the empirical use of our remedies substantiated and explained by scientific inquiry. A similar observation applies with even greater force to dietetic treatment, and the use of waters and baths, to physical treatment and regimen, and mental therapeutics. These are at present regulated far more by custom and authority and experience than by exact scientific analysis.

In these days the scientific method has opened up so many provinces of knowledge that there is a pardonable haste to make it the touchstone of all truth, in medicine and elsewhere, and to discredit every opinion and practice that has not a clearly ascertained rational basis. A moment's reflection upon the history of medical science and medical art, their true relations and scope, suffices to show that this is as yet an impossible claim. There can, of course, be no discords in true knowledge, but there is no finality. The mind must always receive whatever comes to it authorised by sufficient evidence and reject whatever is shown to be incompatible with ascertained fact. Art is called upon to occupy a field co-extensive with life, far too great for science to define as yet. It is a proud justification of our art that again and again after many centuries science in a later time has established and confirmed its methods upon a rational and permanent basis. In medicine practice has always been in advance of theory, but they are one in object and must ultimately be in full accord.

The example of the man whom we celebrate to-night illustrates the union of science and art in one person. John Hunter is first of all a naturalist, quick as a sensitive plate to receive and record the authentic impressions of nature; then an experimentalist, putting questions and loyally abiding the answers; then a theorist, using a trained

imagination to classify and coördinate his data; lastly, a medical artist—a practitioner—furnished with the best available methods, whether drawn from the general experience or founded upon scientific inquiry. In spite of Hunter's dislike of systems and his pretended abhorrence of definitions the *growth of principles*—shall we say the orderly crystallisation of knowledge?—was always going on in his mind and gave simplicity and distinction to his teaching. Therefore in the endeavour to examine some of the principles now underlying the daily treatment of disease in the twentieth century it cannot be said that we are wandering from the Hunterian tradition.

TREATMENT OF CHRONIC DISEASE: ILLUSTRATIVE CASES.

It has been well stated by Wilks that "disease is slow," that it is by nature gradual and chronic, that so-called "acute diseases" are but accidental events in its course or at its close.[2] The distinction between acute and chronic, though somewhat artificial, is, however, more valid from the therapeutic point of view. As regards acute diseases, we are all now pretty much agreed upon the principles of treatment. We recognise that for the acute phase of disease there is a limited course and a natural process of recovery with wide variations in individual cases. Our aim is, therefore, in the first place to remove the impediments to recovery, to place the patient in the best place for recovery, to relieve pain, and to mitigate dangerous reaction.[3] These are familiar principles, but they involve not only accurate knowledge of the natural process, but also from time to time active interposition in the conduct of the case. It may, however, be described as *indirect* or *adjuvant* treatment, taking the form sometimes of "masterly inactivity," and sometimes of active interference.

We have, secondly, the *specific* or directly curative treatment of acute disease. Specific treatment is to-day the most important weapon of therapeutics. The principle upon which it relies is the counteraction of specific poison and the production of immunity. At present limited in range to a few maladies, such as small-pox, diphtheria, dysentery, tetanus, snake-bite, hydrophobia, enteric fever, &c., the operation of this principle, once so much derided, is probably destined to cover the whole field of diseases owning a specific origin, whether in the acute or chronic phase. It is interesting to notice that Hunter said, "It is more than probable that most diseases have some specific quality." Obviously the problem of treatment becomes by so much the simpler when this factor of causation has been ascertained. With regard to most chronic affections, their treatment is difficult, because our knowledge of their causation is imperfect. The following history illustrates a not uncommon malady in the middle period of life and the methods of treatment that were employed to overcome it.

CASE 1.—A lady, of gouty family, contracted what was described as "blood poisoning" at 36 years of age. It began acutely with gastro-enteric disturbance, and continued for two years in the form of recurring diarrhœa. There were much loss of weight (6 stones in 12 months) and prolonged nervous prostration. Failing benefit from drugs, recourse was had to hydropathic treatment. Later she went for three seasons to Kissingen, with marked relief to the intestinal catarrh. For many years the symptoms recurred at intervals, especially after an attack of influenza at 46 years of age. At this time the skin was dry and inactive, with much mucoid subcutaneous deposit, the peripheral circulation was very defective, and there was a troublesome liability to what she termed "internal chills." Any considerable fatigue, whether physical or mental, brought on attacks of insomnia, with palpitation and distressing restlessness. The heart and kidneys appeared to be healthy. Two years later (æt. 49) after a course of peat baths at Strathpeffer the condition of habitual chilliness gave place to a sense of heat, with profuse and frequent perspirations. In this condition the heart's action became rapid and the abdominal aorta was dilated, throbbing, and tender to touch. The sense of pulsation throughout the body was distressing, with mental and physical restlessness. Absence from home in a cool and bracing air and a course of salt baths at 90° F. were prescribed, with much relief to the vaso-motor disturbance. At this time the late Dr. Sansom regarded the case as one of Graves's disease, although the thyroid gland was smaller than ordinary and there was no exophthalmos, which subsequently developed, but only to a slight extent. As the summer came on it was found necessary to reduce the temperature of the baths, and in July the patient lay daily for two hours in salt water at 88°. She then went for four months to the north of Scotland, and cold needle baths did much to restore normal vaso-motor tone. From the ages of 49 to 55 years the patient had many attacks of profuse and offensive diarrhœa, sometimes with a little mucus but more often without. In one attack, which lasted for 40 hours, 20 pints of an offensive brown fluid were passed by the bowel and the patient lost 10 pounds of weight in two days. Before these attacks there was generally a "heat wave" for perhaps two weeks, the heart's action was rapid and galloping, and there was a sense of general fulness and distress. The attack brought marked relief to these symptoms, and the pulse usually became slow and slightly irregular with an increase of blood pressure to 150 or 160. In the colder months of the year she remained fairly well, but in the summer and autumn always sought the cooler climates of the north—in Norway or the Shetlands, or Strathpeffer, where she took brine baths at 10° or 13° below blood heat. The keen air of northern latitudes made her, to use her own words, "alive in every fibre," but in some places hindered sleep, whilst in other localities, such as Leadhills (1300 feet) in the south of Scotland, she could sleep soundly. The catamenia ceased at 55, after which she enjoyed very good health for 18 months, accompanied by a new and favourable development—viz., localised gouty deposits in the neighbourhood of the joints. Again two years later she is still liable to vaso-motor attacks in a much slighter degree, usually brought on by over-fatigue. These are always controlled by a course of effervescing or salt baths, and judicious rest and change of climate.

The middle age was regarded by Hunter himself as the epoch *par excellence* of nervous disorders. The growth of civilisation during the century that has elapsed since his time does not seem to have lessened the strain upon the nerve centres in middle life. No doubt in most cases the definite breakdown at 48 or 50 is preceded by some years in which disorder of function is sufficiently obvious and could be readily dealt with. The toxic element, as in the case that has been cited, is often a prominent factor. Toxic disease suggests a microbial origin, and therefore a specific treatment. To specific treatment we rightly look, if not to supply an antidote, to restore the lost immunity to specific invasion. This guiding principle plainly emerges from recent research and experience. But we have often to deal with toxic diseases of unknown origin. Specific treatment is therefore as yet impossible. We are driven back upon a second line of defence. Our guiding principle must now be to aid elimination and to mitigate the violence of reaction.

In this case there was an extreme disturbance of circulation. I wish to emphasise the fact that toxic circulatory disturbances can often be controlled by a judicious use of baths and climates. Sedative treatment, which as we know has a valuable application to acute disease, must also be assigned an equally important place in dealing with chronic affections. The treatment of circulatory disorders has been of late too exclusively associated with one particular form of bath at one continental resort. The truth is that cooling baths of various kinds and cool climates are of the greatest value, particularly in the different degrees of vaso-motor paralysis. The case that has been related shows that it is possible by such means to control an extreme form of vaso-motor disorder during a period of ten years, and to tide over the dangerous disturbance of the climacteric epoch.

CASE 2.—This case illustrates another condition belonging to the later and middle periods of life, and presents an interesting contrast to the condition just described. Here also the circulation and vaso-motor system are involved, but in a different manner. The patient, a married woman, aged 48 years, complained of "rheumatism" in the knees of three years' duration. There were some pain and swelling with slight crepitation in both the knee-joints and in one wrist. To these local conditions there was added some general plethora, with attacks of slight vertigo. The menses were natural. A course of sulphur waters and baths was taken. Six years later (aged 54) she reported that the menses had just ceased and that the rheumatism had subsided under the previous treatment. Slight symptoms of angina pectoris were, however, now apparent. An occasional course of alkalies and a more restful life were enjoined. It was noticed that she remained fairly well while the skin acted freely in a warm

climate, in which as a rule she resided. At 57 there was a smart hæmorrhage from the rectum, at 58 transient right hemiplegia with difficulty of speech for 24 hours. This passed off, but she remained subject to vertigo, faintness, and dyspnœa, and there was a chronic condition of dryness and chilliness of the skin. For the "heart weakness" and affection of breathing she had been given many cardiac tonics without benefit. On her return to England at 59 the heart was found to be hypertrophied, the action labouring and uneasy, the peripheral vessels everywhere contracted, the head hot and flushed, and the extremities habitually cold. The blood pressure was 160 millimetres. The late Mr. Marcus Gunn reported that the retinal vessels were small and evidently sclerosed. Some partial relief had been obtained by the use of calomel, iodides, and trinitrin. I was impressed by the contrasted condition of different areas of the circulation in the patient. In the cutaneous area and extremities a long-continued vaso-motor spasm appeared to have resulted in a permanent sclerosis of the arterioles, as evidenced by the state of the retinal vessels. On the other hand, a localised loss of vaso-motor tone in other parts was indicated by the congestion of the face and head. It was obvious that this condition imposed increased labour upon the heart and threatened the integrity of the brain, and that drug treatment was of slight avail. I therefore determined on venesection, and this was repeated about twice in the year for six years, from 10 and 20, and on one occasion 24, ounces being taken. At the same time the diet was reduced and meats of all kinds were avoided. Marked and immediate relief of all the symptoms attended every venesection. There has been now (aged 68) no return of the paralytic symptoms, the health is fairly good, and the blood pressure ranges between 140 and 160 millimetres.

I give this history, extending over 20 years, as illustrating a chronic circulatory disorder with abnormalities in the distribution of the blood, in which the arterial pressure is apt to rise to a dangerous level, and in which active and repeated depletion with periods of rest appear to be the best principles of treatment. Baths and local application intended to assist the peripheral circulation are unfortunately often ill borne. The condition is aggravated in our home climates, and relieved by warm and equable temperatures. In this patient there were already signs of abnormal blood pressure at 48, it steadily increased to the climacteric at 55, after which it was accompanied by threatening symptoms. The condition of the surface circulation is undoubtedly related to abnormally high pressures, and hence, *cæteris paribus*, the relief of symptoms in warm climates. A series of observations upon arterial blood pressures in different individuals at different atmospheric temperatures would be of much interest. It would probably show in these cases a defect in the regulating power of the peripheral vaso-motor system.

It will be noticed that the effect of venesection is not at all so mechanical a matter as one might suppose, for the sedative effect on the circulation is out of proportion to the volume of blood removed. This neglected remedy finds, in my opinion, especial usefulness in the plethora which often follows the cessation of the menses, and again in later life in the sudden access of blood pressure that sometimes results from trifling disturbance of health. When these accessions of pressure are promptly relieved, cerebral hæmorrhage can often be averted even when the vessels are in an advanced condition of degeneration.

THE "INTENSIVE" TREATMENT OF CHRONIC DISEASE.

It may be confidently claimed that *sedative* and *eliminative* treatment—and especially in the form of climate and baths—have a special application to the nervous and circulatory disorders of middle life. Within the limits of climatic and balneological treatment, a great variety of these two great remedial influences are included. I am disposed to think that it would be well if the extent of these resources was more widely appreciated by the profession.

There is, however, another principle which underlies the treatment of some inherited and diathetic disorders. Many writers, like Hunter himself, have noticed that chronic diseases have sometimes been cured by acute ones. The chronic sluggish action of indefinite duration is replaced by a more intense action, that may run a short course and result in cure. Two actions cannot co-exist, and it may be better to have a brief acute action than a prolonged and chronic one. This is not a new doctrine. The principle on which it rests is undoubtedly true, and probably explains the beneficial effects of caustics, astringents, and blisters in many chronic local conditions. On this principle it is that Bacon seriously recommends "surfeits and excesses, or fasting or exercises" for persons with a chronic disease, "for," says he, "Diseases of continuance get an adventitious strength from custom, besides their material cause, so that the breaking of the custom doth leave them only to their first cause, which if it be anything weak, will fall off. ..... Besides such excesses do excite and spur nature, which therefore riseth more forcibly against the disease."[4] The rationale of this method is, by the introduction of a new influence, to modify or change the existing perturbation and to reinforce or intensify the natural reaction, which by hypothesis tends to cure. A striking modern instance of what may be called *intensive* treatment is furnished by Bier's methods for increasing the circulation of the affected part. The slow and obstinate course of disease in tissues like the cartilages scantily supplied with blood is familiar to us all. It may be noticed in passing that specific treatment is also an intensive treatment, for it establishes immunity by evoking an increased reaction in the tissues.

The experience of all spa physicians has shown that in cases of rheumatism and gout the use of waters and baths produces an initial increase of reaction, sometimes in a slight and insensible degree, but often accompanied by disturbing symptoms. Pains and stiffness are increased, joints, which perhaps had been long forgotten by the patient, become tender and swollen, and in cases of unstable equilibrium acute attacks may supervene. Such incidents are met with in the most favourable cases, and are often followed by a prolonged immunity from the symptoms.[5] Intensive treatment is one of the most valued elements in balneological practice, although it must be carefully watched and limited, and combined with an increase of elimination. Moreover, it can only safely be used where there is a fairly good dormant power of reaction. The following historic case, for which I am chiefly indebted to the account left by Sir Everard Home,[6] may illustrate the thesis that I have endeavoured to advance.

CASE 3.—John Hunter was a powerfully built man, short of stature, of a forcible and passionate nature, and—at all events in his adult age—a man of intense mental energy. In his youth he drank wine according to the custom of his time. At 20 years of age he began a life of application in London, broken later by two years spent at sea, from the ages of 33 to 35. We are told that this change enabled him to throw off an early pulmonary weakness which never afterwards troubled him. It is recorded of him that during the most active years of his life he allowed himself no relaxation or games and but little rest, taking four hours' sleep at night and one hour in the afternoon. At 40 he had his first attack of gout in the feet, which recurred in the spring of the three following years. For this established gouty habit, in spite of his own doctrine that it indicated an effort of nature to relieve an underlying disposition, he appears to have taken no treatment. The following year, at 45 years of age, the gout missed, and in its place occurred the first attack of angina pectoris. This was apparently excited, like many of his subsequent seizures, by mental disturbance. He was pulseless for three-quarters of an hour and only kept himself alive by voluntary respiration. Hunter appears after this time to have discontinued the use of alcohol and observed great spareness of living, to which, no doubt, his marvellous output of mental work may be partly attributed. For the remainder of his life he showed a peculiar intolerance of wine on the occasion of its medicinal use. This is a noteworthy, and indeed almost diagnostic, feature of many cases of gout. Four years passed, and then (aged 49) again in the spring of the year, he was seized with a severe attack of auditory vertigo, of which a minute and interesting description has been preserved. His sense perceptions were painfully heightened and curiously modified[7]; he lost his sense of dimension, position, and relative movements. In his vertigo, accompanied by sickness, objects appeared to revolve with increasing rapidity and then come to rest. The slightest movement of his head seemed like a large excursion in space. For ten days he could not raise his head from the pillow. On getting about he tried to persevere with his work, and then his friends, shocked with his feeble condition and altered appearance, compelled him to go to Bath. Here he drank the waters, remaining at the spa from September to

December, 1777, much against the grain, and then returned to London feeling, as he said, little better. It is stated, however, that on leaving Bath he continued to improve and shortly afterwards regained his health.

As an old balneologist I may here state that this is the normal and favourable experience in the treatment of gout by mineral water. John Hunter should have repeated his treatment for three or four consecutive seasons. The action of those waters which are beneficial in gout may be regarded as two-fold. In the first place they intensify the natural reaction of the tissues and so promote and restore the normal periodic local manifestations of the disease; and secondly, they assist the removal of toxic matter by increased elimination. Hence it is that under spa treatment the gouty symptoms are often aggravated in the first instance, and the good results are not declared for weeks or months. The same observation applies to many other disorders, such as chronic rheumatism and degenerative arthritis, in which treatment is intensive or perturbative in character, and may at first discourage the physician as well as the patient by provoking increased reaction in the tissues.

After this long retreat at Bath, under the intensive and eliminative action of the waters, and in a sedative climate, we hear of no further breakdown for several years. He had slight attacks of giddiness and the friendly podagra recurred now and then. But at 57 years of age, once more in April, a serious attack of angina occurred. Slight seizures continued all the summer, only relieved with the appearance of gout in the toe. That there was now an active change going on in the coats of the vessels is suggested by a note of Sir E. Home that he found some "contraction" of the arteries and tenderness along their trunks. The nervous element is indicated by attacks of polyuria. This year Hunter tried Tunbridge Wells for a short time. If, a gouty subject, he drank the waters, it is not surprising that he became worse. In September he returned to Bath, again taking the thermal waters and using hot baths and foot-baths on alternate days. It is interesting to know that for three weeks he felt no benefit, that at the beginning of the fourth week he began to improve, and after six weeks returned to London markedly better. The famous portrait by Sir Joshua Reynolds at the College of Surgeons belongs to this period. During the ensuing years his physical powers became more limited, his health precarious, and attacks of pain frequent. In spite of these warnings of progressive degenerative change Hunter continued his work and died in harness from angina pectoris at 64.

A similar story could be told of too many members of our profession—both John and William Hunter, Sydenham, and Cheselden, and in our own time Andrew Clark—gout or gouty symptoms for many years, and vascular degeneration and angina or hæmorrhage at the end, at 63, 64, or 65 years of age. Brain workers seem to be under a special liability in this regard, and many have died from Hunter's complaint in the early fifties, like George Whitfield and Arnold of Rugby. It is not improbable that King Alfred died from the same disease at 51. Is it too much to say that many such lives, lost in the full vigour of their intellectual powers, might have been saved? A reasonable curtailment of mental work, provision of congenial relaxation and sufficient hours of rest, a recourse during a portion of each year to sedative climates, and repeated and persevering use of balneological treatment,—these are measures upon which we can now confidently rely to maintain the balance of health and delay the process of dissolution, at least for a time and often for many fruitful years.

RETARDATION OF DISEASE.

It has been well said that the *retardation* of disease is a prime function of medicine.[8] After all, cures are but relative. In the intricate chemistry of the living body the processes of disease may be wholly or partially arrested. Even malignant growth may become quiescent. The problem of treatment, therefore, sometimes resolves itself into retarding a morbid process to the natural limit of life. We daily meet with chronic conditions of arrested or slowly progressive disease, with damaged organs and limited powers of resistance. Such affections are common in middle life, and in their limitations they resemble old age. The natural provision for withstanding disturbing influences (for example, the reaction to cold) has been lost—and also more or less the normal capacity for work. The treatment of such conditions is therefore mainly by way of *protection* and *adjustment*. A wise treatment should provide efficient protection against vicissitudes of temperature and other disturbing influences, and also adjust the burden or work—food, exercise, mental work—to the lowered capacity.

The effect of warmth and food in maintaining immunity against many specific invasions is a familiar fact in the history of epidemics. The same observation has been made with regard to the lower animals. Chickens are made susceptible to anthrax by exposure to cold, pigeons by starvation, and white rats by a vegetable diet.[9] A friend whose mental power is as remarkable as his physical resistance and reaction are limited by circulatory disorder writes me that the secret of health in his case is the prevention of "colds." And to avoid colds or chills he must not let down his bodily heat even for half an hour. It is fatal for even the feet to become cold, and he especially condemns linen sheets and the dressing and undressing in chilly rooms. It is obvious that in such cases much protection is requisite in our climate. To how great an extent a guarded life and suitable climatic changes can sometimes retard the processes of disease the following example may show.

CASE 4.—A frail anæmic man, aged 70 years, presented himself for treatment at Strathpeffer. He was much bent with cervical arthritis following on rheumatic fever at 45 and injury received by a fall from his horse. There was also commencing senile degenerative arthritis in the bases of the thumbs and elsewhere. The arteries were hard and tortuous, the action of the heart feeble, digestion weak and uncertain, and there was of late a liability to chills and bronchitis accompanied by pyrexia and threatened heart failure. This had kept him much indoors. It was remarkable how quickly sleep and digestive and muscular and nervous energy improved in the Scottish climate. As I have elsewhere pointed out, Strathpeffer shares with the north-eastern parts of Scotland a singular and bracing climate which makes the whole district from the Dee to Dornoch one great health resort. Over all that region there must be some special virtue in the atmosphere. No meteorological instruments are fine enough to detect and record it, but it is a quality to which living organisms at once respond. It gives an added brightness to the colouring of birds and flowers. It produces in man a feeling of exhilaration and expansion, of added capacity for exertion, increased appetite, and sounder sleep. It affords for elderly and debilitated subjects a very favourable "change of air." In this case warm douches and sulphur baths with massage were also employed. For 12 successive years he continued his yearly visits, even when he could no longer walk. The patient's condition at 78 years of age is well indicated in a brief note by Dr. Hingston Fox: "Senile degeneration, heart now failing, probably dilated atheromatous aorta, high tension, emphysema, risk of bronchitis, will he survive the winter?" After the date of that note he continued to take his month at Strathpeffer for three more seasons, enjoying the fine air and drives among the hills, and died from bronchitis at 81. This gentleman, who was a shrewd and capable observer, was fond of expressing the opinion, founded upon his own experience, that life and tolerable health could often be prolonged for many years in the case of old people if judicious recourse was had to climate and baths. The case illustrates the extent to which the use of these methods of treatment in the later years of life may allay functional disturbance, stimulate a failing heart or digestion, increase the resistance of the tissues to catarrh, and so retard and even arrest degenerative processes.[10]

PRINCIPLES OF TREATMENT.

It is a too familiar fact that disease and ailments of indeterminate causation and indefinite duration make up the greater and more formidable part of the work of the practitioner. Troublesome and insistent symptoms; a history of many failures to remove or even to relieve them; harassing limitations imposed upon the patient; consequent discouragement and the fear of worse evils—these are the features of too many forms of habitual mental and physical ill-health. What a severe test do they impose upon the skill and patience of the medical adviser! Can it be owing to some failure on our part that so many persons seek various irregular methods of treatment, which are alike only in being vaunted with absolute confidence as a panacea for their ills? And confidence, however slender its basis, has sometimes been justified. Have we not found that many habitual invalids who have been overmuch dominated by the consciousness of disease have experienced relief from the

persuasion that disease and pain have no existence? The fact suggests that it may be possible for us to believe too much in material diseases. Can it be that we, having in our art a good and valid ground of confidence, sometimes fail to appreciate it for ourselves and to evoke it in others? In comparison with our fathers we possess a far greater knowledge as to the processes of disease in the tissues. On the other hand, we have lost their confident faith in drugs. To a great extent we have disregarded not only their theories but their remedies. The excesses of polypharmacy and antiphlogistics have reacted strongly towards scepticism. In the case of disorders that run a brief course and tend to cure, good has no doubt resulted from the abandonment of "heroic" therapeutics, but in chronic disease, on the other hand, simple expectancy is doomed to failure. What canons, it may be asked, still remain to us from the practice of our forefathers? What new lights have arisen to advance our therapeutics? It is sometimes needful that we should be reminded even of familiar principles in order to recognise their validity and to apply them with confidence.

It has been sometimes alleged that medical treatment is only symptomatic or opportunist in character. That is to say, that it is content to deal with disturbances as they arise, and does not concern itself with causes. According to this theory we give stimulants for depression and narcotics for excitement, astringents for a flux and cooling remedies for a fever. Such a statement to-day falls very far short of the truth. A treatment of symptoms only requires little knowledge and is quite as often injurious as it is helpful. Our therapeutics are founded not upon symptoms but upon causes, and where we have as yet an incomplete knowledge of causes we have at least the guidance of well-tried and rational principles. Our survey has shown us that for many diseases, and their number is constantly increasing, we have already to our hand a direct *specific* and curative treatment. We have seen that specific and preventive medical treatment applies not only to acute but to chronic disorders, and we believe that it is likely to extend its scope as the knowledge of the causes of disease is increased. Furthermore, we have also recognised another and equally important branch of treatment. Unlike the direct and specific treatment, this does not at once deal with the causes of disease, but is indirect in its operation, removing the results or modifying the tissue reactions of disease. It is upon this indirect treatment that we have mainly to rely in dealing with chronic disorders. We have found its branches four in number, embodying four great principles of the greatest practical value. In the first place *eliminative* treatment removes not only the *materies morbi* but the by-products and deposits that result in so many cases from morbid processes. Secondly and thirdly, we have *sedative* and *intensive* treatment. These two are opposite in principle but often combined in action, because treatment that is sedative in one part may be intensive in another. Sedative treatment abates and minimises the reactions of disease. Since Nature in her reaction so often overshoots the mark, it is needful that we should be able to control and assuage the disturbance, and the employment of many drugs, as well as physical methods, rests upon this principle. Intensive treatment, on the other hand, stirs up and reinforces the natural reactions in chronic disease. Sometimes, in a truly specific manner or from the elective affinity of the tissues, its effects are recognised only in the disordered parts and always in the sense of rendering a chronic action more acute and therefore more susceptible of cure. Last among the indirect methods of treatment, we have the *retardatory*, which includes the principles of *protection* and *adjustment*.

Any discussion, however cursory, of the ground of our therapeutics cannot but enforce the conclusion that no narrow views are possible in medicine. We work in the boundless field of life and of nature. It may be that the increases of knowledge that come to us year by year may seem to throw into greater relief the vast extent of what we do not, and perhaps cannot, know. The advances of science may even bring us moments of discouragement and distrust. We may feel inclined to exclaim, like Lord Melbourne, "I wish I were as sure of any one thing as Tom Macaulay is of everything." Or we may in our daily work be too conscious of the obstacles that we cannot surmount, of the pressure of forces that we cannot stay. We cannot invent a new nature, in which evolution and dissolution shall be replaced by a changeless life. Mutability is of the essence of all things. "The whole creation *moves*," as the poet has said, but from that fact we may draw courage and confidence. For it *moves* according to an unchanging law, of which we are privileged to be, in our humble degree, the interpreters and ministers.

THE DIAGNOSTIC VALUE OF THE CHEMICAL ANALYSIS OF THE GASTRIC CONTENTS AFTER A TEST MEAL.[1]

BY W. H. WILLCOX, M.D., B.SC. LOND., M.R.C.P. LOND.,
PHYSICIAN TO OUT-PATIENTS, ST. MARY'S HOSPITAL, LONDON.

IN clinical cases presenting definite symptoms which may be referred to the stomach the importance of a careful and thorough examination of the gastric contents is becoming increasingly recognised. Several valuable papers on pathological conditions of the stomach and duodenum have recently been published, in which the routine examination of the gastric contents is urged as a valuable aid to diagnosis. Two of the most recent of these were read before the Royal Society of Medicine on March 8th, 1910, and dealt with the gastric disturbance set up by lesions of the appendix.[2] [3]

In all cases presenting persistent gastric symptoms which resist ordinary medical treatment there is no doubt that a careful investigation of the gastric contents should be made, since by this the diagnosis can be placed on a surer basis, and the correct course of treatment be more clearly indicated. It cannot be too strongly urged that in every case on which an operation is to be performed for symptoms referable to the stomach a preliminary examination of the gastric contents on chemical lines should, if possible, be made, since this will in many cases guide the surgeon not only as to the probable diganosis but will also often suggest to him the best course of procedure after the abdomen is opened, and indicate whether a gastro-enterostomy is likely to be of benefit. Of course, it is obvious that in acute perforative lesions of the stomach and duodenum of sudden onset previous investigations are quite out of the question, since immediate operation without any delay is imperative.

As will be subsequently shown, there is no doubt that the composition of the gastric contents after a test meal varies considerably, according to the pathological condition of the stomach, and a particular disease of the stomach is associated with a gastric content of a definite type.

There is no doubt that there are many gastric cases in which the fullest consideration of the clinical symptoms and physical signs does not enable a diagnosis to be made with certainty. The diagnosis may be reduced to perhaps two or three possible pathological conditions. It is in cases of this kind that an analysis of the gastric contents after a test meal is of the utmost value, since it will usually indicate which of the probable diagnoses is the correct one; and the diagnosis based on a careful clinical investigation, together with a thorough chemical investigation of the gastric contents, is rarely at fault. It must, on the other hand, be remembered that the diagnosis of a gastric case must not rest on the chemical analysis of the gastric contents alone.

The first step towards the making of a diagnosis must be a careful consideration of the clinical symptoms and physical signs, and afterwards this should be supplemented by the

[1] A paper read before the Royal Society of Medicine (Pathological Section) on March 15th, 1910.

[3] H. J. Paterson: Appendicular Gastralgia, THE LANCET, March 12th, 1910, p. 708.

chemical investigation of the gastric contents after a test meal. In some cases further valuable information will be elicited by examinations of the stomach and intestines by means of the X rays after a meal containing harmless bismuth compounds in adequate amount.

Examples of cases where the gastric analysis is of great value are those where there have been persistent dyspeptic symptoms for many months, associated with anæmia and wasting, physical examination shows resistance in the epigastric region, and possibly a lump is felt. In cases of this kind the diagnosis usually rests between a chronic ulcer of the stomach and carcinoma, and it is commonly impossible to say which of these lesions is present. If a gastric analysis be made in cases of this kind the diagnosis between the two conditions can be made with practical certainty, and then the prognosis and treatment are clearly indicated.

Again, a case presenting persistent dyspeptic symptoms with dilatation of the stomach may, in the absence of a marked anæmia or wasting, and in the absence of any lump or resistance in the epigastric region, be diagnosed on clinical grounds alone as chronic gastritis or gastric ulcer. The gastric analysis will clearly differentiate between these two conditions.

It is important that in the chemical investigation of the gastric contents a definite technique should be adopted, as it is only by this means that comparative results can be obtained. It is important that the analysis should be made by one accustomed to careful and accurate analytical work.

It is proposed to indicate briefly the methods that have been employed in the pathological chemistry laboratories of St. Mary's Hospital for several years, and which have been found to be simple and accurate and well adapted for clinical work, while at the same time furnishing much valuable and reliable information for purposes of diagnosis. It is not intended to give the full analytical details of the methods employed since these have been already published[4 5], but a brief *résumé* of them will be given, since it is on them that the subsequent deductions are based.

When a case comes under treatment the patient should be kept at rest in bed on a liquid diet for two or three days. If there is great dilatation the stomach should be washed out and completely emptied on the day before the test meal is given. In the early morning after the preliminary treatment a test meal should be given consisting of 1 pint of weak China tea with a little milk and sugar if desired, and a round of thin buttered toast. The patient should rest in bed after taking the test meal, and in one hour's time the contents of the stomach should be syphoned off by means of a soft stomach-tube. It is important that no water should be added to the gastric contents, and this is quite unnecessary, since the syphon action can be readily started by the withdrawal of air from the distal end of the stomach-tube by means of a glass syringe. As much of the gastric contents as will flow should be withdrawn and the quantity measured. The amount obtained gives a measure of the motor power of the stomach.

The general appearance of the contents should be noted as regards colour, viscidity, smell, &c. In gastric carcinoma and chronic gastritis the contents are viscid and slimy, and filter badly. In gastric ulcer and hyperchlorhydria the contents are thin and filter quickly. The appearance of blood and bile can be usually recognised, and further confirmatory tests should be applied for them. In rare cases fæcal material may be suspected and then tests for stercobilin should be applied.

Microscopical and bacteriological examinations of the gastric contents may be made and are of importance in cases of suspected carcinoma, but it is proposed in this paper to deal only with the chemical examination.

The gastric contents should be filtered, care being taken to prevent evaporation; the filtrate is used for the subsequent analysis.

Total acidity.—This should be determined by titration with decinormal barium hydrate solution in the presence of phenolphthalein as indicator. The normal acidity of the gastric contents corresponds to about 0·15 per cent. of hydrochloric acid (from 0·1 to 0·2 per cent.). In hyperchlorhydria and in gastric and duodenal ulcer the total acidity is above normal and usually corresponds to over 0·2 per cent. of hydrochloric acid. In gastritis and gastric carcinoma the acidity is low and usually corresponds to less than 0·1 per cent. of hydrochloric acid. Too much importance must not be attached to the result of the estimation, since the all-important point is how much active hydrochloric acid is present. In some cases the total acidity of the gastric contents may be normal or even above normal, while the active hydrochloric acid is much reduced; in these case a large proportion of the total acidity is due to the presence of organic acids.

Hydrochloric acid.—This may exist as: 1. Free hydrochloric acid—i.e., the acid is not combined with any base, either inorganic or organic. 2. Hydrochloric acid which is combined (*a*) with proteins, and (*b*) with other nitrogenous organic bases. (The above forms constitute the active hydrochloric acid.) 3. Hydrochloric acid which is combined with inorganic bases to form neutral salts—e.g., sodium chloride.

Since the free hydrochloric acid and the hydrochloric acid combined with proteins and organic bases must have all been originally secreted by the gastric glands and represent the amount of hydrochloric acid in the gastric contents secreted by the stomach it is convenient to use the term "active hydrochloric acid" to collectively represent these two forms in which hydrochloric acid is present. The hydrochloric acid which is combined with inorganic bases does not bear any relation to gastric secretion and need not be considered. It was probably taken into the stomach as such in food.

Free hydrochloric acid.—This should be tested for by Töpfer's test (dimethyl-amido-azobenzene solution in alcohol). If the test is positive it should be confirmed by Günzburg's test, which is more reliable, since if organic acids are present in excess Töpfer's test may be positive while no free hydrochloric acid is present. Günzburg's test is not given by organic acids. If Töpfer's test is negative it may be considered that free hydrochloric acid is absent. If desired the free hydrochloric acid may be estimated by titration with decinormal alkali, dimethyl-amido-azobenzene being used as an indicator.

I do not attach much importance to the amount of free hydrochloric acid present, since this is determined largely by the quantity of protein and organic bases in the gastric contents, and the amount of free hydrochloric acid does not indicate the total hydrochloric acid secreted by the stomach, but only the excess of that required to combine with the proteins and organic base. In hyperchlorhydria and gastric ulcer, and also in normal conditions of the stomach, free hydrochloric acid will invariably be found after the above test meal. In gastric carcinoma and chronic gastritis free hydrochloric acid will usually be absent.

Active hydrochloric acid.—This estimation is of the greatest importance in the analysis of the gastric contents, since it represents the total hydrochloric acid secreted by the stomach, and it is the active hydrochloric acid estimate on which reliance is to be based in diagnosis.

The amount of active hydrochloric acid present in the gastric contents usually approximates closely to the total acidity when organic acids are present in small quantity. A rough estimate of the organic acids present is given by the difference between the total acidity and the active hydrochloric acid, the active hydrochloric acid being usually slightly lower than the total acidity. In rare cases the active hydrochloric acid, as determined by the process mentioned below, is slightly higher than the total acidity. In 2 out of 50 recent consecutive test meals analysed at St. Mary's Hospital this was found to be the case. One was from a case of chronic gastric ulcer, where the total acidity was equal to 0·19 per cent. of hydrochloric acid, while the active hydrochloric acid was 0·22 per cent. The other case was one of pernicious anæmia, where the total acidity equalled 0·02 per cent. of hydrochloric acid, while the active hydrochloric acid was 0·04 per cent. The fact of the active hydrochloric acid being slightly higher than the total acidity can be accounted for by a small portion of the hydrochloric acid being combined with some volatile organic base, which forms a salt neutral to phenolphthalein. Professor B. Moore[6] has carefully investigated the cause of this, and

[4] Willcox: The Chemical Examination of the Gastric Contents THE LANCET, June 10th, 1905, p. 1566.

[5] Willcox: The Chemical Examination of the Gastric Contents after a Test Meal, with a New Method for Estimating the Ferment Activity, THE LANCET, July 25th, 1908, p. 220.

[6] Moore: A Study of the Pathological Variations in the Acidity of the Gastric Contents, especially in Relation to Malignant Disease, Bio-Chemical Journal, Liverpool, vol. i., p. 274.

suggests that the hydrochloric acid is combined with an organic base. He has found that the excess of the hydrochloric over the total acidity cannot be explained by the presence of ammonium chloride, because ammonia was not present in sufficient amount to account for it. Emerson[7] has found hexone bases in cancer of the stomach, and it is possible that the presence of these will account for the excess of the active hydrochloric acid over the total acidity in the exceptional cases where this occurs.

The method employed for the estimation of the active hydrochloric acid, which has been found by me to be the most reliable and most suitable for clinical pathological work, is an adaptation of the Volhard process for estimating chlorides (the modified Volhard-Luttke method).[8] This method is one in which the hydrochloric acid is directly estimated. It has been tested with solutions of hydrochloric acid of known strength in the presence of proteins and substances such as those found in gastric contents, and it has been found to give extremely accurate results. Two equal portions of gastric contents are taken: to one, pure sodium carbonate is added in excess; both are evaporated to dryness and ignited at a low red heat so as to thoroughly char and decompose the organic matter present. The chlorides in each are then estimated by Volhard's process in the dishes in which the ignition is done, there being no necessity for any previous filtration before the titration. The difference in the two results gives the amount of active hydrochloric acid present. The method is very simple and quick. It is well adapted for clinical purposes. There is no risk of loss from volatilisation of sodium chloride, since it is quite unnecessary to heat until the ash is white.

The importance of a quantitative determination of the amount of active hydrochloric acid in the gastric contents is very great. The recent physiological research on pancreatic and gastric secretion by Bayliss and Starling,[9] by Edkins,[10] and others shows how great is the importance of the presence of hydrochloric acid in the gastric contents, and suggests the necessity of the medicinal administration of hydrochloric acid in cases where the gastric secretion is insufficient. The work of Bolton[11] on the pathology of gastric ulcer shows the important relationship of an excess of hydrochloric acid in the causation of gastric ulcer. Thus, if gastrotoxin is introduced into the wall of the stomach of an animal, necrosis and ulcer will result, but not if the hydrochloric acid is previously neutralised by sodium bicarbonate. Lenhartz, in his valuable system of treatment of cases of gastric ulcer, has made use of the fact that free hydrochloric acid can be combined in great measure with proteins administered as food. Thus raw eggs, scraped raw, or underdone meat, &c., with milk are given for the purpose of removing free hydrochloric acid and so alleviating the symptoms and promoting the healing of a gastric ulcer.

The quantitative significance of the amount of active hydrochloric acid present in the gastric contents in various pathological conditions of the stomach is dealt with below. The amount of active hydrochloric acid in a normal case with the above technique is about 0·15 per cent. (between 0·1 and 0·2 per cent.). It does not follow, if the active hydrochloric acid is normal in amount, that no pathological lesion of the stomach is present. Clinical symptoms must be carefully considered also. The active hydrochloric acid may be increased (hyperchlorhydria) or diminished (hypochlorhydria). In cases presenting gastric symptoms an increase of hydrochloric acid is commoner than a diminution.

Organic acids.—Lactic acid should always be tested for. A rough estimate of the amount of organic acids present is indicated by the excess of the total acidity over the active hydrochloric acid. When organic acids are absent these two estimations are usually equal. If organic acids are present in appreciable amount, the quantity of volatile and non-volatile acids may be determined. In cases of carcinoma of the stomach and in chronic gastritis lactic acid is commonly found. In hyperchlorhydria and normal conditions of the stomach organic acids are absent or present only in slight traces.

Mucin.—This should always be tested for. It is commonly present in carcinoma of the stomach and in chronic gastritis; also in children it is usually found in cases of congenital pyloric stenosis. In gastric ulcer and hyperchlorhydria mucin is usually absent from the filtered gastric contents.

Sulphocyanides should be tested for. They are usually absent from the gastric contents of children. In adults the presence can only be regarded as evidence of swallowed saliva. The absence of sulphocyanides is no indication of gastric carcinoma, since they are often present in definite amount in this disease.

Ferment activity.—It has been found that the amount of rennin and renninogen present in the gastric contents is a good indication of the quantity of pepsin and pepsinogen, so that an estimate of the former is sufficient for clinical purposes. A quick and accurate method has been published[12] which has been found very serviceable for clinical purposes. The determination of the ferment activity is of great importance and of almost equal value to the estimation of the active hydrochloric acid. In gastric ulcer and hyperchlorhydria the ferment activity is either normal or above normal. In gastric carcinoma, in chronic gastritis, and in pernicious anæmia the ferment activity is usually much reduced. The estimation of the ferment activity is a valuable check on the results obtained from the hydrochloric acid estimation.

TABLE I.—*Gastric Ulcer.*

(Recent cases at St. Mary's Hospital, London.)

No. of case.	Quantity (fluid ounces).	Total acidity as HCl (per cent.).	Mucin in filtrate.	Lactic acid.	Free HCl.	Active HCl (per cent.).	Ferment activity.

12	3½	0·19	,,	,,	,,	0·16	,,
13	6	0·19	,,	,,	Trace.	0·22	,,

Remarks.—Diagnosis confirmed in all of the above cases by subsequent operation (gastro-enterostomy). Cases 2, 3, 5, 6, 11, 12, and 13 were chronic ulcers with much thickening around them, the symptoms being of several years' duration.

The Composition of the Gastric Contents in Various Pathological Conditions.

1. *Gastric and duodenal ulcer* (Table I.).—In the great majority of these cases the active hydrochloric acid is markedly increased and free hydrochloric acid is present in excess. It is extremely rare for the active hydrochloric acid to be below the normal limits. Lactic acid and mucin are usually absent. The ferment activity is generally high. In some cases of chronic ulcer (e.g., Cases 2, 3, 5, 6, 11, 12, and 13, Table I.) the active hydrochloric may not be much raised, or may be only normal in amount, but in these cases free hydrochloric acid is usually present and the ferment activity is high.

Usually in gastric and duodenal ulcer the clinical symptoms are characteristic, and often a lump or thickening is felt in the pyloric region in cases of long standing. In such cases an excessive or even normal amount of active hydrochloric acid, together with a high ferment activity, is a clear indication that gastric carcinoma is not present, and often is a direct indication for gastro-enterostomy, the subsequent prognosis being good. On several occasions cases

Remarks.—Gastric ulcer was found in all these cases.

on physical examination. The size of the tumour had raised the suspicion of carcinoma, but in all of these cases operation or necropsy has shown that the mass was due to an ulcer with inflammatory thickening around it.

The effect of gastro-enterostomy on the composition of the gastric contents in cases of gastric and duodenal ulcers is well illustrated by Table II., where the analysis is shown before and after the operation. It is seen that free hydrochloric acid was often absent after gastro-enterostomy, whereas it was always present before the operation. The active hydrochloric acid was found reduced in every case after the operation. Bile and mucin were generally found present after gastro-enterostomy, and no doubt they have the effect of partially neutralising the hydrochloric acid secreted by the stomach. This may explain the remarkable cessation of symptoms which cases of gastric ulcer present after gastro-enterostomy.

2. *Hyperchlorhydria without any gastric lesion.*—It must be remembered that hyperchlorhydria may exist without any clinical symptoms of its presence. Usually, however, it is associated with definite gastric symptoms, and when this is the case, probably if the symptoms are long continued and resist treatment, some such lesion as ulcer, erosion, or dilatation is present. Hyperchlorhydria is associated with a high ferment activity, and mucin and organic acids are usually absent.

3. *Chlorosis.*—An excess of active hydrochloric acid, together with a high ferment activity, is the usual condition here. Mucin and organic acids are absent. The well-known gastric symptoms so often met with in chlorosis are in great part due to the hyperchlorhydria present.

4. *Neurasthenia with gastralgia.*—Some of these cases are associated with hyperchlorhydria and high ferment activity. More often, however, the active hydrochloric acid and ferments are normal in amount.

5. *Atony of the stomach.*—Sometimes in young females this condition is associated with constipation, and hyperchlorhydria and high ferment activity. In one case the symptoms were so persistent and extended over such a long period in spite of all treatment that gastro-enterostomy was performed, which gave immediate relief. In most cases of gastric atony the active hydrochloric acid is reduced and the ferment activity low.

6. *Mucous colitis.*—Cases of mucous colitis are frequently associated with severe gastric symptoms, and an analysis of the gastric contents in many of these cases shows an increase of the active hydrochloric acid and ferments. In two cases recently seen the colitis was accompanied by a severe and sudden hæmatemesis owing to the gastric ulceration also present, which latter was associated with hyperchlorhydria. In some cases of mucous colitis of several years' standing it has been found that a hyperchlorhydria and high ferment activity in the early part of the disease have later become replaced by a diminution of hydrochloric acid and ferments.

7. *Cholelithiasis.*—This has been frequently found to be associated with hyperchlorhydria. Kaufmann[13] and Friedenwald,[14] and more recently Soltau Fenwick,[15] have called attention to this. The presence of hyperchlorhydria cannot, however, be regarded as an absolutely diagnostic sign of cholelithiasis, because sometimes, as has been found in my series of cases, the active hydrochloric acid was considerably below normal, but gall-stones were found on operation.

8. *Dietetic indiscretions.*—Heavy indigestible food, alcohol, or tobacco in excess may cause hyperchlorhydria, but commonly they set up a chronic gastritis, and then the gastric contents take on the special type of that condition.

9. *General conditions of ill-health.*—Febrile conditions and general diseases, apart from the presence of disease of the stomach, are frequently associated with a diminution of active hydrochloric acid. Professor Moore and Dr. Morton Palmer[16] have called attention to this.

10. *Chronic gastritis* is usually associated with a marked diminution in the active hydrochloric acid; free hydrochloric acid is absent. Mucin is usually present; lactic acid may be. The ferment activity is generally much reduced (*vide* Table III.). The gastric contents of these cases chemically

Remarks.—Diagnosis in these cases was confirmed by examination of blood and by clinical symptoms.

very closely resemble those of gastric carcinoma; hence great care is necessary before arriving at a diagnosis of carcinoma of the stomach. Both the clinical picture and the analytical results must be carefully weighed.

11. *Cirrhosis of the liver.*—Usually in this condition there is a chronic gastritis and the gastric contents have the character of that condition (10).

12. *Pernicious anæmia.*—This condition has been found usually associated with a great diminution of the active hydrochloric acid and an almost complete absence of generally ferment activity (*vide* Table IV.). Mucin was very strongly present. The results obtained in this disease indicate the great importance of giving hydrochloric acid and pepsin to patients suffering from pernicious anæmia.

13. *Achylia gastrica.*—In this condition active hydrochloric acid is almost entirely absent and the intestine appears to perform all the digestive functions. The condition may exist without giving rise to any symptoms, but usually there are definite gastric symptoms, and in some

cases marked intestinal symptoms—e.g., diarrhœa with intervening periods of constipation—may be present. The condition may exist apart from pernicious anæmia or gastric carcinoma.

14. *Cirrhosis of the stomach.*—This is a rare condition, and only a few analyses have been published. Free hydrochloric acid is usually absent, and there is a great diminution of active hydrochloric acid.

15. *Gastric carcinoma.*—There is no doubt that in this condition there is a marked diminution in the active hydrochloric acid and in the ferment activity. When the disease is at all advanced free hydrochloric acid is entirely absent. Mucin and lactic acid are generally present. In a large number of cases of gastric carcinoma at St. Mary's Hospital, where a complete analysis has been made of the gastric contents, the active hydrochloric acid was in nearly every instance under 0·1 per cent. and the ferment activity was low (*vide* Table V.).

Remarks.—In all of these cases the diagnosis was confirmed by operation or necropsy.

The amount of active hydrochloric acid present depends on the site of the growth. In pyloric carcinoma the amount present is greater than when the cardiac portion of the stomach is involved. When the pyloric portion only of the stomach is involved often the total acidity is normal or even increased, but in these cases the active hydrochloric acid is almost always below 0·1 per cent., the difference between the two being due to the presence of much organic acids. A great difference between the total acidity and the active hydrochloric acid is very suggestive of pyloric carcinoma (*vide* Table V., Cases 6 and 16).

In cases presenting persistent gastric symptoms, with wasting and anæmia and a lump palpable in the region of the stomach, if there is a marked reduction of the active hydrochloric acid and ferment activity the diagnosis of gastric carcinoma is almost certain.

There is no doubt that in some cases of gastric carcinoma the growth develops on an old ulcer. These cases are likely to show in the early stages a larger amount of active hydrochloric acid than the usual type of case. It has been stated that the hydrochloric acid may in these cases be normal. In all the cases examined at St. Mary's Hospital there has, however, been a definite reduction of active hydrochloric acid and usually of the ferment activity.

Cases have been seen in which the active hydrochloric acid has been normal or above normal, and when after operation the lump present was thought to be a carcinoma of the stomach. In every one of such cases where there has been an opportunity of microscopical examination after necropsy the lump has proved to be an ulcer with inflammatory thickening around it.

In connexion with the marked diminution of active hydrochloric acid found in gastric carcinoma, the question naturally arises whether the diminution is due to a defective secretion of hydrochloric acid, or whether it is due to a neutralisation of acid by alkaline secretions from the carcinomatous tissue. The answer to this question is given by the results of analyses in the two conditions. In gastric carcinoma the mean of six recent analyses showed: active HCl, 0·05 per cent.; inorganic chlorides as sodium chloride, 0·26 per cent. While for gastric ulcer the mean of six recent analyses showed: active HCl, 0·24 per cent.; sodium chloride, 0·34 per cent. (*vide* Table VI.). Hence in gastric

carcinoma the cause of the diminution of hydrochloric acid cannot be due to neutralisation, for if it were the sodium chloride would be increased, whereas the reverse is the case. The diminution of hydrochloric acid must be due to defective secretion and is, no doubt, caused by the associated gastritis.

16. *Carcinoma of organs other than the stomach.*—Moore and Morton Palmer have shown that in some of these cases the free hydrochloric acid and the active hydrochloric acid are reduced. The reduction is not sufficiently great to be of diagnostic value, because an equal reduction occurs in many other conditions of ill-health. The analyses made of cases at St. Mary's Hospital have shown that frequently in carcinoma of other organs than the stomach the active hydrochloric acid has been normal in amount, even when the growth was contiguous to, but not involving, the stomach. In cases of carcinoma of the transverse colon where there has been a lump in the region of the stomach the presence of active hydrochloric acid and ferment activity in normal amount has been made use of in correctly diagnosing the seat of the growth as being in the colon and not in the stomach.

Children.[17]

17. *Congenital hypertrophic pyloric stenosis.*—Usually free hydrochloric acid was absent and the active hydrochloric acid much reduced. Mucin was always found present. The ferment activity was normal or raised.

18. *Pyloric spasm in children without thickening of the pylorus.*—In these cases the active hydrochloric acid was found to be normal, but the ferment activity was low.

19. *Marasmus.*—In these cases free hydrochloric acid was absent. The active hydrochloric acid and ferment activity were very low.

Illustrative Cases in which the Gastric Analysis was of Great Value in Diagnosis.

CASE 1.—The patient, a woman aged 56 years, had had marked gastric symptoms for several months, with wasting, anæmia, and a lump in the region of the stomach. Active HCl, 0·28 per cent.; free HCl was present. Gastro-enterostomy was done by Mr. V. Warren Low in 1906. The patient is alive and well and is quite relieved of all symptoms.

CASE 2.—The patient, a man aged 60 years, had had dyspeptic symptoms for some months, wasting, and a lump was felt in the epigastric region. The vomit contained 0·08 per cent. active HCl, with

[17] Willcox and Miller: On Some Gastric Conditions in Wasted Infants, THE LANCET, 1907, vol. ii., p. 1670.

normal ferment activity; stercobilin was present. The diagnosis of carcinoma of the colon, ulcerating through to the stomach, was confirmed by operation.

CASE 3.—The patient, a woman aged 38 years, had had severe gastric symptoms for six months, marked wasting and anæmia, with great weakness; a lump was felt in the epigastric region. Active HCl, 0·16 per cent.; ferment activity above normal. Operation showed an ulcer with much induration around. Gastro-enterostomy was performed in April, 1909. The patient was completely relieved of symptoms, with increase of 2 stones in weight.

CASE 4.—The patient, a man aged 45 years, was operated upon in 1901, when a large mass was found which was thought to be malignant and left untouched. In 1907 the patient presented himself for severe gastric symptoms. The active HCl was above normal, and free HCl was present. Gastro-enterostomy was done, but the patient afterwards died from pneumonia. Necropsy showed that the large mass was an old thickened ulcer with induration around.

CASE 5.—The patient, a man aged 63 years, had had dyspeptic symptoms for six months with much wasting and cachexia; a lump was present in the epigastric region. Active HCl, 0·22 per cent.; free HCl was present; the ferment activity was normal. The diagnosis of carcinoma of the transverse colon, with normal stomach, was confirmed by operation.

CASE 6.—The patient was a man, aged 57 years. In August, 1908, he was an in-patient at St. Mary's Hospital, complaining of gastric symptoms and wasting of five months' duration. Analysis showed active HCl 0·19 per cent.; free HCl was present; ferment activity was normal. He was relieved by medical treatment and left the hospital. In September, 1908, he went to another hospital, where an exploratory laparotomy was performed, and gastric carcinoma was suspected; nothing was done. In June, 1909, he again entered St. Mary's Hospital and a gastric analysis showed that the active HCl and ferment activity were above normal. A gastro-enterostomy was performed, and an indurated mass—no doubt a thickened ulcer—was felt. The patient has been completely relieved of symptoms and now weighs 20 pounds more than before operation.

In conclusion I wish to express my hearty thanks to all my colleagues at St. Mary's Hospital for the numerous opportunities given me of making the investigations on which this paper is based. I am greatly indebted to Mr. John Webster, demonstrator of chemical pathology at St. Mary's Hospital, for his valued assistance in the analytical portion of the work.

Welbeck-street, W.

ON ACUTE ARTHRITIS OF DOUBTFUL ORIGIN.

BY G. BURNSIDE BUCHANAN, M.B., C.M. GLASG., F.R.F.P.S. GLASG.,

ASSISTANT SURGEON TO THE WESTERN INFIRMARY, AND TO THE CANCER HOSPITAL, GLASGOW.

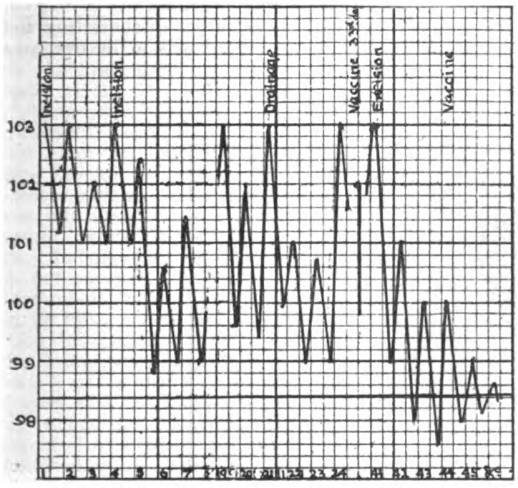
SINCE joints are so liable to pains and are so frequently subject to inflammation, whether accompanied by fever or not, and yet so commonly recover without any lasting defects, the more serious disorders are apt to be disregarded in making a diagnosis in the earliest stages of arthritis. Too often inflammation occurring in joints is labelled rheumatism, and valuable time is lost in temporising with salicylates. And it is to call attention to those conditions which, though not common, are probably less rare than a superficial examination might suggest, that the following cases are presented. In many of them the diagnosis at first was obscure, and in some indeed the actual pathological conditions were only determined at a late stage. It is easy, of course, to be wise after the event, but it is also easy to be led astray by a series of phenomena which do not conform to classical symptoms.

CASE 1.—A boy, aged 7 years, was admitted to hospital in November, 1907, with pain, swelling, redness, and heat over the left hip. He had been ill for four days, and was sent as a case of osteomyelitis. The temperature was 104° F., the pulse was 176, and the respirations were 40, and there was slight albuminuria. The child, who was extremely emaciated and looked very ill, with flushed face, sunken eyes, and profuse sweating, was suffering greatly and was constantly crying out in a state of delirium. Movement of the leg did not elicit any special pain, but the whole thigh was tender to the touch. The abdomen was retracted, rigid, and tender on pressure all over, but there was nothing further to indicate any abdominal disease, and this abdominal condition disappeared in a few days. Under chloroform an incision was made over the trochanter, where the swelling and œdema were most localised. As no sign of pus appeared a small gouge was driven well into the neck of the femur with negative results as regards the discovery of abscess. The soft tissues round about were explored with similar results, but the joint was not opened. The wound was drained by gauze packing and a dressing applied. On the suspicion of acute rheumatic fever sodium salicylate was administered. Within 24 hours a uniform bright-red rash developed all over the skin, and the tongue presented a striking "strawberry" appearance, but the other symptoms gave no real indication of scarlet fever, which it much resembled. This rash passed off in a few days and was followed by copious desquamation. The pain at first remained as before the operation, on the outside of the thigh, but after a few days it became more clearly localised in the knee. It was then surmised that the knee had become involved, but the pain was not elicited by movements of the patella or by flexion of the knee, and was so specially on moving the hip; and this was taken to indicate in the absence of sufficient local signs that the inflammatory irritation was in the hip-joint. Accordingly, the joint was aspirated, and this diagnosis was confirmed by the appearance of a small quantity of sero-purulent fluid, which gave a pure culture of staphylococcus aureus. Extension was applied with weight and pulley, and without further aspiration or drainage the inflammation gradually but slowly subsided, the joint never at any time showing swelling or distension; while the first wound closed up rapidly. The boy meanwhile improved in every way, and under the influence of generous feeding and malt and cod-liver oil, by the time of his dismissal he was bright and cheerful and quite fat. In February (77 days from admission) he was sent to a home in the country, with his limb in a Thomas's hip splint; there he remained till April in good health. The joint was fairly moveable and all swelling of the leg had disappeared, but it was considered advisable to limit the movements for some time longer. At this time there was one inch of shortening.

A skiagram taken in the month of May showed—(*a*) considerable atrophy of the head of the femur, and (*b*) thinning and excavation of the acetabulum. From this it is right to suspect the possibility of a primary osteomyelitis of the acetabulum, which will be discussed later. This idea is in some measure corroborated by the abdominal symptoms, previously very obscure, but possibly attributable to the nearness of the disease of the pelvic bones to the abdominal cavity.

This abdominal tenderness and rigidity were so pronounced that it was suspected at first to be due to peritonitis, but it subsided without going on to suppuration. Such inflammations of the peritoneum are recognised as occurring occasionally, though rarely, in association with eruptive fevers and with erysipelas. In the latter case it is usually purulent and almost always fatal; but excluding those cases which occur in the course of enteric fever and are due to rupture of an ulcer, some of the others are apparently rather of toxic than actual microbic nature. Rheumatic peritonitis is accepted as an entity by some authorities; Oettinger, [1] indeed, describes two forms, the one being primary and preceding the arthritis, and the other secondary and following about the sixth to the ninth day, though both are rare. But its very existence is disputed by others, Widal [2] amongst them expressing doubts in spite of published cases. As Allchin [3] says: "On general grounds a rheumatic peritonitis would appear to be highly probable, since inflammation of the serous membranes of the joints and of the pericardium are among the most frequent 'terms' of the 'rheumatic series.'" And after excluding all doubtful cases there still remain some in which a peritonitis of rapid onset, transient duration, and equally rapid disappearance occurs in association with well-marked arthritis and other accepted rheumatic phenomena; and such cases seemed to justify the assumption. In the above case it is likely that the symptoms were due to irritation of the membrane by the toxin, which was virulent and abundant enough to produce the very severe constitutional effects observed.

The next case was in many respects similar in onset, though more severe in its sequel.



CASE 2.—A girl, aged 15 years, was admitted to hospital in December 1907, with pain in the right hip. She had been ailing for four days, and was looking very ill, with high fever (temperature 103° F., pulse 124) and heavy sweating, and suffering intensely. On the previous day she had developed a rash all over the body, uniform in distribution and bright red in colour, and the tongue had a "strawberry" appearance. This disappeared in another 24 hours and was followed by copious desquamation. On examination of her limbs it was found that movements produced no exact pain, but there was an indefinite area of tenderness over the hip, with nothing else of note. A provisional diagnosis of osteomyelitis of the head of the femur was given.

The girl was anæsthetised, and an incision was made over the region of the trochanter; but no evidence of suppuration or even of inflammation appeared. A deep stab incision was then made into the joint, and though no purulent fluid was observed, a cultivation from the knife showed a pure growth of staphylococcus aureus. Thereafter the limb was put in extension and the pain subsided somewhat. A day or two later the pain shifted to the knee of the same side, and the joint was distended with effusion which lasted for a few days. Afterwards the ankle on the same side, and the knee and ankle of the opposite side, became affected in the same way, one after the other. On the eighteenth day, however, the old pain reappeared in the right hip-joint, and the signs of arthritis became quite definite. The fever, which had been irregular till then, now became more constant, and the joint showed swelling both in front and around the trochanter. A free incision was made and a drainage tube was inserted into the joint cavity. For a time this acted well, but the discharge never got away freely enough, so that it became necessary to excise the head of the femur and curette out the acetabulum. It was then found that by that time (44 days from the onset of the attack) the cartilage of the upper and posterior part of the head of the femur had become eroded, while the superficial part of the epiphyseal cancellous bone beneath this area was necrotic, the cartilage of the acetabulum also being eroded to a similar extent and the ligamentum teres being quite destroyed. Thereafter the wound was

drained with comparative ease, extension being applied to prevent undue displacement of the limb on the pelvis, and the girl's condition became greatly improved.

A vaccine had been prepared by Dr. J. Miller from a culture of the discharge from the wound, and several doses of this were given at intervals of ten days or so. The first coincided more or less with the last operation, and it may be that it helped in the general improvement which started at this time. Owing to Dr. Miller's illness the examination of the opsonic index was interrupted, so that it is difficult to apportion the benefit of the vaccine. Later on, however, a pain appeared in her back, with tenderness on pressure, accompanied by a little rise of temperature, on which another (the fourth) injection of vaccine was given. This was followed by complete relief and should be given the credit of it. The wound gradually closed, and after continuing the extension for some time to allow the parts to consolidate a little, the patient was allowed up on crutches, and was dismissed well to the country home. During her illness the heart sounds were normal throughout, and there were no symptoms of cardiac lesions.

FIG. 1.

CASE 2.—Shows effect on the temperature of operations and vaccines.

Investigation as to the primary focus of this infection was doubtful. There was no sore-throat nor pre-existing disease, but the tonsils were slightly enlarged and the teeth were in a shocking septic condition; the head also was covered with an eczematous eruption due to pediculosis. In all probability the source must be looked for in the teeth, especially as there was a slight thickening of the submaxillary glands, indicating irritation of some duration. No history of injury could be obtained, and the girl, who was not very intelligent and rather hysterical, could give no information on the subject.

In both of these cases the early symptoms had a resemblance to scarlet fever with joint complications, and in view of the danger to other children in the wards further consultation with colleagues with a wide fever hospital experience was asked, and scarlet fever was definitely excluded. The symptoms, moreover, were much more severe than are usually met with in scarlet fever unless of a virulent type. The questions of scarlatiniform rashes connected with acute inflammatory diseases and the administration of drugs, scarlet fever complicated by unusual symptoms, and the different conditions spoken of as "surgical scarlatina" have attracted a good deal of attention, but are too wide for discussion here. The rash in Case 1 was almost certainly induced by the salicylate exercising its effect on a body already abundantly toxic and producing no specific benefit on the subject. According to Morrow[4] this particular form of rash is unusual, but others are common enough as a result of exhibiting salicin and its compounds either by the mouth or on the surface of the skin. In Case 2 the rash was evidently a toxic one, corresponding in its nature very much to the first, but originating with the infective organisms.

The next case also presented appearances similar to the first two.

CASE 3.—A girl, aged seven years, was sent in to hospital as a case of osteomyelitis in February, 1908, with great pain down the left thigh, and tenderness on pressure, accompanied by fever and rigors. She had been suffering five days, and accounted for it by saying she had fallen off a swing some time before and had hurt her leg, which remained painful, however, for a very short time. The pain on admission was quite unlocalisable, but the tenderness seemed to be rather over the outside of the thigh. Movements of the hip and knee did not appreciably alter the pain, nor did pressure about the joints elicit complaint. The skin was not red and there was no œdema, but there seemed to be a little enlargement towards the middle third of the femur. And as this was the place always pointed to as the chief seat of pain, an incision was made down to the bone and a small trephine opening was made into the medulla; but no thickening of the periosteum or other structures was found, no pus was evacuated, and a cultivation from that region proved to be sterile. On the suspicion of the hip-joint being inflamed extension was applied to the leg.

The temperature fell a little after this, but still remained febrile; and on the ninth day of illness the pain in the knee was distinctly elicited by moving the hip, and there was tenderness on pressing in front of the joint. Next morning under chloroform the joint was aspirated, and a small quantity of sero-purulent fluid was removed, a cultivation of which gave a pure growth of staphylococcus aureus. The temperature fell for a day or two, but rose slightly as a pain appeared in the right shoulder. This disappeared, to be followed by a pain in the left wrist. By the thirteenth day there was a little suppuration of the original wound in the leg, with apparently some periostitis which gave rise to higher temperature for a few days; this probably arose from the patient passing urine in bed and thus contaminating the dressings and wound. Meanwhile, the hip and other joints had recovered almost completely, though a fresh pain arose in the right ankle, lasting for a day or so, but unaccompanied by fever. After the third week there was little further rise of temperature, and the wound healed up in the ordinary course. But there was still a little fulness of the right hip-joint, though no pain or tenderness.

About the end of the sixth week the extension weight was taken off the leg, but this was followed by a relapse characterised by a sharp rise of temperature, pain in the hip, and swelling about the joint, and the limb was found in the adducted and inwardly rotated position. The extension was renewed with gradually increasing weights until the limb was brought into proper position, and as the swelling still remained the joint was again aspirated, when a quantity of sero-purulent fluid was removed (giving on culture a pure growth of staphylococcus aureus). Thereafter the case progressed favourably, as before and after a further aspiration the synovitis subsided. But there was a considerable amount of fulness around the hip, and once or twice there was a little rise of temperature. An X ray stereogram taken at this time showed (*a*) an area of atrophy beneath the ossifying centre of the great trochanter, and (*b*) an irregular roughness of part of the head and neck, with (*c*) a general but slight atrophy (transparency) of the whole upper end of the bone when compared with the sound limb. Accordingly in May, on the suspicion of an abscess forming, an incision was made posterior to the great trochanter and a gouge was inserted into the area below it. The tissue removed seemed healthy, however, though rather wanting in cellular elements, somewhat resembling the condition of bone seen in periostitis albuminosa.[5] The soft tissues were not specially œdematous, and the joint which was tapped was not distended at all. The wounds were drained with iodoform gauze for a few days, after which they were allowed to heal up, the temperature meanwhile remaining about normal and the child's general condition excellent.

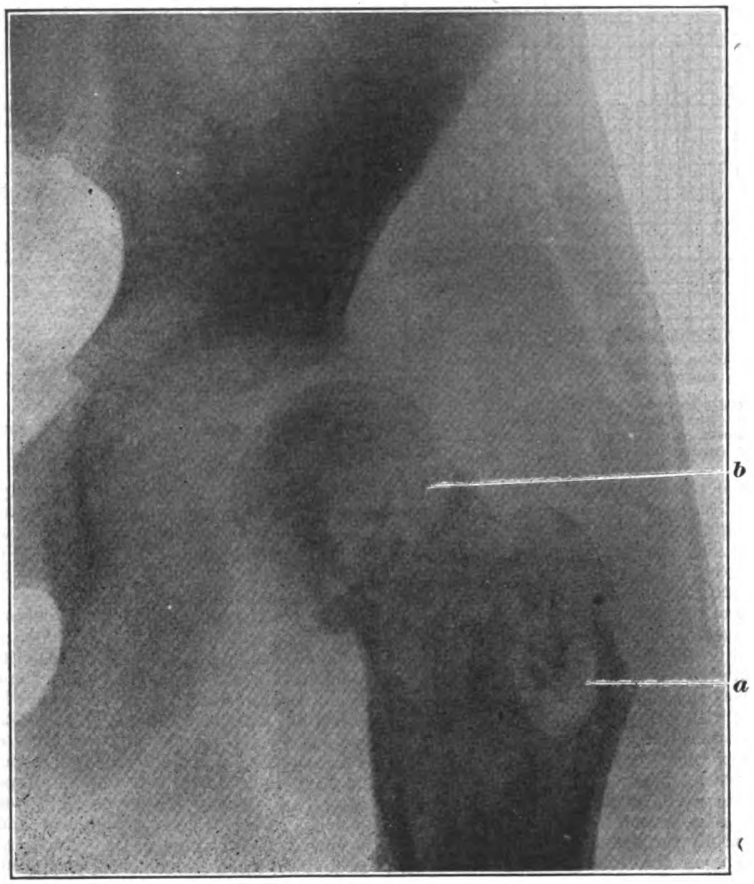
An examination of the possible sources of origin of this disease was quite inconclusive. The teeth were all sound and there was no history of intestinal or pulmonary ailment previously. The tonsils were certainly enlarged, prominent, and slightly cryptous, and the post-nasal adenoid tissue was rather well marked, but this was not obtrusive and was only discovered on minute examination. Nevertheless, it is probable that the site of entrance in this case may be looked for in the tonsillar tissue.

The diagnosis of these three cases in the earlier stages calls for special attention. All three showed a considerable resemblance to rheumatic fever: the sudden onset with high temperature and profuse sweating, the migratory tendency of the articular pains, with absence of pre-existing foci of infection, are characteristic of that disease. But there was an absence of redness and glaziness about the joints; the sour smell so commonly noticed in acute rheumatism was wanting in spite of the amount of perspiration; and even after careful examination no signs were observed of cardiac lesions; while rigors, which are unusual in rheumatism, occurred in all these cases. Further, the administration of salicylate, when it was used, produced no appreciable effect on the pains or temperature; and, though it would be idle to dogmatise on the subject[6] until further light is thrown on the organisms causing rheumatic fever, this absence of reaction to salicylate is at least very suggestive.[7] Moreover, young children are comparatively little subject to primary inflammation of joints; and even rheumatic fever, which is common enough in children, expends its virulence on the heart, lungs, or nervous system rather than on the joints, at least in much greater proportion than in adults.

Suppuration, too, in true rheumatism is very rare,[8] and according to some is practically unknown.[7] The pleurisy which sometimes complicates the disease usually causes a dry thickening,[9] and when empyema is found it is generally due to contamination with other microbes through the lungs; and even in cases of severe endocarditis with vegetations on the cardiac valves from which living organisms can be cultivated,[10] pyogenic foci are not found elsewhere as a result of its spread; on the contrary, these do give rise to nodules of cell infiltration and proliferation of the fibrous tissue throughout the body, especially in the subcutaneous tissues.[11] When suppuration does take place in the joints or elsewhere it is

due either to a mixed infection,[12] originating in the mouth, nose, tonsils, or intestinal tract, or it occurs in one of the pseudo-rheumatic diseases, as Widal classes them, and what was formerly described as "malignant rheumatism" was really most commonly osteomyelitis with joint involvement. In the cases under consideration the detection of the staphylococcus aureus at once negatived the idea of pure rheumatism, though at first it gave little further information.

As an example of rheumatic fever complicated by a mixed infection the following case may be cited.



CASE 4.—A girl, aged 13 years, was admitted to hospital in February, 1908, with swelling of the right leg and knee-joint, tenderness on pressure and extreme pain on movement, accompanied by fever and great prostration. Some weeks before the right knee had become suddenly painful and swollen, and the patient felt ill and was feverish. This was diagnosed as acute rheumatism and treated with salicylates. The inflammation gradually subsided in the joint, only to appear in several of the other joints—viz., the right and left ankles, left knee, and shoulders. When those joints had partially recovered the right knee again became affected and remained painful and swollen in spite of treatment. The medical man attending her remarked that the salicylates had little effect on the pain or temperature. During the last few days the leg became more acutely inflamed, with swelling and œdema of the whole limb, but without great redness of the skin. The girl's general condition also became much worse, and she was removed to hospital in the condition noted above, with a temperature of 103° F., and signs of extensive effusion about the knee.

Under anæsthesia the limb was cleansed and incisions were made into the knee at both sides. A large abscess was encountered lying over the patella, burrowing widely in the subcutaneous structures, and communicating directly with the joint, and from there spreading high up beneath the muscles, but no indication was found of implication of the bones. The pus was examined bacteriologically and gave a pure culture of staphylococcus citreus. Sufficient counter-openings were made to ensure drainage, and the cavities were flushed out with saline solution. The patient recovered from the anæsthetic, but during the afternoon she was seized with a sudden syncopal attack accompanied by an acute pain in the right side of the chest, and died almost at once.

Owing to the short period of her stay in hospital and the distance in the country of her people's home, it was difficult to get further particulars of her illness.

In the first three cases there was evidence also of osteomyelitis strong enough to justify the operations immediately undertaken. There were fever with high temperature, rapid pulse, rigors, sweating, and profound illness, in one instance actually typhoid in character. In addition there was pain in the region of the hip, vague in locality, but aching and persistent in character, and tenderness on pressure about the upper part of the thigh. But there was no evidence of arthritis at first either from thumping on the heels, from flexing or rotating the limb, or by distension of the joint with effusion. Further, in only two cases was there swelling or œdema, and in each it was rather disconcerting to find that beneath the [tumefactions presumed to lie over an area of osteomyelitis no such condition was found, and ultimately the actual foci of inflammation were found at some distance away.

FIG. 2.

CASE 3.—Shows (*a*) area of atrophy below great trochanter, and (*b*) at the head and neck.

Ever since Chassaignac's[13] observations on the association of the diseases of joints with osteomyelitis, arthritis as a result of bone disease in the vicinity of joints has been a well-recognised event; and this has been greatly illumined by the more recent work of T. Smith,[14] Volkmann,[15] Schede,[16] Müller,[17] Lexer,[18] and others.[19] And even coxitis from osteomyelitis at the upper end of the femur has attracted a considerable literature of its own. The reason of this distinction is, of course, the deep situation of the joint, which causes a variation in the physical signs of such inflammations compared with arthritis elsewhere in the body, thus producing a special symptom-complex for itself.

The most extensive records of this condition are those of

von Bruns and Honsell,[20] who reported 106 cases of their own, and of Guyot,[21] who has collected 54 others, including some of Lannelongue's[22] and Macnamara's[23]; but further contributions have been made by Jordan,[24] Pick,[25] and others,[26] making about 200 cases in all. Those papers will well repay perusal, but an excellent *résumé* is to be found in the German "System of Practical Surgery."[27]

It has been accepted by most of those surgeons that disease of the upper part of the femur above the level of the lesser trochanter, especially when it occurs in young children, should be considered for clinical purposes as "epiphyseal" in the broader sense of the term; partly on developmental grounds, as the head, neck, and both trochanters occupy at first only one cartilaginous epiphysis which is not completely differentiated at a fairly late stage of growth; and partly because the head, neck, and base of the trochanters all lie practically within the joint capsule. Now osteomyelitis of the epiphysis often remains circumscribed in certain foci for a considerably longer time than in the shafts; and it is hindered more or less by the epiphyseal cartilage from spreading beyond the junction lines; thus extension takes place where resistance is weakest—namely, into the joint, where it sets up arthritis, or along the bone beneath the periosteum, ultimately forming an abscess on breaking through. Inflammation of the true epiphysis (the head) alone is not common, and when it does take place it implies early invasion of the joint. But the head is often involved secondarily by extension from the neck or trochanter, or by its surface through suppuration in the joint cavity. In either case the ligamentum teres usually necroses early. The acetabular surface also becomes eroded; but it should be remembered that the disease may start in the pelvic bones, generally about the Y-cartilage, as indicated in a series of cases reported by Bardenheuer.[28] The osteomyelitis is more often followed by absorption of the bone than by thickening, and this predisposes to spontaneous fracture or dislocation, or to coxa vara and other late changes. Actual sequestra are not usually formed, but atrophic disintegration is more general, though occasionally the whole head is separated at the epiphyseal line. The accompanying arthritis varies from a mild catarrh to virulent purulent forms effecting widespread disorganisation. And the results vary in proportion, from complete restitution to firm ankylosis on the one hand, or destruction of the joint on the other.

From an analysis of the cases referred to the constitutional symptoms are found to be fairly uniform: sudden onset, with high temperature, rigors, headache, sometimes delirium, and occasionally a typhoid condition even at an early stage. While the local signs are given as pain referred to the hip or knee or even down the leg; tenderness on pressing on the trochanter or heel or at the base of Scarpa's triangle; muscular spasm fixing the joint, adduction and inward rotation of the limb, with swelling from œdema, abscess formation or distension of the joint, and redness or dilatation of the venules of the skin. Widal[29] says: "The intensity of the fever, the typhoid state of the patient, and the tumefaction and fluctuation around the region of the hip are sufficient to ensure of a rapid diagnosis." But it is just in the physical signs that the difficulty lies. Of all von Bruns's cases few were seen by him before the third week, and of these only one was noted as being without swelling. And in Guyot's, though he quotes several seen within the first 3-6 days, there was usually enough swelling or redness to suggest the nature of the disease; further, movement of the joint gave rise to pain and spasm in most of these, though in the absence of synovitis it is hard to explain why it should do so. In the "foudroyant" cases, however, the local signs were so overshadowed by the constitutional disturbance that the affection of the hip was lighted on only by accident. Von Bruns observes that the disease occasionally begins with a multiple arthritis, the inflammation subsiding spontaneously in all the joints but one, as in some of our cases, and he quotes four cases of his own in which that happened. At other times the disease subsides spontaneously only to break out again acutely in a few weeks or later.

From this it will be seen that diagnosis in the earliest stage is by no means so easy unless the condition is suspected and sought for. In the later stages the arthritic effusion or abscess formation gives clear indication of the state of the parts. In the cases which subside, however, it is only by a process of exclusion that they can be properly diagnosed from primary arthritis of other origin. By examination with X rays, however, not only can the foci of disintegration often be detected when they have been well established, but also alterations in shape resulting from the atrophy. As a rule, too, there seems to be a general translucency of the whole end of the bone, indicating a certain degree of porosis.

Prognosis in these cases is grave. The early stage is one of extreme danger from the liability of pyæmia following. Indeed, Kraske[30] maintains that osteomyelitis is no less than a form of pyæmia, and in this he has several supporters, but Pick[31] objects that the progress of osteomyelitis is so different from what we understand by pyæmia that this assertion cannot hold good. In any case, suppuration with disorganisation of the joint or abscess formation is the rule. And even if the attack should subside there is always a chance of recrudescence. In the later stages there are often deformity, spontaneous dislocation, and usually shortening with or without ankylosis or contractures. The mortality is high; von Bruns's cases, it is true, show only 15 deaths in 106, while Guyot, who by a strange misreading assumed that von Bruns related to chronic cases only, and therefore dismissed his statistics as foreign to his subject, records a mortality of 60 per cent., and of the 11 cases of Sir T. Smith 8 died.

But an examination of the details shows that the results vary with the treatment, and the same lesson is to be learned in all. When early operation and drainage are carried out the mortality is low and in some cases the disease is practically aborted; and when this is delayed there is usually abscess or even pyæmia, and in any case pronounced alteration in the structure and function of the joint. This entails an early recognition of the disease.

The following cases of arthritis arising from osteomyelitis in the vicinity of joints show the symptoms as they appear in typical cases where the diagnosis presents no great difficulty.

CASE 5.—A girl, aged 5 months, was admitted in February, 1908, with acute inflammation about the left shoulder. Four days before the mother had noticed that the shoulder was swollen a little; it was evidently painful, and she could not touch the arm without causing the child to cry. Three weeks previous to this the child had measles, from which she had recovered, except for a muco-purulent discharge from the left ear, which started about that time and was still continuing in hospital. On admission the child was seen to be very ill, pale, and highly fevered. The shoulder-joint was swollen, red, and fluctuant, but the discolouration and œdema did not extend down the arm. Movement of any degree obviously caused severe pain. There was no rash on the body. On the evening of admission the joint was incised in front and behind, and a tube was inserted between the openings, a large quantity of pus being evacuated from the joint cavity and from the head of the humerus (giving a culture of streptococcus). After the operation the baby showed no improvement; the temperature rose slowly, and ultimately on the following evening it reached 109·4° F., when the child died.

A much more fortunate case was the following.

CASE 6.—A boy, aged 11 months, was admitted in March, 1908, with swelling of the left shoulder, extreme pain on pressure at the head of the humerus, and high fever (temperature over 103° F.; pulse 120). The night before admission the mother had noticed that the child cried whenever the shoulder was touched or the arm was moved in the slightest degree, and he held the limb close to the side. There was no history of previous illness or injury, and the only focus of irritation discovered was a small pustule on the back of the left wrist of a few days' standing. On the day of admission an incision was made over the head of the humerus, and a small trephine was inserted into the cancellous tissue. No pus was evacuated, but the tissues were all highly vascular. The effect of the operation was rapid and striking: within 36 hours the temperature fell steadily to normal and remained thus to the end. The opening discharged a little serous fluid, which never reached a purulent condition and quickly healed up. The child left hospital very well, with the wound almost closed, and with free movement of the joint in the course of 10 days. A couple of months later the child was reported to be in excellent health.

The difference between these two cases is very striking, and the temperature charts show a remarkable contrast, but the explanation is obvious. On the one hand, a baby already disabled by measles and otitis is attacked with acute osteomyelitis and operated on after four days; on the other, a healthy child is attacked by the same disease, but observed and treated within 24 hours of the onset of the symptoms. In the second case the disease was evidently aborted, and the synovitis never got to the stage of suppuration.

CASE 7.—A girl, aged 6 years, was admitted to hospital with pain and swelling of the right elbow, and also with suppuration from the umbilicus, and a considerable degree of fever. Three weeks before, the child, who had always enjoyed the best of health, fell and bruised her elbow, but this did not cause much pain, nor apparently did it call for any special attention. A week later she was seized with a sudden illness, with sickness and vomiting, and diarrhœa, and after three days with suppuration from the umbilicus, the details of which need not be fully entered into here. But a few days after the right elbow began to swell and become painful. On admission—a week after the onset of the joint trouble—the elbow was swollen, hot and tender on pressure or

movement, and fixed by muscular spasm at about a right angle. There was considerable effusion into the joint, but no striking thickening of the ends of the bones. On the following day the joint was aspirated and found to contain fairly thick pus, so an incision was made and an ounce or so of pus was let out. On examination for the source of the arthritis an area of necrosis the size of a cherry-stone was exposed in the olecranon, and this was curetted out. A tube was placed in the joint, and Bier's band was applied for eight to ten hours at a time. The abdominal suppuration was found to be very extensive and connected with some intestinal suppuration. The child made little progress in hospital and was taken home in rather a precarious condition.

In the next case the relationship to the bone disease was still more obvious.

CASE 8.—A youth, aged 19 years, was admitted to hospital in January, 1908, with great pain and tenderness of the left leg, swelling and œdema from the foot up to the knee, and effusion in the ankle-joint, the skin over this part being red, tense, and glazed, and ill with fever, with a temperature of 102° F. This had begun with a slight bruise to his leg in the course of his work a week before admission, which at first did not cause him inconvenience, but next day produced stiffness and pain of the foot and ankle. After four days this had progressed so much that the limb became swollen and very painful, and the patient began to have rigors. As soon as possible after admission incisions were made into the soft tissues, and the tibia, which was widely necrotic, was freely opened. The ankle-joint was found to be suppurating, and as the inflammation was spreading to the foot, after a little delay to obtain parental authority, the leg was amputated. The boy made an excellent recovery.

Another interesting point in this patient's case is the fact that workmen's compensation was claimed and obtained from the insurance company. The question of such claims for osteomyelitis resulting from slight traumatisms is of importance in view of the wide distribution of liability created by recent enactments. According to Bloodgood [32] it has been settled in Germany that if the symptoms of osteomyelitis develop within 14 days after an injury it is just to assume that the trauma is a definite etiological factor, and practitioners in this country must be prepared for further claims of the sort requiring a medical report.

The pathology of juxta-epiphyseal osteomyelitis has been further elucidated by the researches and experiments of Lexer.[33] By his injections of the bones of young children he shows that there is a threefold blood-supply at the ends of the long bones, all of which terminate in fine capillaries which are only too liable to be the seat of microbic embolism. These blood-vessels are derived from (*a*) the main diaphyseal ("nutrient") artery as terminal branches near the epiphyseal cartilage; (*b*) from numerous metaphyseal branches entering the bone directly from twigs of the articular arteries at both sides of the epiphyseal line; and (*c*) from the epiphyseal branches also arising from the articular arteries by several branches and nourishing the articular surfaces. The second group is the most important, as the vessels are found supplying the areas most frequently the seat of pyogenic or tubercular infection. The older the bone the finer relatively become the arterioles, though all three groups can be demonstrated up to the period of full ossification. But at the same time the arterial supply of the joint apparatus becomes much more developed. These anatomical variations explain, as Bloodgood [34] points out, why bone lesions are most common in infancy and youth, while joint lesions are more frequent in the adult.

A contrast to those cases may be seen in the next case.

CASE 9.—A girl, aged 18 years, was admitted to hospital with swelling of the leg around and below the knee of eight days' duration, resulting from the penetration of a needle into the skin about the level of the tubercle of the tibia 11 days before. On the supposition that the knee-joint was infected an aspirating needle was inserted at the outer side, far away from the swelling, but it withdrew only clear and sterile fluid On incising the soft parts over the swelling a large abscess was evacuated reaching down to the surface of the tibia, which was already necrotic and permeated with pus. This progressed so badly that the joint eventually became invaded, and ultimately amputation of the thigh was required. After a long convalescence the girl made a good recovery. Here the disease started from the outside, beginning as a cellulitis, next continuing as periostitis, then true osteomyelitis, which at last burst into the joint.

The following case presented more the features of gonorrhœal arthritis from the insidious beginning, the persistence of the subacute stage with feeble attempts at healing, and the stiffness around the joint without widespread suppuration in the tissues. The possibility of infection was gone into carefully by discreet inquiries of both wife and husband without throwing any positive light on the case; no discharge from the genital organs was ever detected, and examination of the fluids from the wound never revealed the presence of gonococci. The resemblance to acute rheumatism was sufficient to admit of her being treated at first for that disease; but the symptoms ultimately resolved themselves into a uni-articular arthritis with some slight temporary synovitis of other joints.

CASE 10.—A married woman, aged 27 years, was admitted in October, 1907, with synovitis of the left ankle. She had just landed with her husband from a transatlantic voyage, during which her ankle had become much worse after being painful for five weeks. The toe of the right foot had been swollen and tender a week before admission, but had recovered in a few days. She was ill and feverish, with pain in the joint and general redness all round it. She was a pale, thin, and rather nervous woman, never very strong, but not subject to any special ailments. There had been no history of any previous inflammatory trouble to account for a primary focus of infection. Under fomentation the synovitis subsided, but meanwhile there was a slight attack of the left wrist lasting for a day or two. The temperature ranged from 97° to 100° F. She was transferred to a medical ward, where she was treated with anti-rheumatic remedies; but after a few days she was sent back with distinct swelling about the joint, redness and œdema, and signs of threatening cellulitis, the temperature being 103° F. The joint was opened freely, and drained of a sero-purulent fluid, which gave a pure culture of streptococcus pyogenes. Thereafter drainage was continued, and a Bier's band was applied daily for several weeks, at first for 22 hours, but latterly for two hours a day. Ultimately (in ten weeks) the discharge dried up, and the patient was dismissed with the foot in a plaster casing, the joint being partially ankylosed.

In this case the application of Bier's bandage did not seem to influence the progress of matters much, either in respect of the time of healing or of the character of the discharge, though it is possible that it may yet have a conservative effect in the ultimate function of the limb. This negative result with streptococcic infections is quite in accordance with the experience of Bier [35] and others.

In true gonorrhœal arthritis the temperature, as a rule, is but little raised, and suppuration is generally scanty in amount. Though it often begins as a multiple arthritis it usually settles in one joint ultimately, for preference in the knee (about 75 per cent.), while the ankle is less frequently attacked (about 20 per cent.). It is also very chronic in character and does not yield to salicylate treatment. And the disease, though beginning with fluid effusion, seems to expend itself in the formation of fibrous tissue, causing thickening of the synovial membrane and the periarticular structures. Indeed, König [36] says that this is a symptom peculiar to no other disease of the kind, and that ankylosis occurring in a short time should always lead to the suspicion of gonorrhœa as a source of the arthritis. The absence of gonococci and the finding of streptococci in this case does not, of course, absolutely negative its gonorrhœal origin; but without confirmatory signs there is no justification for this assumption, and the disease must remain meanwhile unexplained.

Another case of mono-arthritis occurred.

CASE 11.—A boy, aged 12 years, was admitted to hospital in November, 1907, with swelling of the right knee, pain and limitation of movement, and effusion sufficient to cause floating of the patella. His temperature was 103° F., pulse 110, and respirations 40. 12 days before he had been attacked with pneumonia implicating the left lung, and a distinct crisis had occurred six days after. At the time of his admission the lung was still partially consolidated, but gave signs of clearing from day to day. There were abundant pneumococci in the sputum. The knee was treated by fixation in splints and warm fomentations were applied to relieve the pain; but as it was considered inadvisable to open the joint it was aspirated. The pathologist reported that the fluid, which was sero-purulent, contained streptococcus in pure culture. The synovitis subsided in the course of a few days without further treatment than the application of Bier's bandage for a time. Shortly afterwards the boy complained of a tender spot at the inner side of the thigh just about the insertion of the adductor magnus. As the temperature tended to rise again at this time (from 98°–102°) an incision was made down to the bone, but no pus was found, and cultivation from the vicinity proved sterile. Notwithstanding this, after a few days of relief from pain and fever, the pain and swelling occurred again almost at the same spot. This time a drachm or so of pus was evacuated, giving a growth of streptococcus and staphylococcus on culture; but as the bone showed no sign of involvement it was not opened. The general symptoms again improved and the abscess soon closed up. But the temperature once more rose with irregular intermissions, and the cough reappeared to a certain extent. An examination of the lung showed a considerable amount of effusion in the left pleural cavity. This was withdrawn and a tube was inserted, a piece of the ninth rib being removed for the purpose. After a day or two the evacuation was aided by the use of Bier's cupping glasses applied for an aggregate time of half an hour a day. After several weeks the discharge gradually dried up, and the patient was dismissed well to a home in the country.

This might be regarded as a pneumonic arthritis had not the bacteriological report rendered it doubtful; and the negative result was confirmed by the absence of pneumococci in the periostitic fluid. Now that that the true nature of pneumonia is recognised quite a large number of cases of pneumococcic arthritis has been collected; and a series of them has been cited and discussed by Cave,[37] who further refers to several instances of primary arthritis of pneumonic origin, which either preceded an attack of pneumonia as

reported by Pasteur and Courtland,[38] or even were never followed by any disease of the lungs at all as recorded by Griffon,[39] and Widal and Meslay.[40] In these the diagnosis was made on the bacteriological findings. The results, for the most part, are said to be very grave, both as regards mortality and, in non-fatal cases, destruction of the joints. In this case possibly the synovitis should be looked upon as an accidental inflammation set up by a mixed infection, doubtless originating in the lungs, and induced by the predisposition caused by the attack of pneumonia. Were all cases of synovitis associated with pneumonia subjected to a bacterial examination, probably many would be found to be of this nature.

The next is a case of synovitis without suppuration occurring in the course of an acute infection.

CASE 12.—A boy, aged 13 years, was recovering from osteomyelitis (from staphylococcus aureus) of both tibias, followed by abscesses on the scalp and the buttock, doubtless pyæmic in nature. When the acute stages had all subsided the sterno-clavicular joint one day became swollen and tender, while the temperature rose a little. The synovitis never went on to suppuration, but subsided in a few days without any special treatment of any kind. Whether micro-organisms were present in the joint or not was never determined, as circumstances did not warrant exploration with the aspirator.

This synovitis corresponds with that seen in the previous cases (Nos. 2, 3, and 4) occurring in the earlier parts of the diseases. Assuming that it is actually caused by micro-organisms and not by toxins only in the joint, it is still easy to see how likely this is to occur if microbes are circulating in the blood. For Chvostek[41] shows by his experiments that organisms often may be recovered from the synovial fluids a few hours after they have been injected into the blood stream, and that without any appearance of damage to the synovial membrane either on inspection or by microscopical examination. And Hofbauer[42] points out that this exudation is specially determined there by the exceedingly rich blood-supply of the synovial fringes. Should the joint be injured in any way it is still more natural to expect synovitis. Indeed, it is remarkable how seldom in the aggregate that synovitis occurs as a complication of acute diseases. The same rich blood-supply may be assumed to help in the elimination of such microbes, though absorption from joints is always proportionately much slower than effusion.

For comparison with the others a case of frankly septic arthritis from direct infection may be adduced.

CASE 13.—A man, aged 46 years, was admitted in October, 1907, with suppurating arthritis of the left knee. 16 days before he had cut into the joint with an adze, and this accident was followed in three days by pain, swelling, and effusion of a yellowish fluid from the opening. At the time of admission he was suffering from pyrexia, with rigors, sweats, delirium at night, and all the signs of acute toxæmia. The knee was much swollen, œdematous, and tender on pressure, the joint was distended with fluid, and the patella was "floating." There was a trickle of sero-purulent fluid (yielding staphylococcus aureus on culture) exuding from a small wound at the side of the patella.

The joint was widely incised at both sides, and irrigated with saline solution. Several pockets of pus were found burrowing into the adjacent muscles and other tissues both in front and behind, and these were freely exposed and drained. After the tendency to bleed had stopped a Bier's bandage was applied daily, at first for 16 hours or so but later for less; but it did not appear to affect the local condition except by increasing the amount of effusion, while the general symptoms remained as before. The band therefore was left off after ten days or so, as it always caused some discomfort. These conditions remained without much change in spite of further exposure and drainage. And after about eight weeks there was so much destruction of the joint and its surrounding structures, with dislocation of the bones, starting pains and tenderness, accompanied by loss of flesh, nightly delirium, and other constitutional effects, that it was manifest that no more progress could be expected; accordingly the limb was amputated at the middle of the thigh. The wound healed well, but took a considerable time owing to suppuration from contiguity of various septic foci; and convalescence was also delayed by the presence of a large bed-sore which appeared in spite of careful nursing.

Why this case should be so malignant compared with the preceding ones is not at once clear, as the organisms were the same as in many of the others. The real explanation rests mainly on the mechanical difficulty of draining the knee-joint owing to its complicated shape and the tendency for pus to form pockets at the back. Flint[43] has collated the experience of a number of surgeons on septic infection of the knee, and from the 310 cases reported he has deduced the conclusions that penetrating wounds of the knee mostly become septic (about 60 per cent.), and in these the mortality is high (over 13 per cent.), and nearly all the non-fatal cases result in great functional disability. This being so, if the joint is to be opened and drained at all, the first operation should be radical and extreme, and probably the safest operation for virulent cases is to make an incision across the knee, dividing the patella in two and keeping the knee acutely flexed, so that the joint remains exposed and can be drained by packing in every corner, as recommended by many surgeons. Milder cases can, of course, be dealt with by less radical measures.

In many of the foregoing cases it will be seen that the source of infection is doubtful, for, with the exception of Cases 9 and 13, no special focus was definitely recognised. In some of them the buccal cavity was suspected, since it is now acknowledged to be the starting-point of many ailments, as has been well demonstrated by Hunter[44] and others.[45] But numerous other sources of inflammation have been reported in connexion with arthritis and osteomyelitis. Amongst those besides the various acute fevers, such as influenza,[46] enteric fever,[47] and those previously referred to, may be mentioned suppuration of the umbilical cord in infants,[48] puerperal discharges of various kinds from the mother,[49] bronchiectasis[50] and whooping-cough,[51] appendicitis,[52] dysentery[53] and other intestinal troubles, and cutaneous inflammations such as ulcers,[54] wounds,[55] vaccination,[56] and other eruptions. Fraenkel[57] has shown that bacteria are frequently disseminated and localised in the bone marrow during all acute infectious diseases, and that they may live there for weeks or months; and later, after a slight injury, excite advanced pathological changes which are quickly manifested clinically as local osteomyelitis. And this applies equally to accidental or mixed infections associated with those diseases. As Bloodgood[58] remarks, this explains the difficulty experienced in most cases of osteomyelitis in establishing an etiological factor of recent date, because the interval between the primary infectious disease and the local signs of inflammation is long. In only two of our cases (Nos. 3 and 8) were the traumatic influences marked enough to draw attention to them, in spite of keen investigation about them all. But as young children are so apt to get small injuries from tumbling about, it is almost certain that most had some traumatic origin. In the absence of injury, however, nerve influence alone is sufficient to induce a localised inflammation, and in the older patients this should not be overlooked. This is clearly evidenced by the experiences of Widal,[59] who observed arthritis in a limb affected by lead palsy when the other joints were free; and the experiments of Hermann[60] and Kasparek[61] show that arthritis may be artificially induced after an injection of toxic bacteria by cutting the nerve which supplies the joint observed.

For the purpose of diagnosis X rays are very valuable, and may reveal lesions which are unsuspected. They may also afford grounds for predicting subsequent shortening or deformity of the bones, and this, of course, aids prognosis.

Treatment of these acute forms of arthritis resolves itself into rest and relief of pressure: the first hindering further preventable trauma, and the second restricting the absorption of toxins into the general system, and this is, of course, carried out by the use of splints or extension. Further relief is obtained by aspiration, which in the mildest cases is sufficient. The employment of tubes for drainage is requisite in the pyogenic cases, for although it is objected that in sero-purulent conditions they are apt to induce fibrous thickening and subsequent ankylosis, in the severe cases this will take place at any rate. If drainage cannot be adequately maintained in this way part of the joint should be resected to prevent pocketing of pus, and this is specially called for in arthritis of the hip, when the head of the femur often requires excision. In the desperate cases an early amputation is sometimes the safest and most logical treatment.

Of the two newer aids to therapeutics—Bier's hyperæmia and Wright's opsonic vaccination—a certain amount of doubt still remains. Bier[62] speaks enthusiastically of the effect of hyperæmia on traumatic and other arthritis, and I had the opportunity a short time ago of seeing some of his successful results in Bonn. But my own experiences[63] of it, in joint diseases at least, have been disappointing; in six or seven cases there has been little improvement. But other surgeons[63] corroborate Bier's opinion by favourable reports of their own cases.

Of the opsonic treatment in acute disease it is still less easy to give an opinion, whatever its value may be in chronic conditions. It is permissible to attribute some improvement to it in Case 2, and I have seen some benefit in other cases—viz., septic spinal disease commencing with tuberculosis, and similar mixed infections, treated with cultures made from the

discharge. It is claimed with some justice that aspiration of an infective fluid causes a flow of serum rich in opsonins into the space evacuated, and also that Bier and Klapp's cupping glasses used in connexion with sinuses have a similar effect. But out of a series of papers on the opsonic treatment which has lately appeared [64] little light has been thrown on the application of it to acute conditions, and much wider experience is necessary before a definite judgment can be pronounced.

ROYAL COLLEGE OF SURGEONS IN IRELAND.—The following is the list of prizes awarded for the winter session, 1909–10. Systematic Anatomy: D. J. Flanagan, first prize (£2) and medal; G. E. Pepper, second prize (£1) and certificate. Descriptive Anatomy: W. I. Adams, first prize (£2) and medal; D. J. Flanagan, second prize (£1) and certificate. Practical Anatomy: First year: W. Morrow, first prize (£2) and medal; R. A. Austin, second prize (£1) and certificate. Second year: G. C. Sproule, first prize (£2) and medal; W. I. Adams and G. E. Pepper (equal), second prize (£1) and certificate. Practice of Medicine: J. T. Duncan, first prize (£2) and medal; T. M. Thomson, second prize (£1) and certificate. Surgery: J. T. Duncan first prize (£2) and medal; F. Warren, second prize (£1) and certificate. Midwifery: J. T. Duncan, first prize (£2) and medal; M. S. Moore, second prize (£1) and certificate. Physiology: J. D. Cherry, first prize (£2) and medal; A. F. Patterson, second prize (£1) and certificate. Chemistry: J. Lanigan, first prize (£2) and medal; L. E. Wigoder, second prize (£1) and certificate. Pathology: Vernon J. White, first prize (£2) and medal; T. T. Buckley, second prize (£1) and certificate. Physics: A Merrin, first prize (£2) and medal; L. E. Wigoder, second prize (£1) and certificate. The summer session commenced on April 4th.

A NEW METHOD OF TREATING ACUTE PHTHISIS BY THE ALTERNATE USE OF HUMAN AND BOVINE TUBERCULIN.[1]

BY H. WARREN CROWE, M.D. OXON.

VACCINE therapy as practised to-day is difficult. Whether inoculations are administered by the empirical method it is difficult, or under the control of the opsonic index it is also difficult—difficult not only in the technique but also in the interpretation. In phthisis it is probably more difficult than in any other disease caused by bacterial invasion, and the more active the disease the greater this difficulty.

If we are asked wherein the difficulty chiefly lies we should be candid in replying that it lies in the avoidance of doing harm.

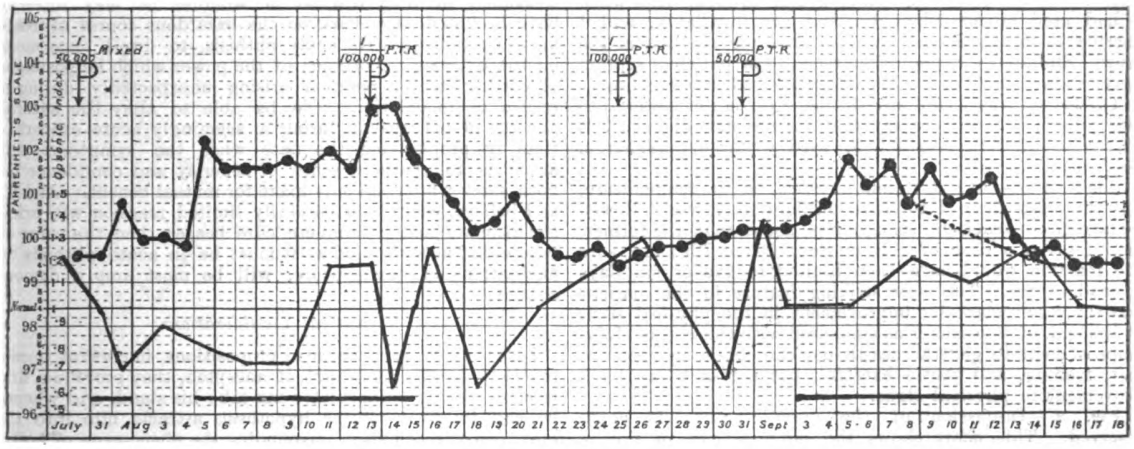
It is impossible to disguise the fact that tuberculin may do harm. If after a dose of tuberculin a rise of temperature occurs, accompanied by malaise, increased sputum, increased physical signs, and a disproportionately quickened pulse, and lasting for a fortnight or even longer, one cannot deny that the inoculation may have done harm. Yet I venture to suggest that this result has not infrequently followed doses of T.R. even so small as 1/100,000th milligramme. I would go further and say that in active phthisis, with a rectal temperature ranging above 100° F., a further rise of temperature, commencing sooner or later and lasting a longer or a shorter time, is the most usual result of the smallest efficient dose of tuberculin. But if tuberculin does good in acute cases—and many will, I think, be found to bear witness to its value—and if it be granted that a rise of temperature usually results from small yet efficient doses of tuberculin, it follows that the rise of temperature is not necessarily an unfavourable symptom. Obviously the length of time that the rise is maintained is the determining factor in the result of the dose, whether it shall be for good or whether it shall be for ill.

An unprejudiced observer will readily acknowledge the good effect of a dose of tuberculin if it result in a rise of temperature lasting two or three days, followed by a fall to a point below the average range preceding the dose, and if then the temperature range remains at the lower level, whereas he will undoubtedly condemn as harmful treatment an inoculation which apparently causes a rise of temperature with accompanying discomfort lasting a fortnight or longer.

Now it is quite impossible in acute phthisis to anticipate the effect of any dose with certainty (with one exception which will shortly be stated). 1/100,000th milligramme T.R. may have no effect the first time, but if repeated even this minute dose may provoke a prolonged reaction. It is a usual experience when re-commencing inoculations with a minimal dose after a period of cessation, due possibly to the patient's intolerance—fancied or real—to find oneself faced at the onset by a prolonged and distressing reaction. And though it is quite conceivable that an increased vigour in the protective mechanism is the cause of the phenomenon, yet it is discouraging to the physician and terrifying to the patient and his friends. If now it were possible to devise a method whereby such an awkward reaction could be cut short tuberculin administration in acute phthisis would be shorn of half its terrors. Wright advocates a minimal dose being given if the "negative phase" be too prolonged—if, that is to say, the dose causing that phase has been too large—but this method does not always meet with success in phthisis, and if the reaction we wish to stop be caused by 1/100,000th milligramme, what conceivable dose must we employ to check it?

I have now to describe a method whereby a prolonged reaction can be cut short with almost absolute certainty—even an obvious overdose can be prevented from doing harm and may not infrequently be turned to good account.

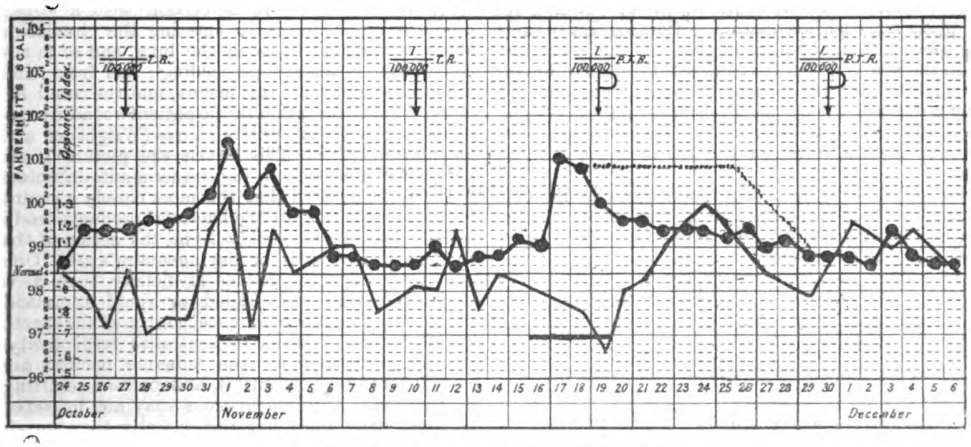
It is maintained by some observers that there is a very real difference between the strain of tubercle bacilli grown from the human disease and that grown from the disease as found in cattle, the typus humanus and the typus bovinus; further, that human beings can be infected by either strain,



[1] The tuberculin referred to is T.R. and its bovine equivalent P.T.R. (from the German "Perlsucht" = Bovine tuberculosis).

cattle usually only by their own specific type. Further, that in using tuberculin in the human subject an attempt should be made to determine the origin of the infecting organism and the appropriate vaccine then given. If both types are present, as is said to occur commonly in phthisis, then a mixed tuberculin should be employed. As a refinement of this it has been suggested, again, that should reactions of marked intensity follow inoculations by a tuberculin of homologous type, the alternative or heterologous vaccine may be used with advantage. Dr. Nathan Raw advocates the "opposing vaccine" being always used, as he maintains that its curative power is greater, since it antagonises and neutralises the autogenous "tuberculin" formed

Since it is my belief, which I trust this paper will tend to justify, that the "cure" (as opposed to the "arrest") of the disease in its acute form is impossible without febrile reactions, and since the voluntary induction of a rise of temperature carries with it the responsibility for any harm which may result from such a rise being too prolonged, the great value of a reliable method for terminating at will such a "therapeutic tuberculin reaction" will be immediately apparent. I have, as far as possible, emphasised this interesting phenomenon, as upon its proper application rests the success of the method for the inoculation of acute phthisis now to be described.



A start is made by an inoculation of 1/100,000th milli-

FIG. 1.

Inoculations are shown by the combined letter and arrow, the T in the sign indicating T.R., and the P., P.T.R. The first inoculation was a mixture of T.R. and P.T.R., hence the sign. The beaded line indicates the temperature. (In all the charts the temperature record represents the evening 9 P.M. temperature only—an excellent graphic method which I adopted after reading E. C. Hort's "Rational Immunisation in the Treatment of Pulmonary Tuberculosis.") The plain line shows the opsonic curve. Days of malaise, increased sputum, and physical signs are shown by broad horizontal base line. The dotted line suggests the probable course of the temperature had 1/100,000th milligramme T.R. been administered on Sept. 6th or 7th. In Fig. 2, on the other hand, the dotted line indicates probable temperature had 1/100,000th milligramme P.T.R. on Nov. 19th been omitted.

FIG. 2.

Same patient as in Fig. 1. Further progress of case.

at the lesion. I find it difficult to subscribe to this hypothesis.

Without entering further on the various methods in use, and the even more various hypotheses propounded in connexion therewith, I can speak unhesitatingly of the great value of using these two forms of tuberculin in an alternating fashion. Briefly, I have found that a prolonged reaction resulting from the use of either of them can be cut short by a dose of the other provided that there has been developed some degree of hypersensitiveness to the form of tuberculin which excites the reaction

gramme of either T.R. (or P.T.R. in the most acute cases, as it appears slightly less liable than the former to cause acute reactions). This dose is repeated and gradually increased once every 7 to 10 days until a definite febrile reaction is provoked, accompanied by signs of an exacerbation in the disease, malaise, &c. The reaction may not appear for three or even six days after an inoculation, hence the interval between the doses. This rise of temperature is allowed to continue until it seems to be steady at the higher level or until the physical condition of the patient causes alarm, when a dose of P.T.R., half the quantity of the exciting dose

of T.R. (but not as a rule less than 1/100,000th milligramme), is inoculated. The next day the temperature may remain up, but the day after at latest it will fall, and after a few days there will be found to be a definite improvement in the physical condition of the patient and also in the local lesion. This inhibitory dose is the exception above referred to. It is now advisable to rest for a time, say a fortnight or until the temperature has again risen, when the same dose of P.T.R. must be repeated and gradually increased, until for a second time a febrile reaction is induced, when it will be found that a dose of T.R. will now have the effect of cutting short the P.T.R. reaction.

Fig. 1.—Disregarding for the moment the opsonic curve, this chart shows so well a reaction accompanied by high temperature cut short by P.T.R. that I insert it here, although the exciting dose was a mixture of T.R. and P.T.R. I have found the same action of P.T.R. in other cases when I had used mixed tuberculin, but not invariably, and I ascribe it to the actual breed of tubercle bacillus in the lung. Stained by Spengler's method, this patient's sputum never showed any but the human type of tubercle bacillus.

The reason why I used mixed tuberculin is not material to this paper; suffice it to say that I have now discarded it in favour of T.R. and P.T.R. used separately as herein described.

The next dose of P.T.R. had no effect on the temperature, but the third dose, 1/50,000th milligramme, was followed by a definite reaction, though less acute than the former. Had I given a dose of T.R. on Sept. 6th or 7th I feel sure the reaction would have been limited to five or six days instead of ten. The most striking feature in this patient was the very remarkable improvement in the physical signs at the end of September as compared with the end of July. Improvement in general health one can obtain by open air, rest, feeding, and gentle exercise, but not such rapid improvement in physical signs.

Fig. 2.—Discussion of the opsonic curve is again reserved. This chart shows the same scheme of dosage continued. The patient is the same as in Fig. 1. A period of six weeks was allowed to pass after the last reaction before inoculations of tuberculin were resumed. During this "off time" the health improved, the temperature was but seldom above 99° F., the patient was walking daily, but the physical signs remained stationary. I have omitted, for the sake of clearness, certain doses of second organism vaccines, given sometimes with the tuberculin, sometimes alone. Their effect was difficult to adjudge, but, on the whole, the resulting tendency was to a lower range of temperature and less sputum. Microscopically there was to be seen a numerical reduction of the secondary organisms in the sputum. On Dec. 9th a third dose of bovine tuberculin (1/100,000th milligramme) was given and was followed by a distinct though mild reaction (highest evening temperature 100·2°). A certain hypersensitiveness had clearly developed as a result of the repeated inoculations with P.T.R.

The following notes of a somewhat more chronic case (evening temperature in reactions 101° F. maximum, at other times ranging between 98·6° and 100°) provide a more extended view of the treatment.

Date.	Dose.	Remarks.
1909.		
Sept. 3rd	1/100,000th milligramme P.T.R.	No reaction.
,, 8th	1/50,000th ,, ,,	Slight reaction.
,, 20th	1/100,000th ,, ,,	No reaction.
,, 28th	1/50,000th ,, ,,	Marked reaction continued until the next dose.
Oct. 5th	1/100,000th milligramme T.R.	Temperature fell.
,, 28th	1/100,000th ,, ,,	No reaction.
Nov. 5th	1/50,000th ,, ,,	Short but sharp reaction.
,, 11th	1/100,000th milligramme P.T.R.	No reaction.
,, 30th	1/100,000th ,, ,,	Very slight reaction.
Dec. 7th	1/50,000th ,, ,,	Short but sharp reaction.
,, 17th	1/100,000th milligramme T.R.	No reaction.

The inoculations were accompanied by steady improvement. It will be noted that after a marked reaction, even though short, a change in the vaccine is made.

It is plain from a consideration of Figs. 1 and 2, and the notes of the chronic case, that after a series of inoculations of one form of tuberculin—T.R. or P.T.R. as the case may be—a reaction develops as the result of hypersensitiveness, and that this reaction may be terminated by an inoculation of the other form. These two central facts will, I am convinced, be amply confirmed on extended trial; but whether the doses I have indicated are the most efficient, either during the sensitising process or for cutting short the reaction, I prefer to leave *sub judice*. I certainly would hope that my present practice, as set forth above, may be gradually improved upon, though I believe that if rigidly adhered to it will be found to embody a greater measure of safety than has as yet been obtainable.

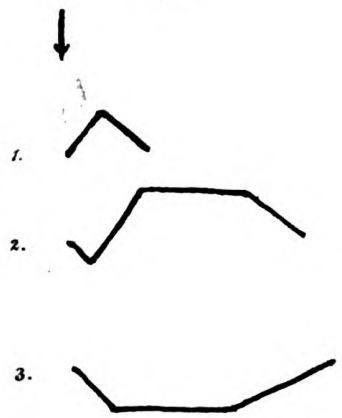
Before touching on any theoretical consideration I would first ask the medical reader, whether he specialises in the treatment of lung disease or whether he may hitherto have hesitated to embark on the hazardous course of treatment by tuberculin in acute phthisis, to dwell once more on the extreme importance of the power which he possesses of cutting short a reaction arising unexpectedly during a course of inoculations. To be able to allay the natural anxiety of his patient during a seemingly acute exacerbation by prophesying the date when the symptoms will abate is to create a sense of security and confidence on both sides which can only make for mutual benefit. And if, as I believe, each such carefully limited reaction will bring the ultimate goal of complete cure nearer, then the value of tuberculin, accompanied as it must be in acute phthisis by fluctuations of temperature, will be most amply demonstrated.

Theoretical Considerations.

I would now advance three propositions, important from a practical standpoint in that, if accepted, they provide a firm base on which the inoculator can take his stand, and whence he can follow whatever hypothesis attracts him into the labyrinth of speculation surrounding the phenomena of active immunisation.

1. *Auto-inoculations theoretically must have a greater curative action than therapeutic inoculations of tuberculin in the treatment of phthisis (whether acute or chronic).*—I am using this word auto-inoculations in the generally accepted sense—that is, as connoting the sum total of products, poisonous to the human organism, including quite probably living germs, which by any means whatever are made to leave the focus of infection and enter the general blood or lymphatic systems. It is certain that a stream of such products must always be entering the circulation from an active tubercular focus in the lung, and so in a sense auto-inoculation is always proceeding; but from time to time something more than this occurs, and the result is a definite recognisable fluctuation in the patient's condition, comparable to the negative and positive phases (Wright) of a therapeutic inoculation curve. This last is the picture I wish to bring before the mind when using the term auto-inoculation.

It will be granted that the more closely a vacine conforms in its constitution to the bacterial products produced in the lesion, the more efficient will be the action of that vaccine, for this is the basis of the inoculator's art. Obviously one can never hope to produce artificially such a vaccine so perfectly mixed and graded as would stimulate the production by the immunising mechanism of the exact proportion of antibodies required to neutralise respectively bacterial poisons, elaborated by the tubercle bacillus and possibly several secondary organisms, and poisons resulting from cell destruction. Auto-inoculations may not be safe, they may be most dangerous, but theoretically they provide a more perfect vaccine than tuberculin even combined with other vaccines.



Space will not permit me to do more than mention Paterson's magnificent results at Frimley through the systematic adoption of auto-inoculation in afebrile cases, or Hort's suggestion to use a spirometer for the production of auto-inoculation when fever prevents exercise. Both these observers are undoubtedly firm believers in the correctness of my first proposition.

2. *Tuberculin treatment causes hyperæmia at the lesion.*—This is generally accepted; I would refer the reader to Roepke and Bandelier ("Tuberculin in Diagnosis and Treatment"). Now Wright, Freeman, and many others have proved that hyperæmia is a cause of auto-inoculation. The more vascular a tissue in which a lesion is situated the more easily

will hyperæmia result in auto-inoculation. Lung tissue is *par excellence* the site where auto-inoculation could most easily be induced by a condition of hyperæmia. My third proposition may therefore in theory be accepted with confidence.

3. *Inoculations of tuberculin cause auto-inoculation.*[2]—This proposition leads us on to somewhat new ground. It certainly suggests a new conception. It would be necessary to modify the dictum, "A therapeutic inoculation must be safer than an auto-inoculation, because the former is a measured dose of dead germs and the latter an unmeasured dose of possibly live ones!" As a matter of fact, the amount of auto-inoculation which follows a dose of tuberculin does very greatly depend on the dose administered, and since this can be varied to some extent we can control the process; but it also depends, as a few moments of consideration will convince us, on the area of lung which is diseased, and again

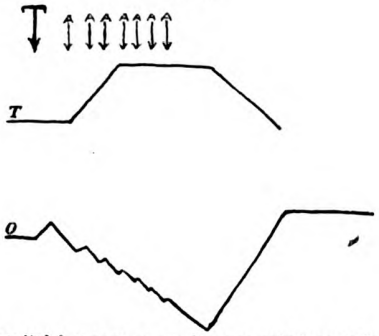


FIG. 3.

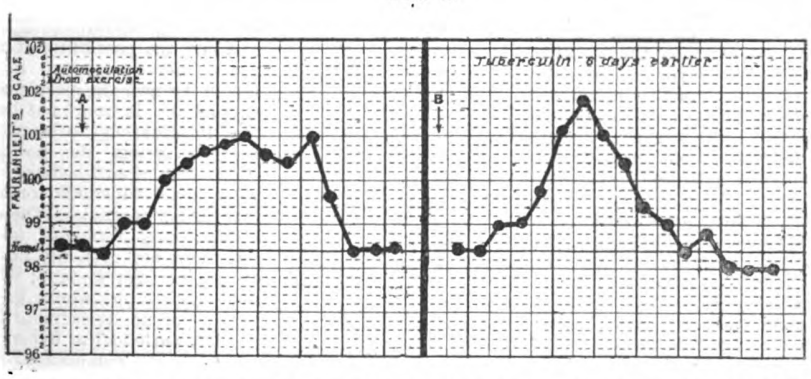
on the sensitiveness of the organism to tuberculin—a sensitiveness which is gradually developed through repetition of equal doses. It will be agreed that if auto-inoculations are an advantage in the treatment of febrile phthisis, as they undoubtedly are in chronic, and if tuberculin can cause auto-inoculation, then tuberculin would be a most convenient method of administering the necessary stimulus. Proposition 3, then, seems of some importance. I therefore propose to examine what evidence can be found to bear on the subject.

We should expect to find that until the effect of a therapeutic dose of tuberculin had entirely disappeared the clinical and bacteriological picture could be interpreted rationally by supposing the existence of a double wave of immunity instead of a single one—a wave due to tuberculin, followed sooner or later by a wave due to auto-inoculation, a primary wave, and a secondary wave. Since the amount of hyperæmia depends to some extent on the size of the dose—it comes on quicker and is more intense the larger the dose—we should expect to find that the larger the dose the more rapidly would the secondary wave appear, and the more quickly would it obscure the proper course of the primary wave. It is plain then that, except after minute doses of tuberculin, with an immunity curve (Wright) lasting only a few days, could the primary and secondary curve be separate and distinct, as a rule a superimposition of the latter on the former would take place. The primary and secondary waves

FIG. 4.



A capital A over an arrow shows an auto-inoculation.

should appear both in the clinical picture and also in the immunity curve as defined by the opsonic index. It will be agreed that the secondary wave is likely in active febrile phthisis to be a very great deal larger than the primary wave, and more especially so when we are dealing with minute doses of tuberculin. We should not be surprised to find that the primary wave clinically was only just recognisable; the secondary, on the other hand, strongly marked, whilst the immunity curve of the primary and secondary waves might approximate respectively to Wright's first and last schematic figures (Fig. 3).

Hitherto, for simplicity, we have regarded an auto-inoculation as a single definite occurrence, like an inoculation of tuberculin. Obviously this is not a correct view; it should be regarded rather as a rapid series of inoculations, small or larger, as the case may be, forming one continuous whole. Taking the temperature as a guide to the clinical condition and the opsonic curve to represent the immunity we might expect to find something of this kind (Fig. 4).

Again, we ought to find a close resemblance between the secondary wave (when separated from the primary) and an auto-inoculation the result of excessive exertion (Fig. 5).

FIG. 5.

Shows the similarity between an auto-inoculation curve due to exercise and one due to hyperæmia set up by tuberculin.

Let us first, for the sake of argument, assume its correctness—then let us consider what we should expect to find happening as the result of a dose of tuberculin. Lastly, let us examine actual results and see how they compare with the theoretical.

[2] Note that in these propositions (2 and 3) I am careful to avoid dogmatising on the effect of one inoculation of tuberculin, for it usually requires more than one dose to produce any appreciable hyperæmia when the doses are small.

Finally, it might be supposed that if during a prolonged negative phase occurring as the result of the secondary wave a minimal dose of tuberculin could be given, which would not further increase the hyperæmia, then a positive phase might be immediately brought on.

Let us now see how far the facts compare with the theoretical deductions.

Fig. 6 shows the effect of tuberculin in three different degrees. Schematically we may represent them as shown in Figs. 7 A, 7 B, and 7 C.

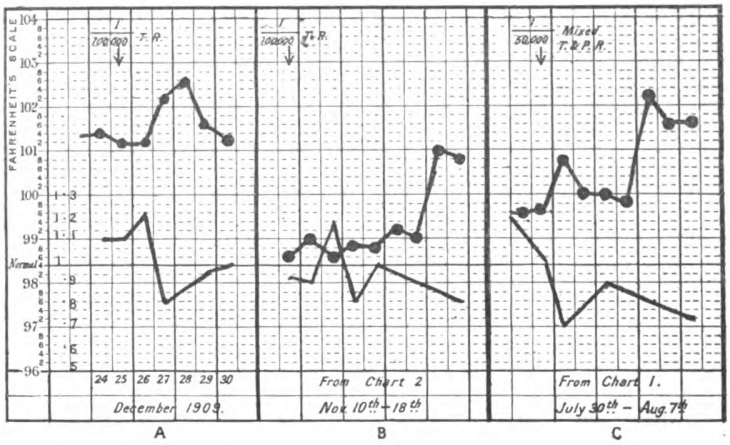
In A the primary wave is very short, and is not recognisable clinically; then follows the negative phase of the secondary wave.

In B, which is taken from Fig. 2, Nov. 10–18, there is a more fully developed primary wave also complete. As the immunity curve begins to rise after the drop at the end of the positive phase it is suddenly checked by the advent of the negative phase of the secondary wave. Turn for one moment to Fig. 2, Nov. 17th *et seq.*, and see the further development of this wave; it continues to show a prolonged negative phase until a dose of bovine tuberculin given on the 19th apparently brings about a typical positive phase. It is probable that the bovine tuberculin did not cause any increased hyperæmia.

In C, taken from Fig. 1, July 30th to August 7th, the primary wave is only just commencing; it is, in fact, only nearing the end of the negative phase; then the negative phase of the secondary wave is suddenly superimposed. Clinically the picture is equally plain: first two days of malaise following the dose, then three days of amelioration; lastly, a prolonged and distressing reaction. Here, then, the facts coincide very well with the theory.

Further rather striking confirmation is afforded by the next schema. This represents very closely the chart of a case of afebrile phthisis which I inoculated some two years ago, with doses varying from 1/10,000th to 1/6500th milligramme T.R. (modern reckoning). The temperature was steadily normal during the course except on two occasions—the first when I omitted a dose whilst away on a holiday and the second some 17 days after the last dose was given (Fig. 8). One can plainly see the primary and secondary waves distinct, the secondary curve is stepped and suggests that auto-inoculation is a process taking time.

If the truth of these propositions be admitted as far as they relate to acute phthisis, it is certainly probable that also in afebrile cases the chief value of tuberculin lies in the auto-inoculations induced by the hyperæmia. I will not further enlarge on the point, save by suggesting the possibility that this principle may be found to underlie many of the phenomena associated with the exploitation of vaccines other than tuberculin.



There still remain the questions: (1) of the causation of the hyperæmia; (2) of the development of hypersensibility or "anaphylaxis"; and (3) of the inhibitory action of a different form of tuberculin.

Many theories have been advanced to account for this hyperæmia, none entirely satisfactory. For details I would refer the reader to Emery's "Immunity and Specific Therapy." I cannot but think that the authors of these various explanations had in their mind the central nervous system as the immediate agent in the production of the hyperæmia, for it is almost incredible that pathological hyperæmia should differ in its origin so entirely from physiological hyperæmia as to arise independently altogether of nerve control. But no suggestion seems to have been definitely brought forward as yet that an afferent nerve, a nerve cell, and an efferent nerve are integral and necessary parts of the phenomenon. Yet surely it must be so, and although it may be possible to cut out the afferent nerve by presupposing a direct stimulation of a nerve centre by the circulating poisons in the blood, yet this does not materially affect the position.

Admit the possibility of collaboration by the central nervous system in the production of immunity and the problem certainly becomes simplified. It would not be greatly stretching the imagination to ascribe to the central nervous system the power of causing the elaboration of anti-bodies, whether in response to artificial tuberculin or to autogenous auto-inoculation products. The elaboration of HCl, alkalis, most ferments, and various internal secretions are certainly under control of the central nervous system; why not antibodies? But whether one would go to such a length or no, it is more than probable that pathological hyperæmia is the result of nerve stimulation.

One would regard a prolonged reaction following tuberculin as a vicious circle wherein, firstly, the central nervous system, stimulated either directly or indirectly through some afferent nerve by the artificial tuberculin, produces a hyperæmia. Secondly, the hyperæmia gives rise to auto-inoculations, of which the products in turn evoke increased hyperæmia, and so on. Whilst all the time nature is striving to produce a sufficiency of antibodies, to combine with all the toxic

FIG. 6.

Showing effect of tuberculin in three different degrees.

FIG. 7 A.

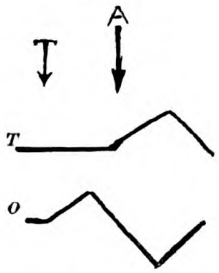


FIG. 7 B.

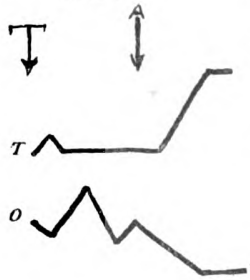

FIG. 7 C.

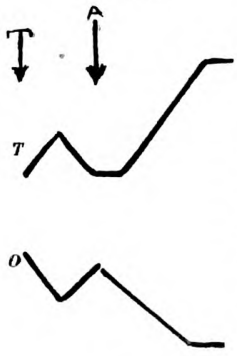

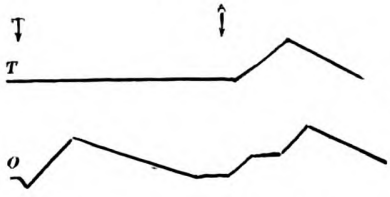

FIG. 8.

substances formed during this period. At last she is successful and the circle is broken, for the auto-inoculation products become neutralised as soon as they are formed and before they are able to further stimulate the central nervous system. The hyperæmia subsides and the reaction is at an end.

It must be admitted that artificial tuberculin probably differs very considerably in constitution from the product of the tubercle bacillus grown in the human system; hence at its first introduction the central nervous system may not recognise it as akin to the enemy within the lung. Therefore, no stimulus is provided to increase the hyperæmia at the lesion, yet at the same time antibodies must be produced to meet the new element now in the system, and though these antibodies may differ from those already under process of manufacture, yet there may be sufficient similarity to turn the scale against the products of auto-inoculation, and thus we can account for an improvement after the first dose. Exaggerated reactions may follow later doses, as the central nervous system gradually learns to associate tuberculin with the products of the disease which has attacked the system. In like manner, if a savage were to hear the dinner bell for the first time it would convey to him no meaning, but after he found that it preceded a meal, then at the third or fourth time of hearing the welcome sound his central nervous system would have become educated to its significance, and would set in motion the elaborate mechanism of digestion. An application of the same idea is all that is required to explain the action of bovine tuberculin in cutting short an auto-inoculation. Again a different product; to complete the simile it rings a different bell.

Tuberculin, then, would have a two-fold action. It always must excite the production of anti-tuberculin, it sometimes may also stimulate the central nervous system.

To sum up: 1. On general principles auto-inoculations should have a greater effect in influencing the course of phthisis for good than artificial tuberculin, that is, regarding tuberculin merely as an agent which stimulates the system to produce antibodies. 2. But tuberculin itself, if not at first, after repeated doses, causes auto-inoculation. 3. Tuberculin provides an easy method of inducing auto-inoculation in acute phthisis. 4. Auto-inoculations are dangerous in acute phthisis if they be too prolonged in their effect. 5. The power to stop an auto-inoculation at will diminishes this danger. 6. By using T.R. and P.T.R. in an alternating fashion, whilst the patient becomes sensitised to the one form, the power to prevent mischief is vested in the other, and on a continuance of inoculations of that other the inhibitory action is transferred to the former. 7. For a full development of this inhibitory action hypersensibility should be developed, hence small doses should be used because an auto-inoculation effect after the first dose or two is not desirable. 8. That the central nervous system may possibly play an important part in the processes of immunisation.

Yelverton, Devon.

THE TREATMENT OF GRAVES'S DISEASE WITH THE MILK OF THYROIDLESS GOATS.

BY WALTER EDMUNDS, M.A., M.B., M.C. CANTAB., F.R.C.S. ENG.,

SURGEON TO THE PRINCE OF WALES'S GENERAL HOSPITAL, TOTTENHAM.

A REPORT on this method of treatment was made two years ago[1] and again one year ago[2]; the present communication continues the previously recorded cases and adds others.

Of Case 1 nothing more has been heard; Case 2 is said to remain in good health; Case 3 is important because severe, and therefore a severe test. During the latter half of 1907 the patient took the milk from a thyroidless goat, and again during the whole of the summer of 1908; throughout 1909 there was given the dried whipped blood from a thyroidless goat, but early in 1910 it was found to cause diarrhœa, and was therefore stopped. During the whole of this time the patient was, as she still is, seriously ill, and was for a considerable period confined to her bed; the goitre is large, the pulse frequent; there are also exophthalmos and occasional attacks of dyspnœa at night. There is no evidence that the specific treatment by rodagen, by milk from thyroidless goats, or by dried blood from them was of any benefit in this case. Of Case 4 there is no further information.

CASE 5.—During the early part of the summer of 1909 this patient again had the goat's milk, and in June, 1909, commenced X ray treatment to the thyroid, the applications being at first twice, then once a week. She also took thyroidectin when the milk-supply failed. In November she was again admitted to hospital for a short time. She is now much better; the eyes are less prominent, she herself is less nervous, and the goitre is much smaller; it can now be distinguished into two separate soft lateral lobes and a central lobe, hard and tender; the diminution in the size of the goitre seems to be due to the X ray treatment.

Of Cases 6, 7, 8, and 9 nothing more has been seen. Case 10 was seen again in October, 1909; she is better than she was; the goitre is not very large, but is still obvious; it is firm to pressure; the eyes are still prominent.

CASE 11.—Early in 1909 a thyroidless goat was given to this patient, and she took its milk from April to December, 1909. She now considers herself much better in every way than she has been for years; she sleeps better; she is subject to attacks of palpitation about once a fortnight, generally at night; they last about half an hour; she says her heart is much better. The eyes are very little prominent, but the lids do not follow the globe down; the throat is much smaller; pulse 80.

Of Cases 12, 13, 14, and 15 there is no further information.

The following four cases are additional.

CASE 16.—Male, aged 34 years. The symptoms commenced early in 1908, but the patient did not seek advice until November of that year, when he was found to be suffering from fairly typical Graves's disease. He was treated with rodagen, but he did not improve; indeed, he became worse. He was then given thyroidectin, which he thinks does him good and which he therefore continues to take. In March, 1909, a consultation was held on the case and it was advised that the patient for three months should give up his work and rest in bed, having at the same time the milk of a thyroidless goat. Under this treatment the patient got much better, though he lost weight. After three months he went to the seaside and stopped the goat's milk; a month later he returned and resumed his work. He has now regained his weight and is in good health. The throat is of about the same size, but the eyes are no longer markedly prominent.

CASE 17.—A single woman. The symptoms commenced six years ago. In the spring of 1909 she was seriously ill with Graves's disease; pulse 145, attacks of dyspnœa at night, and a large goitre. She was treated with the milk from a thyroidless goat for four and a half months and also took rodagen. She greatly improved.

CASE 18.—A married woman, aged 28 years. She was admitted to hospital in May, 1909; obvious exophthalmos, pulse 120, thyroid uniformly and distinctly enlarged but not greatly so, tremors in hands. She was treated with milk from thyroidless goats, having from 35 to 40 ounces a day. When she left the hospital in two and a half months' time she was much better. In February, 1910, she was not so well and was readmitted. There is still obvious exophthalmos.

CASE 19.—A single woman, aged 24 years. The Graves's disease commenced four or five years ago; 18 months ago it was worse than at present (May, 1909), when this note was taken: "Pulse is 140; there is a uniform enlargement of the thyroid gland; there is also slight but distinct exophthalmos; it has been more marked than at present." During the summer of 1909 the patient took the milk of three thyroidless goats which had been operated on for her by her medical man, having for part of the time as much as two quarts a day; by September she felt herself much better; the exophthalmos was not so noticeable as in May and the goitre was smaller.

In the winter of 1908–09 I supplied some thyroidless goats to Dr. J. R. Gilmour of the West Riding Asylum, Scalebor Park, who tried the treatment on cases of Graves's disease under his care on account of mental symptoms, and has published his results.[3] In two cases there was considerable improvement, and in a third complete recovery. This last

case is especially interesting; there had already been improvement following the administration of Morbius's anti-thyroid serum.

"At the end of January," Dr. Gilmour reports, "we were able to begin the milk from thyroidless goats, and within a fortnight there was again an improvement. The pulse-rate declined to 88, and the mental symptoms ceased. Accidentally, we had to stop the milk for about ten days, and during this time the goitre again became prominent, and the symptoms showed signs of returning. During each exacerbation diplopia was present and troublesome. About the third week in February she had the entire milk-supply from one goat, and rapid improvement set in. The goitre diminished. She became very cheerful, happy, and contented. The pulse-rate fell to 64 per minute. The points of interest in this case are the very marked variation which occurred in the thyroid gland coincident with the use of anti-thyroid remedies, and the accompanying improvement of the mental symptoms."

Devonshire-place, W.

A CASE OF "TYPHOID SPINE."

BY E. ROCK CARLING, M.B., B.S. LOND., F.R.C.S. ENG.,
SURGEON, SEAMEN'S HOSPITAL, GREENWICH; ASSISTANT SURGEON, WESTMINSTER HOSPITAL, ETC.;
AND
L. R. KING, M.R.C.S. ENG., L.R.C.P. LOND.

A BOY, aged 15 years, was admitted from the *Arethusa* to the Seamen's Hospital, Greenwich, under the care of Sir William Bennett on Oct. 25th, 1909. Dr. C. G. Pugh, medical officer of health of Southend-on-Sea, gave the following particulars of the boy's illness:—

"He arrived in the borough on a day trip on July 9th; he had for several days felt ill, although he had not declared himself 'sick,' as he was anxious not to miss the day excursion. During the afternoon he became worse, complained of abdominal pain, was feverish, and was consequently admitted to the local voluntary hospital with a diagnosis of appendicitis. His condition not improving, laparotomy was performed on the following day, his appendix being removed. On July 13th I was asked to see him in consultation with the visiting surgeon as his symptoms pointed to the possibility of his illness being enteric fever. His spleen was enlarged, he had a few doubtful spots, and he was passing typical pea-soupy stools. His blood giving a good Widal reaction, he was on July 14th admitted to the borough sanatorium as a case of enteric fever.

His temperature fell gradually and became normal on July 20th. During the intervening period he continued to pass pea-soupy stools, some of which contained sloughs, and upon one occasion he had slight hæmorrhage from the bowel. On July 26th his temperature again became raised, a slight fulness could be felt above the pubes, and he complained of a frequent desire to go to stool. Upon rectal examination I felt a large swelling bulging into the right side of the rectum just below the brim of the pelvis. The surgeon who had operated previously was called in consultation, and as on the 29th of July the rectal swelling had become more marked and softer, while the fulness above the pubes was increased, he decided to perform laparotomy again. He made an incision in the mid-line, gradually broke down the adhesions between the subjacent coils of small intestine, and came upon a tense collection of fluid, just below the brim of the pelvis on the right side; the fluid, which proved to be turbid but not very offensive, was evacuated, and a drainage tube inserted. On the following day the temperature fell to normal; the discharge from the tube soon diminished, so that by August 26th the wound was superficial. The boy was discharged apparently well on Sept. 4th, the wound being healed."

The lad returned to his training ship, the *Arethusa*, and remained well till early in October, when he began to complain of pain in the back, for which he was put to bed on the 11th and sent to hospital a fortnight later. He was able to walk without pain, but it hurt him to bend his back. He appeared well-nourished. Beyond the scars of recent operations the abdomen showed nothing abnormal. The spleen could not be felt, though there was slight tenderness below the left costal margin. Upon examination of the back the spines of the eleventh and twelfth dorsal and first lumbar vertebræ were seen to be prominent, whilst there was a deviation of the column to the right from the level of the disc between the twelfth dorsal and first lumbar, compensated by a very gentle curve with concavity to the left in the upper dorsal region. The prominent spines were tender to percussion. Pain was elicited by jarring the spine as a whole and by pressure on the outer ends of the two lowest ribs. The knee-jerks and ankle-jerks were decidedly brisk, but the plantar reflex was flexor, and there was no disturbance of sensation. The spine was rigid in the whole lumbar and lower dorsal regions. On stooping down he was obliged to help himself upright by his hands on his thighs. There was no rotation below the cervical region. The temperature on admission was 99° F., and on the 28th it rose to 101·2°; he complained of "starting pains" which were immediately relieved by weight extension. On Nov. 2nd Dr. J. J. Braxton Hicks reported: "Widal reaction positive; microscopic method, dilution 1—30, in half an hour; sedimentation method, flocculi appearing at the end of three hours." This reaction was still to be obtained in February, 1910.

The progress of the case was steady but slow. The temperature was never seriously raised, but was a little above normal, with an occasional sharp rise of a couple of degrees. By the end of January the prominence of the spines had disappeared and a considerable degree of mobility had returned. No thickening was palpable on the dorsal aspect of the column. An X-ray photograph taken on Oct. 27th showed a very dense shadow over the bodies of the ninth, tenth, and eleventh dorsal vertebræ, extending laterally beyond their limits and expanding from above downwards to a point an inch outside the articular process on the right side and rather less on the left. The right edge of this shadow was rectilinear and well defined; the left edge was irregular and not so well defined below. Three weeks later a radiogram showed similar appearances but with modifications. The main mass of shadow was less dense, whilst indications of a localisation to the costo-vertebral articulations could be made out.

The interpretation of these radiographic appearances is by no means easy, but considered in conjunction with the clinical signs it may be taken to indicate a perfectly definite local lesion, in all probability an effusion beneath the periosteum or the anterior and lateral ligaments and around the costal joints. Very little new bone formation has resulted, and the maintenance of extension has permitted almost complete rectification of the deformity. There is strong presumption that the lesion was a spondylitis or para-spondylitis due to the bacillus typhosus.

Recent papers by Neisser,[1] Lord[2] (analysis of 26 cases), Fluss,[3] McCrae,[4] and Halpenny[5] have expanded our knowledge of the condition, and in particular have relegated the ideas which formerly prevailed as to the neurotic basis to their proper symptomatic limitations. Halpenny gives a bibliography of some 90 numbers and collates 73 cases. Briefly, his analysis shows that the majority of cases occur between the age of 20 and 35 years; males predominate (83 per cent.). The onset may be sudden (10 cases) or insidious (39 cases), is often determined by trauma, and occurs during convalescence in two-thirds of the instances; the lumbar region is by far the commonest site. Pain may be so severe as to require morphia or even chloroform; fever is not always present. Deformity is mentioned in the reports of 23 patients; in a few instances there have been signs of pressure on nerve-roots and in others of changes in the cord. Very few cases have been operated upon, and it is not clear that in any instance a pure typhoid osteomyelitis of the vertebral bodies was demonstrated. It is of interest, however, to recall that Quincke and Stuhler found the bacillus typhosus in the rib marrow of eight out of nine fatal cases, and that Fraenkel in all of ten cases found the bacilli in the cancellous tissue of the vertebræ, the greatest numbers being present in the lumbar region. The duration, as stated in 34 cases, is usually from three to five months, but one of two years is recorded. Mention of non-recurrence is made in 58 reports. X-ray examinations appear to have been made in 11 cases; in one

or two nothing abnormal has been found. For the most part, new bone filling in the intervertebral spaces or in the lateral ligament, or definite synostosis has been indicated. A case reported by Silver is described thus: "..... On the right the lateral borders of the two vertebral bodies formed an unbroken line; on the left there was an irregular shadow projecting outward between the transverse processes," and seems to correspond to our case.

A NOTE ON THE MINUTE STRUCTURE OF THE THYROID GLAND.

BY D. CHALMERS WATSON, M.D. EDIN., F.R.C.P. EDIN.,
ASSISTANT PHYSICIAN, ROYAL INFIRMARY, EDINBURGH.

IN the course of an investigation into the effects of varying diets on the structure of the tissues and organs in tame rats, my attention has incidentally been directed to the varying histological appearances of the thyroid gland in wild rats. The examination of the thyroid gland in a series of 40 wild rats, all apparently healthy, has shown wide variations in the histological appearances of this gland. This point is one of considerable interest, and, so far as I am aware, attention has not previously been directed to it. The source from which the animals were obtained was noted in all instances, the rats being caught in such diverse places as a sewer, a hotel basement, outhouses of an asylum, railway station, a canal bank, and a bird shop. The weights of the rats ranged 60 to 370 grammes, 20 of the number weighing 200 grammes and upwards. As it was observed that the histological appearances of the gland in quite young animals were not strikingly different from those of the fully grown subjects in the same series it is assumed that the differences in the histological appearances to be described are not directly associated with the age of the animal, and accordingly no further differentiation will be made between the condition of the gland in young and adult subjects.

Histological appearances.—The microscopic appearances of the gland vary considerably. In many glands the vesicles are large and full of colloid, which takes a very delicate pink stain with the hæmotoxylin and eosin stain; a few of the vesicles may be empty or may contain a clear watery secretion. The secreting cells lining the vesicles are flat in character and consist of a darkly stained nucleus with a very small amount of protoplasm in the body of the cell, the nucleus occupying the entire breadth of the cell. There is a relatively small amount of intervesicular glandular tissue. Blood-vessels are inconspicuous. Fig. 2 illustrates another type of gland which differs from the first chiefly in presenting a more cellular appearance and containing less colloid; as in the former instance, the colloid may be stained a delicate pink or may have no affinity for the hæmatoxylin and eosin stain. Blood-vessels are prominent. On high power examination the secreting cells are of a low columnar or cubical shape, the nucleus being of a moderate size and circular shape, and occupying the entire breadth of the cell. There is a moderate amount of intervesicular glandular tissue, the nuclei in these cells being considerably larger than those of the cells lining the vesicles. There are also glands intermediate in structure between those represented in Figs. 1 and 2 respectively. The appearances represented in these figures were present in 31 of the series of 40 animals; in 26 out of the 31 the type of gland was similar to that shown in Fig. 1.

FIG. 1.

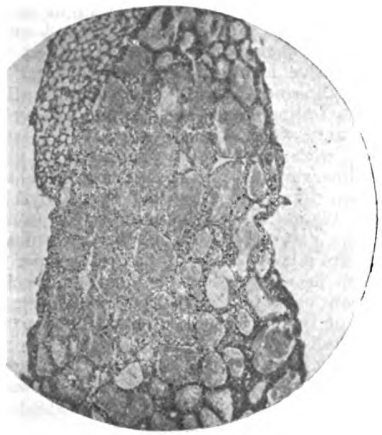

FIG. 2.

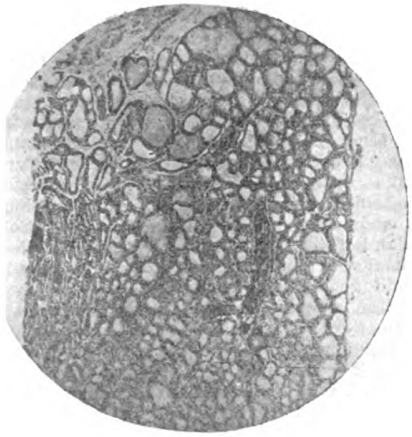

FIG. 3.

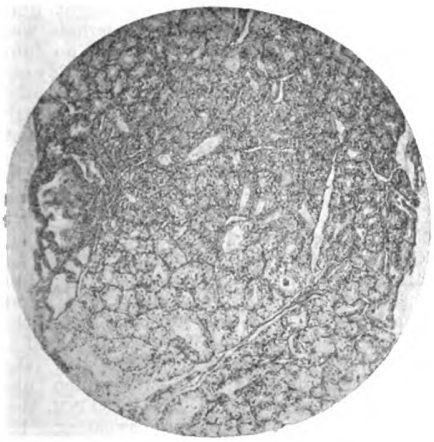

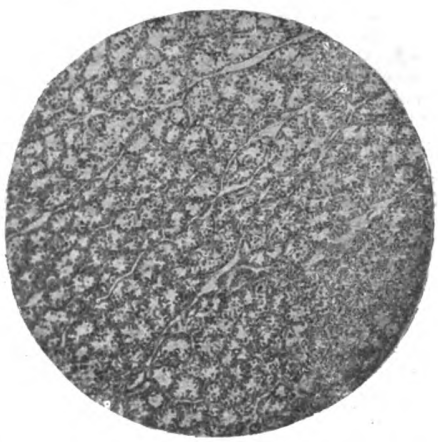

FIG. 4.

A third type of gland is depicted in Fig. 3, and is entirely different from 1 and 2. The vesicles are small, and contain little or no secretion. Their contents take the form of a perfectly clear, unstained, or of a faintly stained, granular material. The secreting cells are very large and prominent; the nucleus is large and situated at the basal part of the cell, there being a wide free margin of faintly granular protoplasm. In some vesicles the lumen is not shapely defined, the granular secretion in the vesicles being apparently continuous with the similarly stained protoplasm of the outer part of the secreting cell. The nuclei of the secreting cells are unequally stained, some of these presenting a pale granular appearance. The gland appears more vascular than either of the foregoing, capillaries and large vessels being alike prominent. This type of gland was present in five of the series.

Yet another type of gland is illustrated in Fig. 4. The appearance here is different from all the foregoing and at first sight is not readily recognisable as thyroid tissue. The secreting cells are swollen and distorted and many are detached and lie free in the lumen. There is no colloid. On high-power examination it is also seen that the majority of the secreting cells are swollen, distorted, and detached; others are smaller in size and are represented by a very small deeply stained nucleus with a small amount of granular protoplasm around. There are few blood-vessels. This type of gland was present in four of the series.

Explanation of the different appearances.—These results therefore show that the minute structure of the thyroid gland in apparently healthy wild rats differs widely in different animals. The differences must, it seems to me, be explained in one or other of the following ways. Either the appearances represent different stages of activity of the gland comparable to those observed in other secreting glands, these variations being dependent on the stage of secretion, or they represent modifications in the structure and functions of the gland which have been induced by dietetic or other factors in the animal's environment. The former explanation seems not to hold good, since a careful investigation into the nature of the stomach contents in the different animals, along with a consideration of the microscopic appearances of the thyroid in each case, has yielded evidence against it. For instance, the appearances of the gland shown in Fig. 1 were observed both in animals in which the stomach was full and also when it was empty. And again, the different appearances represented in Figs. 3 and 4 were alike observed in animals in which the stomach was about one-third full, while in other animals with an equal amount of stomach contents the condition of the thyroid gland was entirely different from both.

The second explanation seems, therefore, to be the more probable, the effects observed indicating that modifications in structure and function of the thyroid gland occur in association with different environmental conditions. In view of the fact recently demonstrated by the writer, that certain diets modify the structural appearances of the thyroid gland in tame rats, it is reasonable to think that diet may have been the chief factor in inducing the modifications of structure described in the present paper. In this connexion it is of interest to note that it was observed that the thyroid gland of all the animals from any one source invariably presented the same general characters. The point, however, is one which can only be definitely settled by experiment, and an investigation is at present in progress to determine the correctness or otherwise of the explanation suggested.

Edinburgh.

THE PEOPLE'S REFRESHMENT HOUSE ASSOCIATION, LIMITED.—The thirteenth annual report of this association, which will be submitted to the annual general meeting to be held at Broadway Chambers, Westminster, on April 25th, at 2.30 P.M., shows that the association is steadily extending the field of its operations. At the end of December, 1909, 59 inns were in possession of the association, and 12 were under its management as agent, and were conducted on a system of giving to managers a large share of the profits on non-alcoholic drinks and foods while withholding from them all profits on alcohol. To show how much these reformed public-houses are appreciated by working men, it may be mentioned that at one house at Chislehurst the number of cups of tea served in the bar rose from 707 in 1908 to 2765 in 1909. The profit for the past year was £2468.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

UNUSUAL ENDING IN A CASE OF ARSENIC POISONING.

BY W. J. WEBB ANDERSON, M.D. LEEDS, CH.B. VICT.,
FATSHAN HOSPITAL, WESLEYAN MISSION, CANTON.

MY colleague was called to a case of poisoning due to eating a large piece of native arsenic. On arrival he found a native woman, aged 28 years, in a state of frightful collapse, with much retching and some diarrhœa. He ascertained that on the day before—i.e., fully 24 hours—the woman had a violent quarrel with her husband and had threatened to eat arsenic. This she had done after the evening meal of rice, a fact that accounts perhaps for the delay of the symptoms; about 8 P.M. she felt sick and began to vomit. This continued all night, being followed by slight diarrhœa. Native nostrums were used, but with little avail. Failing improvement we were called in to see the woman. My colleague found a well-nourished and evidently very strong young woman lying on a filthy bed in a filthier room. All native ideas of cure having given out, despair and even callousness took possession of all concerned. At once the failing pulse was stimulated by hypodermic injections, and water being secured the stomach was washed out with quarts of a solution of Condy's fluid. An extraordinary quantity of grass-like material was removed, tasting more like "sour dock" than anything I could remember. What it was I have not so far been able to find out, but hope yet to secure some for identification. With this there were mixed pieces of native arsenic. This is an arsenic earth in which there are, in some specimens, "red earth" (much used in Hong-Kong for building purposes), some traces of lime, and a little sand. The patient having been so far relieved, revived a little, and after four hours hard work upon her the pulse became stronger, the vomiting ceased, the respiration less sighing, and she was altogether better. Removal to the hospital was advised as the best procedure under the circumstances.

On the next day, Thursday, when the patient arrived, she was anæmic; the pulse was fairly strong and 86 per minute, and the respirations were 20. There was slight diarrhœa; no vomiting; no abdominal pain or tenderness was complained of or felt on palpation; there was no fulness or tympanites. Treatment on the Thursday and Friday consisted of periodic washing out of the stomach with the solution of Condy's fluid, doses of peroxide of iron and soda bicarbonate, castor oil (one ounce), and high enemata. On Saturday she was eating well, taking milk and *conjè* (rice water). The pulse was slower, fuller, and quite steady. In the afternoon she sat up; the only thing now complained of was weakness. She had no further diarrhœa and no cramps. During the evening she drank freely of milk and chicken broth, being thirsty. On the Sunday at 10 A.M. she was better; the thirst was less, the pulse good, and the abdomen flat; there was no tenderness on palpation; the heart was good. At 11.30 A.M. a message was sent to me saying that she had passed per rectum some fæces and blood stains. At 11.45 A.M., when seen, the patient said that she had a little pain in the epigastric region near the middle line. The pulse was good. At 12.30 P.M. the pulse was faster and the patient was slightly sweating. She was thirsty, a little paler than previously, and anxious about herself. A hot-water bottle and hot fomentations were applied to the abdomen. She had tincture of opium (25 minims) by the mouth. At 1 P.M. she had another evacuation, almost all dark blood, with very little attempt at clotting. Examination of the abdomen showed only slight pain on palpation. She still complained, however, of abdominal pain. Tincture of opium was injected per rectum, and the hot applications were renewed. About 1.30 P.M. the abdominal pain was agonising; the pulse was fast and bounding, of low tension. She was copiously sweating and there was some collapse. Hypodermics of morphia were given and some cardiac stimulants. A diagnosis of hæmorrhage into the intestinal canal about the region of the

duodenum was made, and the case explained to her Chinese friends. Operation was refused. "If Heaven will not cure, then she must die" was the substance of their philosophy. Bismuth, turpentine oil, and hamamelis were in turn tried, but without success. The patient was evidently bleeding internally into the intestines. This was the more apparent, as again she had a rather large bloody evacuation, and the abdomen, which was still quite flat, now showed where the blood was collecting, as there was a tumour just above the umbilicus in the middle line. Peristaltic action could plainly be seen. The patient bore all the signs of acute internal hæmorrhage, and finally died about 2 P.M.

Remarks.—This case is particularly instructive for several reasons: 1. The apparent recovery of the patient, so that we dismissed our fears. 2. The rapid blood-flow into the intestines set up an agonising colic, the peristaltic action only moving on the coagulum to allow of fresh blood flowing, to be followed by a further spasm. 3. The bleeding was evidently very high up in the small intestine, as so small a quantity of partly digested blackish blood was passed per rectum. 4. The bleeding into the intestine (probably the duodenum) is not at all usual. Books and recent literature point out that the duodenum may be bright red, the redness being "due to minute petechiæ" (see Sedgwick's case [1]). But to have a copious hæmorrhage into the intestine—the tumour thus formed visibly enlarging under one's own sight, so marked that my Chinese women nurses again and again drew attention to it—is very unusual. A post-mortem examination was out of the question; indeed, I think a sure way to secure a riot would be to suggest and perform one or two. I conclude that some of the arsenic in the form in which it was eaten had passed into the intestine and had eventually caused acute hyperæmia and then ulceration sufficiently deep to cause some artery to give way. The weakness of this record is in the absence of the post-mortem examination, but things have hardly advanced so far in China—certainly not in this anti-foreign city of Fatshan.

Fatshan.

NOTE ON AN INTERESTING CASE OF CEREBRAL TUMOUR.

BY P. CRAWFORD CONRAN, M.R.C.S. ENG., L.R.C.P. LOND.,
HOUSE PHYSICIAN TO THE MIDDLESEX HOSPITAL.

THE patient, a man, 33 years of age, was admitted to the Middlesex Hospital under the care of Dr. J. Kingston Fowler on Oct. 2nd, 1909. His mother had died from cancer, but otherwise the family history was good. The personal history showed that, with the exception of gonorrhœa on several occasions, there had been no previous illnesses. The patient had always been of a somewhat sleepy disposition, but possessed sufficient intelligence to enable him to manage a large business successfully. In October, 1908, he had many business worries, under the strain of which his health suffered, and he was sent to Margate for a fortnight to recuperate. He returned in a much improved condition, both of mind and body, and until May, 1909, enjoyed fairly good health, taking an active share in the conduct of his business and entering keenly into his usual recreations, of which the chief was rowing. In May the patient's business partner noticed that he had fits of drowsiness. On several occasions during each day he would fall asleep for half an hour at a time, and this symptom became more and more marked as time went on. Sometimes he would fall asleep during his meals, often with a glass in his hand. Usually a rather careful man with regard to money matters, he became reckless and extravagant. For example, he ordered an expensive motor-car, for which he could not pay and which was quite unnecessary. Formerly a man of fastidious taste as to his personal attire and cleanliness, he now became slovenly and careless, and his gait, formerly alert, was now shuffling. Finally, at midday on Oct. 2nd, 1909, a policeman found the patient lying on the pavement in an unconscious state and brought him to the hospital, where he was admitted in a dazed condition with a cut on his chin caused by the fall.

On admission the patient complained of a severe headache, and would only answer in monosyllables after a question had been repeated several times. He was aware of the fact that he was in a hospital, but could give no account of what happened before or after his fall. The pupils were dilated and equal; they reacted sluggishly to light, but well to accommodation. The knee-jerks were present and exaggerated on the right side. The plantar reflex was extensor on both sides, and there was no spasticity. Romberg's sign was present, the patient falling backwards. The pulse was of low tension, and the rate 80 per minute. On the next day at 3 A.M. he became restless and tried to climb out of bed. His pulse was now full and strong, and the respirations were more rapid. He again complained of headache and was given half a drachm of potassium bromide, after which he was more quiet. At 6 A.M. he developed a marked internal squint, which was only present for a few minutes. The pulse dropped to 68 per minute, and respiration became of the Cheyne-Stokes type. The pupils were widely dilated and inactive to light. The limbs were now slightly spastic, the knee-jerks more exaggerated on the left side, and the extensor plantar reflexes more marked. Urine was passed in the bed. The temperature, 98° F. on admission, was now 101·2° and rising steadily. The spasticity gradually passed off and the pulse became more forcible. At 1 P.M. the temperature was 103·5°, the face flushed, breathing stertorous, and the head turned persistently to the left side. The mouth was drawn up on the left side and the right naso-labial fold was lost. The heart beat rapidly and strongly, the carotids pulsated visibly, and a loud systolic murmur was heard at the apex. The patient was quite comatose, the face became cyanosed, the breathing more stertorous, the temperature rose to 106·6°, and at 2.30 P.M. death ensued.

Post mortem a tumour, firm in consistence and having the microscopical structure of a glioma, was found distending the anterior horn of the right lateral ventricle, being attached to the wall by a pedicle.

[1] THE LANCET, July 30th, 1904, p. 299.

Medical Societies.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

Exhibition of Cases and Specimens.

A CLINICAL meeting of this society was held on April 1st, Dr. NEVILLE T. WOOD, the President, being in the chair.

Mr. E. LAMING EVANS showed a case of Congenital Dislocation of the Hip two years after manipulative replacement. The little girl was 4 years old when she came under his care. A skiagram clearly showed the original condition, the head of the bone being under the glutei, the limb 1¼ inches shorter, and the trochanter 1¼ inches above Nélaton's line. A skiagram of the present condition showed the head in the acetabulum, the borders of which were seen to be particularly shallow in the original skiagram. The leg is the same length as the other, and the child jumps and runs without anything abnormal to be noticed. Mr. Evans described fully his treatment and the reasons for the different positions in which the limb was placed. He pointed out that Trendelenburg's sign was positive, and the importance of this sign in determining if the head was held firmly in the acetabulum. The mobility in the joint was complete. He said that the two principles recognised in the retention of the head in the acetabulum were: (1) muscular retraction and contraction; and (2) fibrous ankylosis. The cure in this case was obtained by the principle of the former method.

Mr. DUNCAN C. L. FITZWILLIAMS showed: 1. A case of Congenital Dislocation of the Left Knee in a child aged 1 year. There was severe talipes equino-varus in the left foot; genu valgum and genu recurvatum; the head of the tibia was dislocated upwards and outwards. Flexion was very imperfect. The presence of a patella was doubtful. The child had been operated on a month ago for strangulated right inguinal hernia. The hernial sac contained small intestine in which were such large hard scybalous masses that the intestine could not be returned without breaking them up. They must have formed in the sac. The child was one of twins. Mr. Fitzwilliams intended to keep the knee flexed for a prolonged period after reducing the dislocation. 2. A case of Traumatic Dislocation of the Knee.

The patient was knocked down by an engine and sustained the following injuries. Several ribs on the left side were broken; there was pneumothorax with blood in the pleural cavity, and there was extensive emphysema on the left side. The left humerus was fractured and the left hand was crushed. The left knee was completely dislocated; the head of the tibia was displaced upwards about 3 inches, lying internal to and behind the femur. The subcutaneous tissue was freely displayed in places, but none of the wounds communicated with the joint. After he had recovered somewhat from the shock the dislocation was easily reduced under spinal analgesia, stovaine being used. The patient, who is aged 31 years, now walks two miles to have his arm massaged.

Mr. W. MCADAM ECCLES showed: 1. A case of "Infective" Osteo-arthritis of both Knee-joints in a man aged 40 years, a type-founder, a fairly healthy man. He had suffered from lead colic 14 years ago, but there had been no recurrence since. There was no history of venereal disease and no signs of tabes. There were pain and difficulty in walking, and the gait was that of catching up the centre of gravity. The teeth had been very defective for years. If the disease had been only in one knee Mr. Eccles would have advised excisions. There was no increase of fluid in the joint. 2. A case of Charcot's Disease of the left Knee-joint in a man aged 34 years. He had had syphilis 17 years ago. The condition came on after straining the left knee eight months ago. There were increase of fluid in the joint, lateral mobility, and alteration of the bones. There were signs of tabes dorsalis. 3. A case of Cystic Swelling of the Abdominal Wall in the left inguinal region in a girl aged 10 years. The swelling was noticed by the mother a short time after an indefinite history of a blow on the abdomen supposed to have occurred three months ago. The case was exhibited for diagnosis. Mr. Eccles, who thought it was probably due to a partial rupture of the lower part of the left rectus abdominis, said that he should explore if improvement did not soon occur.

Dr. FREDERICK S. PALMER showed: 1. A case of Traumatic Epilepsy successfully treated by operation. The right parietal bone was fractured in 1898. In 1904 the patient fell and struck the same region. In 1905 he entered the army. In February, 1906, in India, he began to have epileptic seizures and became hemiplegic on the left side. He was trephined; the hemiplegia disappeared, but he had about 16 epileptic fits after the operation, and was invalided home in November, 1907, and discharged as unfit for service. His fits became frequent and headache became severe. A fit seen began by twitching of the right side of the face and neck, followed by chronic convulsions of the left arm and leg, then becoming generalised. On Feb. 17th, 1909, a portion of skull about 2 by 2½ inches was removed, in which were two depressed pieces of bone, evidently the pieces trephined which had been replaced; a flap of dura mater was raised, nothing abnormal being seen on the exposed cerebral surface; the flap of dura mater was sutured, the bone not being replaced, and the scalp was treated as usual. On May 26th the scalp flap was thrown down and a platinum plate was fixed over the opening in the skull by means of a platinum wire. From the operation until the present there have been no headaches and no epilepsy. The patient was shown at the Medical Society in November, 1909. 2. A case of Monoplegia (Functional) in a girl aged 16 years. In July, 1906, she had an attack of paralysis of the right arm and leg which was cured. Some weeks after returning home she became hemiplegic on the right side without aphasia; this attack also disappeared under treatment by massage and electricity. She remained well after this until the present attack which began in January, 1910. Now there was a flaccid type of paralysis of the right arm; the wrist was flexed and the fingers were strongly flexed over the thumb; all the flexures could be straightened out under gentle pressure. Anæsthesia extended to the elbow. No abnormal nerve signs were present, except that the biceps, triceps, and supinator jerks were diminished and the plantar reflex was absent on the right side. The patient was steadily improving under treatment by massage and static electricity.

Mr. ASLETT BALDWIN showed a case of "Fracture Dislocation" of the Right Shoulder. The radiograph produced showed a fracture through the anatomical neck with the head of the bone beneath the coracoid process. Mr. Baldwin cut down and found a fair amount of capsule attached to the head; so he reduced the dislocation and wired the bones. The wound healed by first intention and there was now very fair movement in the joint. The head appeared to have united to the shaft and to show no sign of wasting.

Mr. CECIL H. LEAF showed: 1. A man, aged 55 years, from whom he had removed three inches of the transverse colon containing a growth, microscopically Myosarcoma. He had been struck in the abdomen one year ago by the pole of a wagon; symptoms were first noticed about four months ago. Mr. Leaf thought the growth owed its origin to the blow. 2. A man, aged 67 years, to show what a great amount of comfort and advantage might be derived from repeated cauterisations in cases of inoperable carcinoma of the tongue. In this case the tongue and inside of the mouth were clean and the man had had no pain since the first cauterisation.

A case of Mr. F. SWINFORD EDWARDS, of Tumour of the Jaw, was shown for diagnosis.—Mr. ASLETT BALDWIN considered that it was probably a case of malignant disease, pointing out that in parts the disease ended abruptly, not fading into the tissues as it would do if inflammatory.—Mr. H. LLOYD WILLIAMS thought that a conclusive diagnosis could not be made. It might either be entirely inflammatory or a new growth complicated by septic infection.

Dr. GEORGE PERNET showed a case of Lichen Planus treated with the Ultra-violet Rays.

Mr. J. C. MARKLOVE showed (for Mr. R. B. ETHERINGTON-SMITH) the case of a man with an Enlarged Right Knee-joint, presumably one of Charcot's disease. There was much fluid. There was no history of trauma. The man denied venereal disease, and had an Argyll Robertson pupil and exaggerated left knee-jerk. The onset was gradual.

Dr. RAYNER BATTEN gave a demonstration of the Hydro-ophthalmoscope, an instrument for the examination of the eye under water. He also pointed out the use he had made of it in the treatment of some diseases of the eye.

Dr. H. MACNAUGHTON-JONES showed six specimens of Uterine Myomata illustrative of degenerative changes.

LIVERPOOL MEDICAL INSTITUTION.—A meeting of the Pathological Section of this society was held on April 7th, Dr. T. R. Bradshaw, the President, being in the chair.—Dr. Leslie Roberts and Dr. F. P. Wilson showed sections of Lichen Planus and Pityriasis Rubra.—Dr. J. Lloyd Roberts showed a section of Endothelioma under the skin following puncture of the pleura.—Mr. F. A. G. Jeans showed 4 feet of Jejunum removed from a man who had been run over, which had perforated; also 3 feet of Ileum removed from a woman with a strangulated ventral hernia. Lateral anastomosis was performed in both instances, and both patients recovered.—Dr. R. E. Kelly showed: 1. A large Urethral Calculus measuring 1 inch in diameter removed from a man on whom perineal section had been performed 11 years previously. 2. Molluscum Contagiosum from the calf of a boy, aged 11 years; it was alleged that the condition was present at birth.—Dr. D. Moore Alexander showed four sections of Retained Testicles removed from subjects aged respectively 8, 13, 24, and 36 years. They showed the gradual fibrotic changes occurring around the tubules and the degeneration of the cells lining the tubules.—Dr. A. G. Gullan and Dr. P. Hick showed a case of Primary Carcinoma of the Right Lung from a woman aged 46 years, which had caused solidification of the right lung and obstructed the superior vena cava and invaded the pericardium.—Dr. J. Owen and Dr. Hick showed a Contracted Stomach, 5 inches in length, the cardiac half admitting the small finger, obtained from a man six weeks after taking spirits of salts. Microscopically the mucous membrane was completely destroyed.—Mr. D. Douglas-Crawford showed: 1. A large Cystic Kidney, probably congenital, removed from a woman, aged 42 years, who had apparently suffered from hæmaturia and renal colic. There was no evidence of cystic disease of the other kidney. The cysts were filled with colloid material and the walls lined with epithelium, cubical or flattened. 2. Meckel's Diverticulum in a Right Inguinal Hernial Sac, which was adherent to the testicle.—Dr. J. E. McDougall showed a specimen of Angioma of the Pyriform Sinus of the Larynx, which had originated at the site of, or in the immediate vicinity of, a foreign body removed by himself several months earlier.—Dr. R. J. M. Buchanan and

Dr. Ernest E. Glynn showed a specimen of Enlarged Tuberculous Bronchial Glands from a man with Mitral Stenosis.—Dr. Glynn also showed a Brain with Diffuse Subarachnoid Hæmorrhage. Also the Lungs from a boy who died from acute pneumococcal septicæmia after an illness of apparently only five hours' duration. There was no pneumonia.—Dr. F. P. Wilson read a note on the Presence of Acid-fast Bacilli in the Stools in Tuberculous Conditions, with special reference to Lupus Vulgaris. He drew attention to recent work which showed that the presence of acid-fast bacilli in the stools was not necessarily due to intestinal ulceration or swallowing of sputum, as they had been found in cases of tuberculous diseases of the joints, glands, and meninges. He had himself examined the fæces of 10 cases of lupus vulgaris by means of smears and also by injection into guinea-pigs. In every case the result was negative. He suggested that further research might meet with success in cases of toxic tuberculides.——A meeting was held on April 14th, Dr. Bradshaw, the President, being in the chair. The first part of the evening was devoted to the exhibition of clinical cases.—Dr. G. G. Stopford Taylor and Dr. R. W. MacKenna communicated a paper on the Spirochæta Pallida. They gave a short history of the introduction of syphilis into Europe and of the various attempts which had been made to discover the organism of the disease before the famous discovery of Schaudinn in 1905. The spirochæta was described in detail and many fine microphotographs were shown of the organism obtained from Dr. Taylor and Dr. MacKenna's pathological material. Its life-history was then described and the gaps in scientific knowledge were pointed out.—Dr. W. T. Prout, alluding to frambœsia or yaws, said that some considered this disease to be a form of syphilis. He did not think this view was accepted by those who worked in the tropics. He considered that protozoal diseases were characterised by some similarity of symptoms.—Dr. E. E. Glynn showed some excellent Microphotographs of the Spirochæta.

LEEDS AND WEST RIDING MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 8th, Dr. J. B. Hellier, the President, being in the chair.—Dr. Bedford Pierce read a paper on Diagnosis in States of Depression.—Dr. E. F. Trevelyan showed a man, aged 46 years, with Lymphatic Leukæmia of about a year's duration. There were some anæmia and widespread though moderate lymphatic enlargement. The tip of the spleen could be felt. The blood count showed 97 per cent. lymphocytes (small mononuclear) of 180,000 leucocytes per cubic millimetre. The red cells stood at 2,700,000.—Dr. Trevelyan and Dr. J. Allan showed a man, aged 53 years, a carpenter, who had been subject to attacks of Painful Tonic Spasm in the Hands in the winter during the past 17 years, the first attack being noted while he was convalescing from pleurisy. The attitude assumed by the hands was that of tetany, but the signs called after Chvostek, Trousseau, and Erb were all absent. There were no noteworthy gastro-intestinal symptoms.—Mr. G. Constable Hayes showed a lad, aged 17 years, with Double Glaucoma. Three months ago while working below surface in a pit he noticed colours around the lights; shortly after sight gradually became affected. He was seen three weeks ago; there was then no injection; T. + 1 in both eyes; the anterior chambers were normal; there was glaucomatous cupping of both discs. The pupils were semi-dilated. Under eserine the pupils did not contract well. T. + 1. On March 25th iridectomy was performed on the right eye. Tension remained − 1 for a week, but had since then gone gradually up again and was now much the same as before the operation. The patient's father, who became totally blind at 30 years of age from chronic glaucoma, was also shown.—Dr. T. Wardrop Griffith and the President showed a woman suffering from Leucocythæmia. The spleen, in addition to being greatly enlarged, was prolapsed and freely moveable about the abdomen, being palpable per vaginam.—Mr. B. G. A. Moynihan showed a specimen of Primary Colloidal Carcinoma of the Gall-bladder removed for rupture.—Dr. C. Oldfield showed a specimen of Pyosalpinx with twisted pedicle removed from a girl, 18 years of age, who had had five or six attacks like acute appendicitis during the preceding 12 months. The condition was bilateral and on the right side there was a pedicle twisted through two complete turns. The ampullary part of the oviduct alone was distended. The macro- and microscopic appearances were those of tubercle, but no bacilli were found. The uterus and ovaries were preserved and the patient made a good recovery.—Dr. A. Bronner showed a case of Hypopyon Ulcer of the Cornea in an adult treated with pyocyanase, dropped in hourly; the symptoms rapidly improved. Dr. Bronner had treated several cases of ulcer of the cornea with pyocyanase drops, and they had all improved very rapidly.—Dr. E. O. Croft showed: 1. A specimen of Fibrosis Uteri removed by vaginal hysterectomy from a multipara, aged 54 years. Persistent menorrhagia had existed for many years in spite of much treatment, including curetting. The uterine walls were uniformly thickened, and the microscope revealed an excessive amount of connective tissue, especially well marked around the blood-vessels. 2. The Uterus and Appendages removed by abdominal hysterectomy for Squamous Epithelioma of the Vaginal Portion of the Cervix. The growth was present superficially on the vaginal portion and had extended somewhat on to the vaginal walls. The cervical canal was healthy. The tissues immediately beneath the ulcer were infiltrated, but there were no deposit in the broad ligaments and no enlargement of the glands. The whole of the palpable disease was easily removed.—Mr. G. P. Anning showed photographs of a Congenital Thoracic Deformity—absence of the left mamma and nipple and the sterno-costal part of the pectoralis major.—Cases and specimens were also shown by Mr. H. Littlewood, Mr. J. F. Dobson, Mr. H. Collinson, the President with Dr. Isaac Taylor, Dr. R. A. Veale, and Dr. W. H. Maxwell Telling.

SOCIETY OF MEDICAL OFFICERS OF HEALTH.—A meeting of this society was held on April 8th, Dr. H. Cooper Pattin, the President, being in the chair.—A paper was read by Mr. C. S. Loch upon the proposals in regard to medical relief made in the Majority Report of the Royal Commission on the Poor-laws and the Relief of Distress, in which he dealt first of all with the present position of medical relief and its organisation, then with the general and other recommendations of the majority of the Commissioners, and lastly with the sufficiency of their suggestions in relation to the organisation of public health. He considered that a free system of medical relief paid for by the State and the transformation of the medical men of the country into a very large State staff was open to the gravest objection. It would run counter to the healthy growth of our social structure, and would weaken social effort, in which lay ultimately the foundation of health and of well-being. In fairness to the profession the rule should be everywhere adopted that the patient should pay according to his ability. The justice of this was self-evident, and it followed that at every hospital or infirmary or Poor-law dispensary, or in connexion with all the forms of outdoor medical relief, there should be payment. Very much could be done to deal with coming illness at the earlier stages. The people could be educated to think. Every centre of medical relief could be used, not merely for curative and alleviative, but also for preventive, purposes. Dr. R. W. Philip's dispensary in Edinburgh had shown what could be done in relation to phthisis by specialisation and visiting, but the system was not applicable to phthisis only. It suggested a form of coöperation between persons and authorities which might be introduced into other branches of medical treatment. The Majority proposals included the voluntary hospitals and dispensaries, and did not exclude the large sick-club organisations. They made assistance available all along the line, and to avoid needless duplication of officials they made one system of Public Assistance serve for medical relief whether it was of adults or of children, and they brought voluntary assistance into relation with it also. The solution of the problem lay in unification or association, with a recognition of differences of function.—Dr. A. H. Bygott considered that using the history of the evolution of our national elementary education system as an analogy good results might be obtained by organising our public medical services on proper coördinating lines so that they would form one public medical service, using voluntary charities as far as possible in a similar way to that in which voluntary schools were used. In this way responsibility would be laid on one pair of shoulders, and the sick person needing relief would know exactly where to go to obtain it.—Mr. F. E. Fremantle rejoiced that the Majority proposals, like those of the Minority, relied so much on prevention. The realisation of either was thus a question of practicability. Those of the Minority

were based upon ideals; those of the Majority were built up from existing conditions.—Mr. E. H. T. Nash considered that in the discussion of any scheme invalidity insurance would have to be reckoned with.—Dr. F. S. Toogood urged that there ought to be no rivalry between the Poor-law medical officer and the medical officer of health. He considered that a fatal blow had been struck when justices of the peace were no longer *ex-officio* members of boards of guardians, and he was of opinion that these bodies had very much deteriorated. He advocated larger areas of administration, and more specialisation.

NORTH OF ENGLAND OBSTETRICAL AND GYNÆCOLOGICAL SOCIETY.—A meeting of this society was held at Manchester on Friday, April 15th, Dr. W. K. Walls (Manchester) being in the chair.—Dr. W. E. Fothergill (Manchester) showed a large Fibroma of the Ovarian Ligament and Contiguous Portion of the Ovary. It was markedly infiltrated with blood caused by torsion of its pedicle. This had been associated with symptoms of a subacute nature, and the patient was admitted to hospital. Two days later, whilst waiting for the usual operation day, she was suddenly taken ill and presented all the signs of internal hæmorrhage. The abdomen was opened within half an hour; it contained a large quantity of free blood which had escaped from a vessel at the seat of torsion. The tumour was very easily and quickly removed, and the abdominal cavity was filled with saline. Though the patient rallied and improved for some hours she died next day.—Dr. E. O. Croft (Leeds) recorded a case of Cæsarean Section for a Post-rectal Cyst, which markedly bulged the posterior vaginal wall and displaced the cervix upwards, so that the external os was on a level with the top of the symphysis. Rectal examination showed that the cyst was behind and to the right of the bowel. Pelvic pressure symptoms during the seventh month led to detection of the cyst. Cæsarean section was performed at the estimated full time. After the uterus had been sutured the patient was put into the Trendelenburg position. The cyst was found to be of the size of an orange. The rectum curved over its surface on the left side, whilst on the right side the iliac vessels and the ureter lay in front of it. It was considered unwise to attempt its enucleation from above, so the abdomen was closed. Three weeks later the cyst was opened by an incision through the vagina, a large rectal bougie being placed in the bowel as a guide. Three or four ounces of slightly turbid albuminous fluid were drawn off. It contained neither ordinary dermoid products nor hydatid elements. Finally the cavity was packed with gauze. Ten days later only a slight indistinct thickening could be detected.—Dr. H. Briggs referred to two cases in which he had been able to remove similar thin-walled retro-peritoneal cysts by a perineal dissection between the anal canal and the coccyx.—Dr. Fothergill suggested that such cysts are derived from Wolffian relics.—Dr. H. Clifford (Manchester) showed a Pregnant Uterus containing a Fibroid, and recounted the interesting obstetrical history of the case. On four occasions the tumour, which had enlarged during pregnancy, had almost disappeared within a few weeks after its termination, by forceps on the first two occasions, by forceps after induction at the eighth month on the third, and by Cæsarean section on the fourth. The same variations in its size were noted in association with two later pregnancies which had ended in early abortions. Finally, when pregnant again the patient refused to wait for Cæsarean section, and enucleation proving impossible the uterus was removed.—Dr. H. Leith Murray (Liverpool) read a paper on Red Degeneration of Fibroids, and detailed four cases of the condition. Three of these were unassociated with pregnancy and were producing no symptoms of urgency, while the fourth, occurring in pregnancy, was of a more urgent type. All showed defective nuclear staining, some hyaline and granular changes, and thrombosis in a few small vessels. Two of them were proved sterile, both aerobically and anaerobically. An account of the hæmolytic properties of the lipoids extracted from four degenerating fibroids was given, together with a demonstration (1) of a peculiar bleaching which develops when lipoid is added in excess of the quantity required for complete hæmolysis; and (2) of the inhibitory effect of blood serum on this process. The conclusions were drawn that red fibroids are not a group by themselves, that thrombosis is not primary, and that many of the old stains in degenerating fibroids, not necessarily *red* stains, may be due to old symptomless hæmolysis.

BRIGHTON AND SUSSEX MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held on April 7th, Mr. C. J. Jacomb-Hood being in the chair.—Dr. F. J. Poynton read a paper entitled "Some Observations on Infective Arthritis." It was divided into two parts, the first, a lantern demonstration on the pathology of arthritis; the second, an outline of the mode of treatment viewed by the light of pathological advance. Dr. Poynton emphasised the difficulty of isolating micrococci from arthritic exudations in subacute arthritis. This was true alike in man and animals. Very early acute effusions might be sterile. Subacute effusions with many leucocytes in the exudation were also often sterile. The infective agent was deposited in the synovial membrane and was most likely to be found in the exudation when the process was suppurative or sero-fibrinous. He next demonstrated that a micrococcus—namely, the micrococcus rheumaticus—might, under varying degrees of virulence, produce in animals acute arthritis, peri-articular arthritis and osteo-arthritis, and brought forward proof of the causal part that this micrococcus played in rheumatism by showing the growth of this micro-organism in the pericardial exudation from a case of rheumatic hyperpyrexia, and in the pericardial fluid from an experimental pericarditis in a rabbit produced by inoculation of the human pericardial fluid. Dr. A. Paine and he had been indebted to Dr. Lauriston Shaw and Dr. A. F. Hertz of Guy's Hospital for the case of hyperpyrexia. In the second part of the paper Dr. Poynton touched upon serum and vaccine treatment in infective arthritis, upon Bier's method of passive congestion, cataphoresis, radiant heat, also upon massage and various methods of internal treatment. The outcome of these observations was to the effect that serum and vaccine therapy were as yet far from reliable, and Bier's method of passive congestion often disappointing. Cataphoresis and radiant heat in subacute arthritis of the rheumatoid type were sometimes of marked service.

NOTTINGHAM MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held in combination with the Nottingham division of the British Medical Association on April 5th, Dr. A. Fulton being in the chair.—Dr. F. H. Jacob remarked on the mysterious pathology of Diabetes Insipidus, a disease in which excessive polyuria was accompanied by progressive wasting. He related one case where the only pathological lesion was cystic disease of both kidneys. Another case, a lad aged 19 years, used to pass from 10 to 15 pints of urine of a specific gravity of 1002 daily. The urea estimate was only 0·46 per cent. After some months this patient developed optic atrophy and became blind. This led him to favour the theory that the disease was due to diminished secretion of the anterior or glandular lobe of the pituitary body, as a tumour of this lobe would cause diminished secretion and experiments of excision of this lobe in dogs were followed by excessive polyuria.—Mr. W. M. Willis, in a short paper on some cases of Intestinal Obstruction, demonstrated the use of the sigmoidoscope. Of intestinal carcinomata 80 per cent. occurred in the rectum and lower sigmoid, 15 per cent. in the rest of the large intestine, and 5 per cent. in the small intestine. These figures showed the great use of this instrument. The instrument needed care in its introduction, for perforation of the bowel had been caused by it. Mr. Willis introduced it with the patient in the knee-elbow position and did not use anæsthesia. Mr. Willis then showed a specimen, sarcoma of the sigmoid, removed 12 months ago, after the diagnosis had been made with the sigmoidoscope.

PATHOLOGICAL SOCIETY OF MANCHESTER.—At a meeting of this society held on April 13th a discussion on the Chronic Results of Septic and Gonorrhœal Infection of the Female Pelvic Organs was opened by the President, Dr. W. E. Fothergill, who considered the parts played, as sources of infection, by the appendix, the rectum, and other portions of the intestinal canal, by the blood-stream, and by blood effused into the pelvis. The routes by which infection spread within the pelvis and the inflammatory reactions of the various tissues were discussed. It was suggested that septic infection produced lasting results by producing fibrosis of various structures and organs rather than by inaugurating true chronic infection. Thus "chronic septic endometritis" and "metritis" were indistinguishable pathologically from other conditions which were not infective in origin but in

which fibrosis was a leading feature. Gonorrhœal and mixed infections, on the other hand, might be truly chronic in character. One bar to the spread of gonorrhœal infection was presented by the vagina, another was afforded by salpingitic closure of the abdominal openings of the tubes. Was there not a tendency to neglect cases in which gonorrhœal infection sealed up the tubes and caused sterility and other symptoms without producing gross lesions, such as pyosalpinx? And, gonorrhœa apart, would it not be well to open the abdomen more frequently in old infective cases without strikingly obvious physical signs in order to separate adhesions, remove diseased portions of ovaries, and make new openings in sealed tubes?—Dr. D. Lloyd Roberts, Dr. A. Donald, Dr. A. H. Burgess, Dr. A. W. W. Lea, Dr. J. H. Ray, Dr. F. C. Moore, Dr. W. K. Walls, Dr. G. E. Loveday, Dr. W. F. Shaw, Dr. H. Clifford, Dr. E. Vipont Brown, and Dr. P. R. Cooper took part in the discussion.

Reviews and Notices of Books.

Male Diseases in General Practice: An Introduction to Andrology. By EDRED M. CORNER, M.C. Cantab., F.R.C.S. Eng., Surgeon to St. Thomas's Hospital. London: Henry Frowde, Oxford University Press. 1910. Pp. 462. Price 15*s.* net.

IT cannot with reason be urged that the study of the surgical diseases of the male generative organs (even if those affecting the bladder were included) presents such an important field of knowledge as gynæcology. The scope of work in the one sex can never, for obvious reasons, approach that of the other. But if we admit this, we must admit also that by no means sufficient attention has been paid in the past to the surgical diseases of the male organs. There has been no lack of scattered information and scattered details of surgical practice, but the sources of knowledge have been either diffused in general text-books of surgery or pent up in treatises on venereal disease. This volume is avowedly addressed to the general practitioner, and though the man in general practice sees perhaps less overt venereal disease than he did a quarter of a century ago, there is more necessity to be alive to the existence of latent gonorrhœa in both sexes, and the proper field for detection and arrest of this condition is the male genital tract, for "the lives of many women are spoiled through the unconscious ignorance of the men they marry." This fact alone is sufficient plea for the book.

If the arrangement of his matter by Mr. Corner appears at first glance somewhat artificial, it is unquestionably that adapted to systematic teaching, as it is based on purely anatomical grounds. In such a treatise the advantage is obvious, for the instruction afforded is surgical and the surgical operations demanded and described are mostly simple in character and scope, far more simple than many surgical manœuvres which are necessarily and constantly undertaken in the case of female diseases by general practitioners. Attention is directed first to conditions of the tunica vaginalis; and in 50 pages devoted to hydrocele and kindred conditions there is plenty of valuable information very well arranged. A chapter on the physiology of the testicle is followed by six chapters on the pathological conditions of the testicle itself. Some of the best matter in the book is embodied in the consideration of operations on the imperfectly descended testicle. The difficult questions which arise as to the proper procedure to be adopted towards an undeveloped or imperfectly descended testicle are well thought out, and the advice is judicious and conservative in tone. If there has been a tendency to remove all undescended testicles on the ground that they are liable to become the seat of malignant disease it has been based on illogical grounds. The malignant deterioration and the malposition are both the result of deficient development; attempts to improve the development of the gland by fixation of the testicle are based on imperfect reasoning.

The consideration of the subject of varicocele is very sound and in accordance with the best modern views: "Only treat those who need it." A careful summary is given of the remote results of operation for varicocele. The only operation undertaken or advised is by means of the open method and an inguinal incision. In a large proportion of cases operation has been enforced by the requirements of the military services, many of the subjects having little or no varicocele except in the estimation of the examining officers of the recruiting staff. The "cure" of the varicocele is in a large proportion of persons merely the removal of a local source of neurasthenic symptoms.

Greater care in writing would have rendered in some places valuable matter more readable. The author considers the relation of the imperfect descent of the testicle to its liability to infective orchitis; but the paragraph is almost unintelligible to us unless the word "rarely" is supplied in one passage. The chapter on the physiology of the testicle is very abrupt in expression and might be better arranged in matter; the last sentence in the chapter has no verb at all. The sections devoted to the secretions of the gland are also jerky, and the expression "for instance" is found on every page, suggesting that the author has not taken any great pains in emending what he has once set down. These lapses of style on the author's part are interesting, for they may illustrate the specialism of his mind: on surgical topics he expresses himself clearly, tersely, and well; when he approaches the physiological, medical, or mental aspect of his matter he becomes hurried and difficult to follow.

The volume is well printed and admirably illustrated and will prove a valuable book of reference in the library of general practitioners.

The Melanesians of British New Guinea. By C. G. SELIGMANN, M.D. Lond. Cambridge: University Press. 1910. Pp. 766. Price 21*s.* net.

ANTHROPOLOGY has of late years become a serious science, and it is no longer the fashion to regard savage and primitive customs as did an Elizabethan translator of Herodotus, or, rather, of his first two books. For he made a marginal note as to a statement of Herodotus about some Egyptian custom to the effect that the reader should "Observe ye Beastly Devices of ye Heathen." Nowadays we have learned by careful comparison that many heathen and primitive customs are full of profound meaning and information as to curious survivals existing among ourselves. The children of our own day, where not spoiled by over-education, go through stages of savagery both mentally and, so far as is possible in this country, physically. The cave-dwelling stage, the wedding and funeral games, the "make believe" attitude, are all remnants of the savage mind.

All readers of Mr. Kenneth Grahame's charming book, "The Golden Age," will recollect the story of "The Whitewashed Uncle." The children were anxious to show that they had misjudged their relative, and Edward said, "We'll christen the piebald pig after him—the one that hasn't got a name yet. And That'll show we're sorry for our mistake." Now hear Dr. Seligmann upon the Roro speaking tribes of British New Guinea, p. 255: "Children are named when quite young, and it is usual for a child of either sex to receive two names, the second being its father's first name, and the first the name of a relative or of any plant, animal, or natural feature that might please the parents. It was considered a compliment to choose a friend's name, but the friend would be equally honoured if his name were given to a favourite pig." So does the East meet the West by going back to primitive custom.

Dr. Seligmann's work is brimful of information upon religion and social customs, and geographical and ethnological matters. Perhaps the thing which strikes the reader most of all is the extraordinarily complex scheme of regulation and custom under which the tribes mentioned live. The customs and fashions governing marriage, childbirth, society, and religion are so involved and so complicated as to put even German or Austrian court etiquette absolutely into the shade. Dr. Seligmann limits the name Papuan to the dark skinned, frizzly haired natives of Western New Guinea, and uses the term Papuasian for the inhabitants of the whole of New Guinea, for, as he points out, the inhabitants of the island may be divided into two distinct races. One difference between these races and white races is that it would seem that impregnation is more difficult in them than in whites, and it seems a native belief that one act of coitus is insufficient for conception. This at least is the belief among the Southern Massim. Cannibalism apparently still exists among the Southern Massim, both in the form of the ceremonial killing and eating of an enemy, and very occasionally in the eating of an exhumed corpse.

As a whole the book is full of interest, it is illustrated with drawings, photographs, and maps, and it has a most excellent index and a glossary. One chapter is written by Captain F. R. Barton, C.M.G., late administrator of the Possession, and the appendix on the Mukaua community is written by Mr. E. L. Giblin.

Industrial Diseases and Accidents. By W. J. GREER, F.R.C.S. Irel., Consulting Surgeon to Pontypool Hospital; Surgeon to Newport and Monmouth Hospital. Bristol: J. W. Arrowsmith. 1909. Pp. 326. Price 7*s.* 6*d.* net.

THE arrangement of this work in alphabetical form is unfortunate, making it appear a series of scraps of information not very well ordered, proportioned, or digested. To produce a book in dictionary form implies that it is a complete book of reference on the subject, which is in this case very far from the truth. Moreover, a book in this form requires cross references, and we look up "Caisson disease," but it is not given under this title, nor is "Divers' paralysis," but both titles have to be found under "Compressed air illness." The cross references to "Ragpickers' disease," "Hadernkrankheit," and "Anthrax" are equally unsatisfactory, and "woolsorters' disease," the oldest title for anthrax, might, we think, have been given as a primary index word.

Such important conditions of industrial injury as concussion of the spinal cord and miners' bursitis are equally difficult to trace. The article "Spine" gives no reference to "concussion," but under the latter heading there are eight lines devoted to this highly important subject. "Miners' elbow" is a well-known term in all English textbooks of surgery, but it is referred to as "beat elbow," which is largely a local expression. We admit that it would be difficult in the limits of a book like this to deal adequately with such a subject as traumatic neurasthenia; but its importance is overwhelming and the subject is deserving of more space than the four pages in which it has been dismissed. Not a word is said about "bichromates," as a reference; we are left to trace the subject under "Chrome." No attempt has been made to give practical utility to the volume by adding a synopsis of regulations affecting dangerous trades. A special section devoted to injuries and diseases of the eye has been assigned to Mr. R. J. Coulter, but the author seems to omit the industrial poisons which produce optic neuritis—such as lead, nitro-benzol, or zinc.

We regret to speak in such uncomplimentary terms of a work to which no doubt much trouble has been given, but we cannot regard the book as likely to be of much service to the medical practitioner. These indexed pieces of information on anatomy and on surgical and medical terms would afford information to solicitors' clerks, overseers, and secretaries to societies, but we cannot imagine a medical man who has any difficulty to face in the diagnosis or treatment of industrial accidents or disease finding much help here. The author, quite probably, has underestimated the grave difficulty of writing a dictionary, to perform which task even moderately well not only a great range of theoretical and practical knowledge is required, but a sense of proportion, order, and responsibility which many a thoroughly skilful professional man may be without. Now such a dictionary, as has been projected, would certainly be very useful, and we suggest that Mr. Greer should work upon this first edition, remedy the omissions, and bring order and proportion into the work. The task would not be easy; but so much labour has been spent that it might be worth while to bring the undertaking to a more satisfactory result.

Atlas der Menschlichen Blutzellen. Von Dr. ARTUR PAPPENHEIM. Zweite Lieferung. Tafel XIII.–XXV. Jena: Gustav Fischer. 1909. Pp. 571 and plates 13–25. Price 30 marks.

WELL may the author quote the old adage, "Tempora mutantur, nos et mutamur in illis." It appears that the plates were drawn and ready many years ago; in fact, a reference to some of them shows that the original drawings were made in 1901 and 1903. The text runs to over 500 pages, and the plates are but 13 in all, and the text is largely explanatory of them. The plates were ready; the text lingered, mainly because of the continual flux of the subject matter itself, and of the diversity of views on the cardinal problems of hæmomorphology. The plates are drawings of leucocytes stained in various ways, with hæmatoxylin as a nuclear stain, combined with various aniline dyes or combinations of such dyes. The author admits that the methods used, though the best available at the time—he speaks of old imperfect methods—are not to be compared in value to the method of Giesma, which he admits is a very superior method, and the one most likely to throw additional light on the structure of leucocytes and the problems of hæmomorphology. The text grew as the author kept on investigating, and so it came about that it was determined to issue this part of the atlas, which is called the "Schluss" or final part, but which appears not to be final. The original number of plates was to be 25, and they were to include the red blood corpuscles and the cells of myeloid leukæmia. They do not do so, and having regard to the great value of the Giesma and other stains, it has been decided to issue a supplementary part, consisting of plates and explanatory text, to complete the work and to give illustrations of staining by the May-Grünwald, Giesma, and other methods. The author apologises for what he considers imperfect lithography in two of the plates.

We have made the author's apologies in his own way for such shortcomings as the book may have; it remains to say that he discusses with fulness, thoroughness, and "gründlichkeit"—we had almost said prolixity—the most varied hæmocytological problems and gives the most intricate details of the structure of cytoplasm and nuclei of the various forms of leucocytes, theresult of his own painstaking and laborious investigations. He concludes that the so-called polymorphonuclear transition forms of Ehrlich, as independent lymphoid cells, are not direct or indirect transition forms and pre-stages of polynuclear granular cells, but are rather the end stage of the development of the large mononuclear leucocyte (splenocyte, lympholeukocyte). The transition forms in normal blood have no amphophil, pseudoeosinophil or neutrophil granules,

but are merely "azurophil" cells. This terminology—and there is much in the work of greater complexity—shows at once how elaborate is the technique. The author seems to favour the theory that lymphocytes and myeloid cells spring from some common "stammzelle" which he calls a hæmatogonia. Most careful descriptions are given of the plates, even to the minutest details of technique, so that many pages of the text may be devoted to one plate.

Part II. (pp. 164–500) contains more descriptions of plates and also deals with the following problems in a very full, precise, and technical manner: theoretical observations on colour theories as to the differential combination of dyes with aniline colours, and on the combination of staining mixtures with the use of basic nuclear dyes; the leucogenic significance of the individual morphological cell types which are described in the text, and the morphological changes in the genetic development of the leucocytes. Finally, there is a long technical chapter on the morphological characters and differences, as well as the respective genetic relations of the different forms of leucocytes to each other, with remarks on the "morphological tinctorial relation" of lymphoid leucocytes in particular to lymphocytes and granular lymphocytes.
